input [array_like] Array_like of values. For each region specified by *labels*, the median value of *input* over the region is computed.

labels [array_like, optional] An array_like of integers marking different regions over which the median value of *input* is to be computed. *labels* must have the same shape as *input*. If *labels* is not specified, the median over the whole array is returned.

index [array_like, optional] A list of region labels that are taken into account for computing the medians. If index is None, the median over all elements where *labels* is non-zero is returned.

Returns

median [float or list of floats] List of medians of *input* over the regions determined by *labels* and whose index is in *index*. If *index* or *labels* are not specified, a float is returned: the median value of *input* if *labels* is None, and the median value of elements where *labels* is greater than zero if *index* is None.

See also:

`label`, `minimum`, `maximum`, `extrema`, `sum`, `mean`, `variance`, `standard_deviation`

Notes

The function returns a Python list and not a NumPy array, use *np.array* to convert the list to an array.

Examples

```
>>> from scipy import ndimage
>>> a = np.array([[1, 2, 0, 1],
...               [5, 3, 0, 4],
...               [0, 0, 0, 7],
...               [9, 3, 0, 0]])
>>> labels, labels_nb = ndimage.label(a)
>>> labels
array([[1, 1, 0, 2],
       [1, 1, 0, 2],
       [0, 0, 0, 2],
       [3, 3, 0, 0]])
>>> ndimage.median(a, labels=labels, index=np.arange(1, labels_nb + 1))
[2.5, 4.0, 6.0]
>>> ndimage.median(a)
1.0
>>> ndimage.median(a, labels=labels)
3.0
```

scipy.ndimage.minimum

scipy.ndimage.**minimum**(*input*, *labels=None*, *index=None*)

Calculate the minimum of the values of an array over labeled regions.

Parameters

input [array_like] Array_like of values. For each region specified by *labels*, the minimal values of *input* over the region is computed.

labels [array_like, optional] An array_like of integers marking different regions over which the minimum value of *input* is to be computed. *labels* must have the same shape as *input*. If *labels* is not specified, the minimum over the whole array is returned.

index [array_like, optional] A list of region labels that are taken into account for computing the minima. If index is None, the minimum over all elements where *labels* is non-zero is returned.

Returns

minimum [float or list of floats] List of minima of *input* over the regions determined by *labels* and whose index is in *index*. If *index* or *labels* are not specified, a float is returned: the minimal

value of *input* if *labels* is None, and the minimal value of elements where *labels* is greater than zero if *index* is None.

See also:

label, **maximum**, **median**, **minimum_position**, **extrema**, ***sum***, **mean**, **variance**

standard_deviation

Notes

The function returns a Python list and not a NumPy array, use *np.array* to convert the list to an array.

Examples

```
>>> from scipy import ndimage
>>> a = np.array([[1, 2, 0, 0],
...               [5, 3, 0, 4],
...               [0, 0, 0, 7],
...               [9, 3, 0, 0]])
>>> labels, labels_nb = ndimage.label(a)
>>> labels
array([[1, 1, 0, 0],
       [1, 1, 0, 2],
       [0, 0, 0, 2],
       [3, 3, 0, 0]])
>>> ndimage.minimum(a, labels=labels, index=np.arange(1, labels_nb + 1))
[1.0, 4.0, 3.0]
>>> ndimage.minimum(a)
0.0
>>> ndimage.minimum(a, labels=labels)
1.0
```

scipy.ndimage.minimum_position

scipy.ndimage.**minimum_position**(*input*, *labels=None*, *index=None*)

Find the positions of the minimums of the values of an array at labels.

Parameters

input [array_like] Array_like of values.

labels [array_like, optional] An array of integers marking different regions over which the position of the minimum value of *input* is to be computed. *labels* must have the same shape as *input*. If *labels* is not specified, the location of the first minimum over the whole array is returned. The *labels* argument only works when *index* is specified.

index [array_like, optional] A list of region labels that are taken into account for finding the location of the minima. If *index* is None, the `first` minimum over all elements where *labels* is non-zero is returned.
The *index* argument only works when *labels* is specified.

Returns

output [list of tuples of ints] Tuple of ints or list of tuples of ints that specify the location of minima of *input* over the regions determined by *labels* and whose index is in *index*.

If *index* or *labels* are not specified, a tuple of ints is returned specifying the location of the first minimal value of *input*.

See also:

label, **minimum**, **median**, **maximum_position**, **extrema**, ***sum***, **mean**, **variance**

standard_deviation

Examples

```
>>> a = np.array([[10, 20, 30],
...               [40, 80, 100],
...               [1, 100, 200]])
>>> b = np.array([[1, 2, 0, 1],
...               [5, 3, 0, 4],
...               [0, 0, 0, 7],
...               [9, 3, 0, 0]])
```

```
>>> from scipy import ndimage
```

```
>>> ndimage.minimum_position(a)
(2, 0)
>>> ndimage.minimum_position(b)
(0, 2)
```

Features to process can be specified using *labels* and *index*:

```
>>> label, pos = ndimage.label(a)
>>> ndimage.minimum_position(a, label, index=np.arange(1, pos+1))
[(2, 0)]
```

```
>>> label, pos = ndimage.label(b)
>>> ndimage.minimum_position(b, label, index=np.arange(1, pos+1))
[(0, 0), (0, 3), (3, 1)]
```

scipy.ndimage.standard_deviation

scipy.ndimage.**standard_deviation**(*input*, *labels=None*, *index=None*)

Calculate the standard deviation of the values of an N-D image array, optionally at specified sub-regions.

Parameters

input [array_like] N-D image data to process.

labels [array_like, optional] Labels to identify sub-regions in *input*. If not None, must be same shape as *input*.

index [int or sequence of ints, optional] *labels* to include in output. If None (default), all values where *labels* is non-zero are used.

Returns

standard_deviation
[float or ndarray] Values of standard deviation, for each sub-region if *labels* and *index* are specified.

See also:

label, **variance**, **maximum**, **minimum**, **extrema**

Examples

```
>>> a = np.array([[1, 2, 0, 0],
...               [5, 3, 0, 4],
...               [0, 0, 0, 7],
...               [9, 3, 0, 0]])
>>> from scipy import ndimage
>>> ndimage.standard_deviation(a)
2.7585095613392387
```

Features to process can be specified using *labels* and *index*:

```
>>> lbl, nlbl = ndimage.label(a)
>>> ndimage.standard_deviation(a, lbl, index=np.arange(1, nlbl+1))
array([ 1.479,  1.5  ,  3.   ])
```

If no index is given, non-zero *labels* are processed:

```
>>> ndimage.standard_deviation(a, lbl)
2.4874685927665499
```

scipy.ndimage.sum_labels

scipy.ndimage.**sum_labels**(*input*, *labels=None*, *index=None*)

Calculate the sum of the values of the array.

Parameters

input [array_like] Values of *input* inside the regions defined by *labels* are summed together.

labels [array_like of ints, optional] Assign labels to the values of the array. Has to have the same shape as *input*.

index [array_like, optional] A single label number or a sequence of label numbers of the objects to be measured.

Returns

sum [ndarray or scalar] An array of the sums of values of *input* inside the regions defined by *labels* with the same shape as *index*. If 'index' is None or scalar, a scalar is returned.

See also:

mean, **median**

Examples

```
>>> from scipy import ndimage
>>> input =  [0,1,2,3]
>>> labels = [1,1,2,2]
>>> ndimage.sum(input, labels, index=[1,2])
[1.0, 5.0]
>>> ndimage.sum(input, labels, index=1)
1
```

(continues on next page)

(continued from previous page)

```
>>> ndimage.sum(input, labels)
6
```

scipy.ndimage.variance

scipy.ndimage.**variance**(*input*, *labels=None*, *index=None*)

Calculate the variance of the values of an N-D image array, optionally at specified sub-regions.

Parameters

input [array_like] Nd-image data to process.

labels [array_like, optional] Labels defining sub-regions in *input*. If not None, must be same shape as *input*.

index [int or sequence of ints, optional] *labels* to include in output. If None (default), all values where *labels* is non-zero are used.

Returns

variance [float or ndarray] Values of variance, for each sub-region if *labels* and *index* are specified.

See also:

label, **standard_deviation**, **maximum**, **minimum**, **extrema**

Examples

```
>>> a = np.array([[1, 2, 0, 0],
...               [5, 3, 0, 4],
...               [0, 0, 0, 7],
...               [9, 3, 0, 0]])
>>> from scipy import ndimage
>>> ndimage.variance(a)
7.609375
```

Features to process can be specified using *labels* and *index*:

```
>>> lbl, nlbl = ndimage.label(a)
>>> ndimage.variance(a, lbl, index=np.arange(1, nlbl+1))
array([ 2.1875,  2.25  ,  9.    ])
```

If no index is given, all non-zero *labels* are processed:

```
>>> ndimage.variance(a, lbl)
6.1875
```

scipy.ndimage.watershed_ift

scipy.ndimage.**watershed_ift**(*input*, *markers*, *structure=None*, *output=None*)

Apply watershed from markers using image foresting transform algorithm.

Parameters

input [array_like] Input.

markers [array_like] Markers are points within each watershed that form the beginning of the process. Negative markers are considered background markers which are processed after the other markers.

structure [structure element, optional] A structuring element defining the connectivity of the object can be provided. If None, an element is generated with a squared connectivity equal to one.

output [ndarray, optional] An output array can optionally be provided. The same shape as input.

Returns

watershed_ift

[ndarray] Output. Same shape as *input*.

morphological_laplace(input[, size, …])	Multidimensional morphological laplace.
white_tophat(input[, size, footprint, …])	Multidimensional white tophat filter.

scipy.ndimage.binary_closing

scipy.ndimage.**binary_closing**(*input*, *structure=None*, *iterations=1*, *output=None*, *origin=0*, *mask=None*, *border_value=0*, *brute_force=False*)

Multidimensional binary closing with the given structuring element.

The *closing* of an input image by a structuring element is the *erosion* of the *dilation* of the image by the structuring element.

Parameters

input [array_like] Binary array_like to be closed. Non-zero (True) elements form the subset to be closed.

structure [array_like, optional] Structuring element used for the closing. Non-zero elements are considered True. If no structuring element is provided an element is generated with a square connectivity equal to one (i.e., only nearest neighbors are connected to the center, diagonally-connected elements are not considered neighbors).

iterations [int, optional] The dilation step of the closing, then the erosion step are each repeated *iterations* times (one, by default). If iterations is less than 1, each operations is repeated until the result does not change anymore. Only an integer of iterations is accepted.

output [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.

origin [int or tuple of ints, optional] Placement of the filter, by default 0.

mask [array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration.
New in version 1.1.0.

border_value
[int (cast to 0 or 1), optional] Value at the border in the output array.
New in version 1.1.0.

brute_force
[boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated in the current iteration; if true al pixels are considered as candidates for update, regardless of what happened in the previous iteration. False by default.
New in version 1.1.0.

Returns

binary_closing
[ndarray of bools] Closing of the input by the structuring element.

See also:

grey_closing, **binary_opening**, **binary_dilation**, **binary_erosion**

generate_binary_structure

Notes

Closing [1] is a mathematical morphology operation [2] that consists in the succession of a dilation and an erosion of the input with the same structuring element. Closing therefore fills holes smaller than the structuring element.

Together with *opening* (`binary_opening`), closing can be used for noise removal.

       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
```

scipy.ndimage.binary_dilation

scipy.ndimage.**binary_dilation**(*input*, *structure=None*, *iterations=1*, *mask=None*, *output=None*, *border_value=0*, *origin=0*, *brute_force=False*)

Multidimensional binary dilation with the given structuring element.

Parameters

input [array_like] Binary array_like to be dilated. Non-zero (True) elements form the subset to be dilated.

structure [array_like, optional] Structuring element used for the dilation. Non-zero elements are considered True. If no structuring element is provided an element is generated with a square connectivity equal to one.

iterations [int, optional] The dilation is repeated *iterations* times (one, by default). If iterations is less than 1, the dilation is repeated until the result does not change anymore. Only an integer of iterations is accepted.

mask [array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration.

output [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.

border_value [int (cast to 0 or 1), optional] Value at the border in the output array.

origin [int or tuple of ints, optional] Placement of the filter, by default 0.

brute_force [boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated (dilated) in the current iteration; if True all pixels are considered as candidates for dilation, regardless of what happened in the previous iteration. False by default.

Returns

binary_dilation [ndarray of bools] Dilation of the input by the structuring element.

See also:

grey_dilation, **binary_erosion**, **binary_closing**, **binary_opening**

generate_binary_structure

Notes

Dilation [1] is a mathematical morphology operation [2] that uses a structuring element for expanding the shapes in an image. The binary dilation of an image by a structuring element is the locus of the points covered by the structuring element, when its center lies within the non-zero points of the image.

scipy.ndimage.binary_erosion

scipy.ndimage.**binary_erosion**(*input*, *structure=None*, *iterations=1*, *mask=None*, *output=None*, *border_value=0*, *origin=0*, *brute_force=False*)

Multidimensional binary erosion with a given structuring element.

Binary erosion is a mathematical morphology operation used for image processing.

Parameters

input [array_like] Binary image to be eroded. Non-zero (True) elements form the subset to be eroded.

structure [array_like, optional] Structuring element used for the erosion. Non-zero elements are considered True. If no structuring element is provided, an element is generated with a square connectivity equal to one.

iterations [int, optional] The erosion is repeated *iterations* times (one, by default). If iterations is less than 1, the erosion is repeated until the result does not change anymore.

mask [array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration.

output [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.

border_value [int (cast to 0 or 1), optional] Value at the border in the output array.

origin [int or tuple of ints, optional] Placement of the filter, by default 0.

brute_force [boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated (eroded) in the current iteration; if True all pixels are considered as candidates for erosion, regardless of what happened in the previous iteration. False by default.

Returns

binary_erosion [ndarray of bools] Erosion of the input by the structuring element.

See also:

grey_erosion, **binary_dilation**, **binary_closing**, **binary_opening**

generate_binary_structure

Notes

Erosion [1] is a mathematical morphology operation [2] that uses a structuring element for shrinking the shapes in an image. The binary erosion of an image by a structuring element is the locus of the points where a superimposition of the structuring element centered on the point is entirely contained in the set of non-zero elements of the image.

```

scipy.ndimage.binary_fill_holes

scipy.ndimage.**binary_fill_holes**(*input*, *structure=None*, *output=None*, *origin=0*)

Fill the holes in binary objects.

Parameters

input	[array_like] N-D binary array with holes to be filled
structure	[array_like, optional] Structuring element used in the computation; large-size elements make computations faster but may miss holes separated from the background by thin regions. The default element (with a square connectivity equal to one) yields the intuitive result where all holes in the input have been filled.
output	[ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.
origin	[int, tuple of ints, optional] Position of the structuring element.

Returns

out	[ndarray] Transformation of the initial image *input* where holes have been filled.

See also:

binary_dilation, **binary_propagation**, **label**

Notes

The algorithm used in this function consists in invading the complementary of the shapes in *input* from the outer boundary of the image, using binary dilations. Holes are not connected to the boundary and are therefore not invaded. The result is the complementary subset of the invaded region.

Examples

```
>>> from scipy import ndimage
>>> a = np.zeros((5, 5), dtype=int)
>>> a[1:4, 1:4] = 1
>>> a[2,2] = 0
>>> a
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 0, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
>>> ndimage.binary_fill_holes(a).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
>>> # Too big structuring element
```

(continues on next page)

(continued from previous page)

```
>>> ndimage.binary_fill_holes(a, structure=np.ones((5,5))).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 0, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
```

scipy.ndimage.binary_hit_or_miss

scipy.ndimage.**binary_hit_or_miss**(*input*, *structure1=None*, *structure2=None*, *output=None*, *origin1=0*, *origin2=None*)

Multidimensional binary hit-or-miss transform.

The hit-or-miss transform finds the locations of a given pattern inside the input image.

Parameters

input [array_like (cast to booleans)] Binary image where a pattern is to be detected.

structure1 [array_like (cast to booleans), optional] Part of the structuring element to be fitted to the foreground (non-zero elements) of *input*. If no value is provided, a structure of square connectivity 1 is chosen.

structure2 [array_like (cast to booleans), optional] Second part of the structuring element that has to miss completely the foreground. If no value is provided, the complementary of *structure1* is taken.

output [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.

origin1 [int or tuple of ints, optional] Placement of the first part of the structuring element *structure1*, by default 0 for a centered structure.

origin2 [int or tuple of ints, optional] Placement of the second part of the structuring element *structure2*, by default 0 for a centered structure. If a value is provided for *origin1* and not for *origin2*, then *origin2* is set to *origin1*.

Returns

binary_hit_or_miss

[ndarray] Hit-or-miss transform of *input* with the given structuring element (*structure1*, *structure2*).

       [0, 0, 0, 0, 0, 0, 0]])
```

scipy.ndimage.binary_opening

scipy.ndimage.**binary_opening**(*input*, *structure=None*, *iterations=1*, *output=None*, *origin=0*, *mask=None*, *border_value=0*, *brute_force=False*)

Multidimensional binary opening with the given structuring element.

The *opening* of an input image by a structuring element is the *dilation* of the *erosion* of the image by the structuring element.

Parameters

input [array_like] Binary array_like to be opened. Non-zero (True) elements form the subset to be opened.

structure [array_like, optional] Structuring element used for the opening. Non-zero elements are considered True. If no structuring element is provided an element is generated with a square

connectivity equal to one (i.e., only nearest neighbors are connected to the center, diagonally-connected elements are not considered neighbors).

iterations [int, optional] The erosion step of the opening, then the dilation step are each repeated *iterations* times (one, by default). If *iterations* is less than 1, each operation is repeated until the result does not change anymore. Only an integer of iterations is accepted.

output [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.

origin [int or tuple of ints, optional] Placement of the filter, by default 0.

mask [array_like, optional] If a mask is given, only those elements with a True value at the corresponding mask element are modified at each iteration.
New in version 1.1.0.

border_value
[int (cast to 0 or 1), optional] Value at the border in the output array.
New in version 1.1.0.

brute_force
[boolean, optional] Memory condition: if False, only the pixels whose value was changed in the last iteration are tracked as candidates to be updated in the current iteration; if true all pixels are considered as candidates for update, regardless of what happened in the previous iteration. False by default.
New in version 1.1.0.

Returns

binary_opening
[ndarray of bools] Opening of the input by the structuring element.

See also:

grey_opening, **binary_closing**, **binary_erosion**, **binary_dilation**

generate_binary_structure

Notes

Opening [1] is a mathematical morphology operation [2] that consists in the succession of an erosion and a dilation of the input with the same structuring element. Opening, therefore, removes objects smaller than the structuring element.

Together with *closing* (*binary_closing*), opening can be used for noise removal.

```
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 1]])
>>> # Opening removes small objects
>>> ndimage.binary_opening(a, structure=np.ones((3,3))).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 0, 0, 0]])
>>> # Opening can also smooth corners
>>> ndimage.binary_opening(a).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0]])
>>> # Opening is the dilation of the erosion of the input
>>> ndimage.binary_erosion(a).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0]])
>>> ndimage.binary_dilation(ndimage.binary_erosion(a)).astype(int)
array([[0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0],
       [0, 1, 1, 1, 0],
       [0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0]])
```

scipy.ndimage.binary_propagation

scipy.ndimage.**binary_propagation**(*input*, *structure=None*, *mask=None*, *output=None*, *border_value=0*, *origin=0*)

Multidimensional binary propagation with the given structuring element.

Parameters

input [array_like] Binary image to be propagated inside *mask*.

structure [array_like, optional] Structuring element used in the successive dilations. The output may depend on the structuring element, especially if *mask* has several connex components. If no structuring element is provided, an element is generated with a squared connectivity equal to one.

mask [array_like, optional] Binary mask defining the region into which *input* is allowed to propagate.

output [ndarray, optional] Array of the same shape as input, into which the output is placed. By default, a new array is created.

border_value [int (cast to 0 or 1), optional] Value at the border in the output array.

origin [int or tuple of ints, optional] Placement of the filter, by default 0.

Returns

binary_propagation [ndarray] Binary propagation of *input* inside *mask*.

Notes

This function is functionally equivalent to calling binary_dilation with the number of iterations less than one: iterative dilation until the result does not change anymore.

The succession of an erosion and propagation inside the original image can be used instead of an *opening* for deleting small objects while keeping the contours of larger objects untouched.

```

scipy.ndimage.black_tophat

scipy.ndimage.**black_tophat**(*input*, *size=None*, *footprint=None*, *structure=None*, *output=None*, *mode='reflect'*, *cval=0.0*, *origin=0*)

Multidimensional black tophat filter.

Parameters

input	[array_like] Input.
size	[tuple of ints, optional] Shape of a flat and full structuring element used for the filter. Optional if *footprint* or *structure* is provided.
footprint	[array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the black tophat filter.
structure	[array of ints, optional] Structuring element used for the filter. *structure* may be a non-flat structuring element.
output	[array, optional] An array used for storing the output of the filter may be provided.

mode [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The *mode* parameter determines how the array borders are handled, where *cval* is the value when mode is equal to 'constant'. Default is 'reflect'

cval [scalar, optional] Value to fill past edges of input if *mode* is 'constant'. Default is 0.0.

origin [scalar, optional] The *origin* parameter controls the placement of the filter. Default 0

Returns

black_tophat
[ndarray] Result of the filter of *input* with *structure*.

Examples

Change dark peak to bright peak and subtract background.

```
>>> from scipy.ndimage import generate_binary_structure, black_tophat
>>> square = generate_binary_structure(rank=2, connectivity=3)
>>> dark_on_gray = np.array([[7, 6, 6, 6, 7],
...                          [6, 5, 4, 5, 6],
...                          [6, 4, 0, 4, 6],
...                          [6, 5, 4, 5, 6],
...                          [7, 6, 6, 6, 7]])
>>> black_tophat(input=dark_on_gray, structure=square)
array([[0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0],
       [0, 1, 5, 1, 0],
       [0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0]])
```

scipy.ndimage.distance_transform_bf

scipy.ndimage.**distance_transform_bf**(*input*, *metric='euclidean'*, *sampling=None*, *return_distances=True*, *return_indices=False*, *distances=None*, *indices=None*)

Distance transform function by a brute force algorithm.

This function calculates the distance transform of the *input*, by replacing each foreground (non-zero) element, with its shortest distance to the background (any zero-valued element).

In addition to the distance transform, the feature transform can be calculated. In this case the index of the closest background element to each foreground element is returned in a separate array.

Parameters

input [array_like] Input

metric [{'euclidean', 'taxicab', 'chessboard'}, optional] 'cityblock' and 'manhattan' are also valid, and map to 'taxicab'. The default is 'euclidean'.

sampling [float, or sequence of float, optional] This parameter is only used when *metric* is 'euclidean'. Spacing of elements along each dimension. If a sequence, must be of length equal to the input rank; if a single number, this is used for all axes. If not specified, a grid spacing of unity is implied.

return_distances
[bool, optional] Whether to calculate the distance transform. Default is True.

return_indices
: [bool, optional] Whether to calculate the feature transform. Default is False.

distances
: [ndarray, optional] An output array to store the calculated distance transform, instead of returning it. *return_distances* must be True. It must be the same shape as *input*, and of type float64 if *metric* is 'euclidean', uint32 otherwise.

indices
: [int32 ndarray, optional] An output array to store the calculated feature transform, instead of returning it. *return_indicies* must be True. Its shape must be *(input.ndim,) + input.shape*.

Returns

distances
: [ndarray, optional] The calculated distance transform. Returned only when *return_distances* is True and *distances* is not supplied. It will have the same shape as the input array.

indices
: [int32 ndarray, optional] The calculated feature transform. It has an input-shaped array for each dimension of the input. See distance_transform_edt documentation for an example. Returned only when *return_indices* is True and *indices* is not supplied.

Notes

This function employs a slow brute force algorithm, see also the function distance_transform_cdt for more efficient taxicab and chessboard algorithms.

scipy.ndimage.distance_transform_cdt

scipy.ndimage.**distance_transform_cdt**(*input*, *metric='chessboard'*, *return_distances=True*, *return_indices=False*, *distances=None*, *indices=None*)

Distance transform for chamfer type of transforms.

In addition to the distance transform, the feature transform can be calculated. In this case the index of the closest background element to each foreground element is returned in a separate array.

Parameters

input
: [array_like] Input

metric
: [{'chessboard', 'taxicab'} or array_like, optional] The *metric* determines the type of chamfering that is done. If the *metric* is equal to 'taxicab' a structure is generated using generate_binary_structure with a squared distance equal to 1. If the *metric* is equal to 'chessboard', a *metric* is generated using generate_binary_structure with a squared distance equal to the dimensionality of the array. These choices correspond to the common interpretations of the 'taxicab' and the 'chessboard' distance metrics in two dimensions. A custom metric may be provided, in the form of a matrix where each dimension has a length of three. 'cityblock' and 'manhattan' are also valid, and map to 'taxicab'. The default is 'chessboard'.

return_distances
: [bool, optional] Whether to calculate the distance transform. Default is True.

return_indices
: [bool, optional] Whether to calculate the feature transform. Default is False.

distances
: [int32 ndarray, optional] An output array to store the calculated distance transform, instead of returning it. *return_distances* must be True. It must be the same shape as *input*.

indices
: [int32 ndarray, optional] An output array to store the calculated feature transform, instead of returning it. *return_indicies* must be True. Its shape must be *(input.ndim,) + input.shape*.

Returns

distances
: [int32 ndarray, optional] The calculated distance transform. Returned only when *return_distances* is True, and *distances* is not supplied. It will have the same shape as the input array.

indices [int32 ndarray, optional] The calculated feature transform. It has an input-shaped array for each dimension of the input. See distance_transform_edt documentation for an example. Returned only when *return_indices* is True, and *indices* is not supplied.

scipy.ndimage.distance_transform_edt

scipy.ndimage.**distance_transform_edt**(*input*, *sampling=None*, *return_distances=True*, *return_indices=False*, *distances=None*, *indices=None*)

Exact Euclidean distance transform.

In addition to the distance transform, the feature transform can be calculated. In this case the index of the closest background element to each foreground element is returned in a separate array.

Parameters

input [array_like] Input data to transform. Can be any type but will be converted into binary: 1 wherever input equates to True, 0 elsewhere.

sampling [float, or sequence of float, optional] Spacing of elements along each dimension. If a sequence, must be of length equal to the input rank; if a single number, this is used for all axes. If not specified, a grid spacing of unity is implied.

return_distances [bool, optional] Whether to calculate the distance transform. Default is True.

return_indices [bool, optional] Whether to calculate the feature transform. Default is False.

distances [float64 ndarray, optional] An output array to store the calculated distance transform, instead of returning it. *return_distances* must be True. It must be the same shape as *input*.

indices [int32 ndarray, optional] An output array to store the calculated feature transform, instead of returning it. *return_indicies* must be True. Its shape must be *(input.ndim,) + input.shape*.

Returns

distances [float64 ndarray, optional] The calculated distance transform. Returned only when *return_distances* is True and *distances* is not supplied. It will have the same shape as the input array.

indices [int32 ndarray, optional] The calculated feature transform. It has an input-shaped array for each dimension of the input. See example below. Returned only when *return_indices* is True and *indices* is not supplied.

Notes

The Euclidean distance transform gives values of the Euclidean distance:

```
                n
y_i = sqrt(sum (x[i]-b[i])**2)
                i
```

where b[i] is the background point (value 0) with the smallest Euclidean distance to input points x[i], and n is the number of dimensions.

Examples

```
>>> from scipy import ndimage
>>> a = np.array(([0,1,1,1,1],
...               [0,0,1,1,1],
...               [0,1,1,1,1],
...               [0,1,1,1,0],
...               [0,1,1,0,0]))
>>> ndimage.distance_transform_edt(a)
array([[ 0.    ,  1.    ,  1.4142,  2.2361,  3.    ],
       [ 0.    ,  0.    ,  1.    ,  2.    ,  2.    ],
       [ 0.    ,  1.    ,  1.4142,  1.4142,  1.    ],
       [ 0.    ,  1.    ,  1.4142,  1.    ,  0.    ],
       [ 0.    ,  1.    ,  1.    ,  0.    ,  0.    ]])
```

With a sampling of 2 units along x, 1 along y:

```
>>> ndimage.distance_transform_edt(a, sampling=[2,1])
array([[ 0.    ,  1.    ,  2.    ,  2.8284,  3.6056],
       [ 0.    ,  0.    ,  1.    ,  2.    ,  3.    ],
       [ 0.    ,  1.    ,  2.    ,  2.2361,  2.    ],
       [ 0.    ,  1.    ,  2.    ,  1.    ,  0.    ],
       [ 0.    ,  1.    ,  1.    ,  0.    ,  0.    ]])
```

Asking for indices as well:

```
>>> edt, inds = ndimage.distance_transform_edt(a, return_indices=True)
>>> inds
array([[[0, 0, 1, 1, 3],
        [1, 1, 1, 1, 3],
        [2, 2, 1, 3, 3],
        [3, 3, 4, 4, 3],
        [4, 4, 4, 4, 4]],
       [[0, 0, 1, 1, 4],
        [0, 1, 1, 1, 4],
        [0, 0, 1, 4, 4],
        [0, 0, 3, 3, 4],
        [0, 0, 3, 3, 4]]])
```

With arrays provided for inplace outputs:

```
>>> indices = np.zeros(((np.ndim(a),) + a.shape), dtype=np.int32)
>>> ndimage.distance_transform_edt(a, return_indices=True,␣
↪indices=indices)
array([[ 0.    ,  1.    ,  1.4142,  2.2361,  3.    ],
       [ 0.    ,  0.    ,  1.    ,  2.    ,  2.    ],
       [ 0.    ,  1.    ,  1.4142,  1.4142,  1.    ],
       [ 0.    ,  1.    ,  1.4142,  1.    ,  0.    ],
       [ 0.    ,  1.    ,  1.    ,  0.    ,  0.    ]])
>>> indices
array([[[0, 0, 1, 1, 3],
        [1, 1, 1, 1, 3],
        [2, 2, 1, 3, 3],
```

(continues on next page)

(continued from previous page)

```
         [3, 3, 4, 4, 3],
         [4, 4, 4, 4, 4]],
        [[0, 0, 1, 1, 4],
         [0, 1, 1, 1, 4],
         [0, 0, 1, 4, 4],
         [0, 0, 3, 3, 4],
         [0, 0, 3, 3, 4]]])
```

scipy.ndimage.generate_binary_structure

scipy.ndimage.**generate_binary_structure**(*rank*, *connectivity*)

Generate a binary structure for binary morphological operations.

Parameters

rank [int] Number of dimensions of the array to which the structuring element will be applied, as returned by *np.ndim*.

connectivity [int] *connectivity* determines which elements of the output array belong to the structure, i.e., are considered as neighbors of the central element. Elements up to a squared distance of *connectivity* from the center are considered neighbors. *connectivity* may range from 1 (no diagonal elements are neighbors) to *rank* (all elements are neighbors).

Returns

output [ndarray of bools] Structuring element which may be used for binary morphological operations, with *rank* dimensions and all dimensions equal to 3.

See also:

iterate_structure, **binary_dilation**, **binary_erosion**

Notes

generate_binary_structure can only create structuring elements with dimensions equal to 3, i.e., minimal dimensions. For larger structuring elements, that are useful e.g., for eroding large objects, one may either use *iterate_structure*, or create directly custom arrays with numpy functions such as numpy.ones.

Examples

```
>>> from scipy import ndimage
>>> struct = ndimage.generate_binary_structure(2, 1)
>>> struct
array([[False,  True, False],
       [ True,  True,  True],
       [False,  True, False]], dtype=bool)
>>> a = np.zeros((5,5))
>>> a[2, 2] = 1
>>> a
array([[ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.],
```

(continues on next page)

(continued from previous page)

```
       [ 0.,  0.,  0.,  0.,  0.]])
>>> b = ndimage.binary_dilation(a, structure=struct).astype(a.dtype)
>>> b
array([[ 0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  1.,  1.,  1.,  0.],
       [ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  0.,  0.,  0.,  0.]])
>>> ndimage.binary_dilation(b, structure=struct).astype(a.dtype)
array([[ 0.,  0.,  1.,  0.,  0.],
       [ 0.,  1.,  1.,  1.,  0.],
       [ 1.,  1.,  1.,  1.,  1.],
       [ 0.,  1.,  1.,  1.,  0.],
       [ 0.,  0.,  1.,  0.,  0.]])
>>> struct = ndimage.generate_binary_structure(2, 2)
>>> struct
array([[ True,  True,  True],
       [ True,  True,  True],
       [ True,  True,  True]], dtype=bool)
>>> struct = ndimage.generate_binary_structure(3, 1)
>>> struct # no diagonal elements
array([[[False, False, False],
        [False,  True, False],
        [False, False, False]],
       [[False,  True, False],
        [ True,  True,  True],
        [False,  True, False]],
       [[False, False, False],
        [False,  True, False],
        [False, False, False]]], dtype=bool)
```

scipy.ndimage.grey_closing

scipy.ndimage.**grey_closing**(*input*, *size=None*, *footprint=None*, *structure=None*, *output=None*, *mode='reflect'*, *cval=0.0*, *origin=0*)

Multidimensional grayscale closing.

A grayscale closing consists in the succession of a grayscale dilation, and a grayscale erosion.

Parameters

input	[array_like] Array over which the grayscale closing is to be computed.
size	[tuple of ints] Shape of a flat and full structuring element used for the grayscale closing. Optional if *footprint* or *structure* is provided.
footprint	[array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the grayscale closing.
structure	[array of ints, optional] Structuring element used for the grayscale closing. *structure* may be a non-flat structuring element.
output	[array, optional] An array used for storing the output of the closing may be provided.
mode	[{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The *mode* parameter determines how the array borders are handled, where *cval* is the value when mode is equal to 'constant'. Default is 'reflect'
cval	[scalar, optional] Value to fill past edges of input if *mode* is 'constant'. Default is 0.0.
origin	[scalar, optional] The *origin* parameter controls the placement of the filter. Default 0

Returns

grey_closing
[ndarray] Result of the grayscale closing of *input* with *structure*.

See also:

binary_closing, **grey_dilation**, **grey_erosion**, **grey_opening**

generate_binary_structure

Notes

The action of a grayscale closing with a flat structuring element amounts to smoothen deep local minima, whereas binary closing fills small holes.

Examples

```
>>> from scipy import ndimage
>>> a = np.arange(36).reshape((6,6))
>>> a[3,3] = 0
>>> a
array([[ 0,  1,  2,  3,  4,  5],
       [ 6,  7,  8,  9, 10, 11],
       [12, 13, 14, 15, 16, 17],
       [18, 19, 20,  0, 22, 23],
       [24, 25, 26, 27, 28, 29],
       [30, 31, 32, 33, 34, 35]])
>>> ndimage.grey_closing(a, size=(3,3))
array([[ 7,  7,  8,  9, 10, 11],
       [ 7,  7,  8,  9, 10, 11],
       [13, 13, 14, 15, 16, 17],
       [19, 19, 20, 20, 22, 23],
       [25, 25, 26, 27, 28, 29],
       [31, 31, 32, 33, 34, 35]])
>>> # Note that the local minimum a[3,3] has disappeared
```

scipy.ndimage.grey_dilation

scipy.ndimage.**grey_dilation**(*input*, *size=None*, *footprint=None*, *structure=None*, *output=None*, *mode='reflect'*, *cval=0.0*, *origin=0*)

Calculate a greyscale dilation, using either a structuring element, or a footprint corresponding to a flat structuring element.

Grayscale dilation is a mathematical morphology operation. For the simple case of a full and flat structuring element, it can be viewed as a maximum filter over a sliding window.

Parameters

input [array_like] Array over which the grayscale dilation is to be computed.

size [tuple of ints] Shape of a flat and full structuring element used for the grayscale dilation. Optional if *footprint* or *structure* is provided.

footprint [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the grayscale dilation. Non-zero values give the set of neighbors of the center over which the maximum is chosen.

structure [array of ints, optional] Structuring element used for the grayscale dilation. *structure* may be a non-flat structuring element.

output [array, optional] An array used for storing the output of the dilation may be provided.

mode [{'reflect','constant','nearest','mirror', 'wrap'}, optional] The *mode* parameter determines how the array borders are handled, where *cval* is the value when mode is equal to 'constant'. Default is 'reflect'

cval [scalar, optional] Value to fill past edges of input if *mode* is 'constant'. Default is 0.0.

origin [scalar, optional] The *origin* parameter controls the placement of the filter. Default 0

Returns

grey_dilation
[ndarray] Grayscale dilation of *input*.

See also:

binary_dilation, **grey_erosion**, **grey_closing**, **grey_opening**

generate_binary_structure, **maximum_filter**

Notes

The grayscale dilation of an image input by a structuring element s defined over a domain E is given by:

(input+s)(x) = max {input(y) + s(x-y), for y in E}

In particular, for structuring elements defined as s(y) = 0 for y in E, the grayscale dilation computes the maximum of the input image inside a sliding window defined by E.

Grayscale dilation [1] is a *mathematical morphology* operation [2].

       [0, 0, 1, 1, 2, 0, 0],
       [0, 0, 0, 0, 0, 0, 0]])
>>> ndimage.grey_dilation(a, size=(3,3), structure=np.ones((3,3)))
array([[1, 1, 1, 1, 1, 1, 1],
       [1, 2, 4, 4, 4, 2, 1],
       [1, 2, 4, 4, 4, 2, 1],
       [1, 2, 4, 4, 4, 3, 1],
       [1, 2, 2, 3, 3, 3, 1],
       [1, 2, 2, 3, 3, 3, 1],
       [1, 1, 1, 1, 1, 1, 1]])
```

scipy.ndimage.grey_erosion

scipy.ndimage.**grey_erosion**(*input*, *size=None*, *footprint=None*, *structure=None*, *output=None*, *mode='reflect'*, *cval=0.0*, *origin=0*)

Calculate a greyscale erosion, using either a structuring element, or a footprint corresponding to a flat structuring element.

Grayscale erosion is a mathematical morphology operation. For the simple case of a full and flat structuring element, it can be viewed as a minimum filter over a sliding window.

Parameters

input [array_like] Array over which the grayscale erosion is to be computed.

size [tuple of ints] Shape of a flat and full structuring element used for the grayscale erosion. Optional if *footprint* or *structure* is provided.

footprint [array of ints, optional] Positions of non-infinite elements of a flat structuring element used

for the grayscale erosion. Non-zero values give the set of neighbors of the center over which the minimum is chosen.

structure [array of ints, optional] Structuring element used for the grayscale erosion. *structure* may be a non-flat structuring element.

output [array, optional] An array used for storing the output of the erosion may be provided.

mode [{'reflect','constant','nearest','mirror', 'wrap'}, optional] The *mode* parameter determines how the array borders are handled, where *cval* is the value when mode is equal to 'constant'. Default is 'reflect'

cval [scalar, optional] Value to fill past edges of input if *mode* is 'constant'. Default is 0.0.

origin [scalar, optional] The *origin* parameter controls the placement of the filter. Default 0

Returns

output [ndarray] Grayscale erosion of *input*.

See also:

binary_erosion, **grey_dilation**, **grey_opening**, **grey_closing**

generate_binary_structure, **minimum_filter**

Notes

The grayscale erosion of an image input by a structuring element s defined over a domain E is given by:

(input+s)(x) = min {input(y) - s(x-y), for y in E}

In particular, for structuring elements defined as s(y) = 0 for y in E, the grayscale erosion computes the minimum of the input image inside a sliding window defined by E.

Grayscale erosion [1] is a *mathematical morphology* operation [2].

       [0, 0, 0, 0, 0, 0, 0]])
```

scipy.ndimage.grey_opening

scipy.ndimage.**grey_opening**(*input*, *size=None*, *footprint=None*, *structure=None*, *output=None*, *mode='reflect'*, *cval=0.0*, *origin=0*)

Multidimensional grayscale opening.

A grayscale opening consists in the succession of a grayscale erosion, and a grayscale dilation.

Parameters

input [array_like] Array over which the grayscale opening is to be computed.

size [tuple of ints] Shape of a flat and full structuring element used for the grayscale opening. Optional if *footprint* or *structure* is provided.

footprint [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the grayscale opening.

structure [array of ints, optional] Structuring element used for the grayscale opening. *structure* may be a non-flat structuring element.

output [array, optional] An array used for storing the output of the opening may be provided.

mode [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The *mode* parameter determines how the array borders are handled, where *cval* is the value when mode is equal to 'constant'. Default is 'reflect'

cval [scalar, optional] Value to fill past edges of input if *mode* is 'constant'. Default is 0.0.

origin [scalar, optional] The *origin* parameter controls the placement of the filter. Default 0

Returns

grey_opening
[ndarray] Result of the grayscale opening of *input* with *structure*.

See also:

binary_opening, **grey_dilation**, **grey_erosion**, **grey_closing**

generate_binary_structure

Notes

The action of a grayscale opening with a flat structuring element amounts to smoothen high local maxima, whereas binary opening erases small objects.

```
>>> from scipy import ndimage
>>> a = np.arange(36).reshape((6,6))
>>> a[3, 3] = 50
>>> a
array([[ 0,  1,  2,  3,  4,  5],
       [ 6,  7,  8,  9, 10, 11],
       [12, 13, 14, 15, 16, 17],
       [18, 19, 20, 50, 22, 23],
       [24, 25, 26, 27, 28, 29],
       [30, 31, 32, 33, 34, 35]])
>>> ndimage.grey_opening(a, size=(3,3))
array([[ 0,  1,  2,  3,  4,  4],
       [ 6,  7,  8,  9, 10, 10],
       [12, 13, 14, 15, 16, 16],
       [18, 19, 20, 22, 22, 22],
       [24, 25, 26, 27, 28, 28],
       [24, 25, 26, 27, 28, 28]])
>>> # Note that the local maximum a[3,3] has disappeared
```

scipy.ndimage.iterate_structure

scipy.ndimage.**iterate_structure**(*structure*, *iterations*, *origin=None*)

Iterate a structure by dilating it with itself.

Parameters

structure [array_like] Structuring element (an array of bools, for example), to be dilated with itself.

iterations [int] number of dilations performed on the structure with itself

origin [optional] If origin is None, only the iterated structure is returned. If not, a tuple of the iterated structure and the modified origin is returned.

Returns

iterate_structure

[ndarray of bools] A new structuring element obtained by dilating *structure* (*iterations* - 1) times with itself.

See also:

generate_binary_structure

Examples

```
>>> from scipy import ndimage
>>> struct = ndimage.generate_binary_structure(2, 1)
>>> struct.astype(int)
array([[0, 1, 0],
       [1, 1, 1],
       [0, 1, 0]])
>>> ndimage.iterate_structure(struct, 2).astype(int)
array([[0, 0, 1, 0, 0],
       [0, 1, 1, 1, 0],
       [1, 1, 1, 1, 1],
       [0, 1, 1, 1, 0],
       [0, 0, 1, 0, 0]])
>>> ndimage.iterate_structure(struct, 3).astype(int)
array([[0, 0, 0, 1, 0, 0, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 1, 1, 1, 1, 1, 0],
       [1, 1, 1, 1, 1, 1, 1],
       [0, 1, 1, 1, 1, 1, 0],
       [0, 0, 1, 1, 1, 0, 0],
       [0, 0, 0, 1, 0, 0, 0]])
```

scipy.ndimage.morphological_gradient

scipy.ndimage.**morphological_gradient**(*input*, *size=None*, *footprint=None*, *structure=None*, *output=None*, *mode='reflect'*, *cval=0.0*, *origin=0*)

Multidimensional morphological gradient.

The morphological gradient is calculated as the difference between a dilation and an erosion of the input with a given structuring element.

Parameters

input [array_like] Array over which to compute the morphlogical gradient.

size [tuple of ints] Shape of a flat and full structuring element used for the mathematical morphology operations. Optional if *footprint* or *structure* is provided. A larger *size* yields a more blurred gradient.

footprint [array of ints, optional] Positions of non-infinite elements of a flat structuring element used for the morphology operations. Larger footprints give a more blurred morphological gradient.

structure [array of ints, optional] Structuring element used for the morphology operations. *structure* may be a non-flat structuring element.

output [array, optional] An array used for storing the output of the morphological gradient may be provided.

mode [{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The *mode* parameter determines how the array borders are handled, where *cval* is the value when mode is equal to 'constant'. Default is 'reflect'

cval [scalar, optional] Value to fill past edges of input if *mode* is 'constant'. Default is 0.0.

origin [scalar, optional] The *origin* parameter controls the placement of the filter. Default 0

Returns

morphological_gradient
[ndarray] Morphological gradient of *input*.

See also:

grey_dilation, **grey_erosion**, **gaussian_gradient_magnitude**

Notes

For a flat structuring element, the morphological gradient computed at a given point corresponds to the maximal difference between elements of the input among the elements covered by the structuring element centered on the point.

       [0, 0, 0, 0, 0, 0, 0]])
```

scipy.ndimage.morphological_laplace

scipy.ndimage.**morphological_laplace**(*input*, *size=None*, *footprint=None*, *structure=None*, *output=None*, *mode='reflect'*, *cval=0.0*, *origin=0*)

Multidimensional morphological laplace.

Parameters

input	[array_like] Input.
size	[int or sequence of ints, optional] See *structure*.
footprint	[bool or ndarray, optional] See *structure*.
structure	[structure, optional] Either *size*, *footprint*, or the *structure* must be provided.
output	[ndarray, optional] An output array can optionally be provided.
mode	[{'reflect','constant','nearest','mirror', 'wrap'}, optional] The mode parameter determines how the array borders are handled. For 'constant' mode, values beyond borders are set to be *cval*. Default is 'reflect'.
cval	[scalar, optional] Value to fill past edges of input if mode is 'constant'. Default is 0.0
origin	[origin, optional] The origin parameter controls the placement of the filter.

Returns

morphological_laplace
: [ndarray] Output

scipy.ndimage.white_tophat

scipy.ndimage.**white_tophat**(*input*, *size=None*, *footprint=None*, *structure=None*, *output=None*, *mode='reflect'*, *cval=0.0*, *origin=0*)

Multidimensional white tophat filter.

Parameters

input	[array_like] Input.
size	[tuple of ints] Shape of a flat and full structuring element used for the filter. Optional if *footprint* or *structure* is provided.
footprint	[array of ints, optional] Positions of elements of a flat structuring element used for the white tophat filter.
structure	[array of ints, optional] Structuring element used for the filter. *structure* may be a non-flat structuring element.
output	[array, optional] An array used for storing the output of the filter may be provided.
mode	[{'reflect', 'constant', 'nearest', 'mirror', 'wrap'}, optional] The *mode* parameter determines how the array borders are handled, where *cval* is the value when mode is equal to 'constant'. Default is 'reflect'
cval	[scalar, optional] Value to fill past edges of input if *mode* is 'constant'. Default is 0.0.
origin	[scalar, optional] The *origin* parameter controls the placement of the filter. Default is 0.

Returns

output	[ndarray] Result of the filter of *input* with *structure*.

black_tophat

Examples

Subtract gray background from a bright peak.

```
>>> from scipy.ndimage import generate_binary_structure, white_tophat
>>> square = generate_binary_structure(rank=2, connectivity=3)
>>> bright_on_gray = np.array([[2, 3, 3, 3, 2],
...                            [3, 4, 5, 4, 3],
...                            [3, 5, 9, 5, 3],
...                            [3, 4, 5, 4, 3],
...                            [2, 3, 3, 3, 2]])
>>> white_tophat(input=bright_on_gray, structure=square)
array([[0, 0, 0, 0, 0],
       [0, 0, 1, 0, 0],
       [0, 1, 5, 1, 0],
       [0, 0, 1, 0, 0],
       [0, 0, 0, 0, 0]])
```

3.3.18 Orthogonal distance regression (`scipy.odr`)

Package Content

Data(x[, y, we, wd, fix, meta])	The data to fit.
RealData(x[, y, sx, sy, covx, covy, fix, meta])	The data, with weightings as actual standard deviations and/or covariances.
Model(fcn[, fjacb, fjacd, extra_args, …])	The Model class stores information about the function you wish to fit.
ODR(data, model[, beta0, delta0, ifixb, …])	The ODR class gathers all information and coordinates the running of the main fitting routine.
Output(output)	The Output class stores the output of an ODR run.
odr(fcn, beta0, y, x[, we, wd, fjacb, …])	Low-level function for ODR.
OdrWarning	Warning indicating that the data passed into ODR will cause problems when passed into 'odr' that the user should be aware of.
OdrError	Exception indicating an error in fitting.
OdrStop	Exception stopping fitting.
polynomial(order)	Factory function for a general polynomial model.
exponential	Exponential model
multilinear	Arbitrary-dimensional linear model
unilinear	Univariate linear model
quadratic	Quadratic model

scipy.odr.Data

class scipy.odr.**Data**(*x*, *y=None*, *we=None*, *wd=None*, *fix=None*, *meta={}*)

The data to fit.

Parameters

x [array_like] Observed data for the independent variable of the regression

y [array_like, optional] If array-like, observed data for the dependent variable of the regression. A scalar input implies that the model to be used on the data is implicit.

we [array_like, optional] If *we* is a scalar, then that value is used for all data points (and all dimensions of the response variable). If *we* is a rank-1 array of length q (the dimensionality of the response variable), then this vector is the diagonal of the covariant weighting matrix for all data points. If *we* is a rank-1 array of length n (the number of data points), then the i'th element is the weight for the i'th response variable observation (single-dimensional only). If *we* is a rank-2 array of shape (q, q), then this is the full covariant weighting matrix broadcast to each observation. If *we* is a rank-2 array of shape (q, n), then *we[:,i]* is the diagonal of the covariant weighting matrix for the i'th observation. If *we* is a rank-3 array of shape (q, q, n), then *we[:,:,i]* is the full specification of the covariant weighting matrix for each observation. If the fit is implicit, then only a positive scalar value is used.

wd [array_like, optional] If *wd* is a scalar, then that value is used for all data points (and all dimensions of the input variable). If *wd* = 0, then the covariant weighting matrix for each observation is set to the identity matrix (so each dimension of each observation has the same weight). If *wd* is a rank-1 array of length m (the dimensionality of the input variable), then this vector is the diagonal of the covariant weighting matrix for all data points. If *wd* is a rank-1 array of length n (the number of data points), then the i'th element is the weight for the ith input variable observation (single-dimensional only). If *wd* is a rank-2 array of shape (m, m), then this is the full covariant weighting matrix broadcast to each observation. If *wd* is a rank-2 array of shape (m, n), then *wd[:,i]* is the diagonal of the covariant weighting matrix for the ith observation. If *wd* is a rank-3 array of shape (m, m, n), then *wd[:,:,i]* is the full specification of the covariant weighting matrix for each observation.

fix [array_like of ints, optional] The *fix* argument is the same as ifixx in the class ODR. It is an array of integers with the same shape as data.x that determines which input observations are treated as fixed. One can use a sequence of length m (the dimensionality of the input observations) to fix some dimensions for all observations. A value of 0 fixes the observation, a value > 0 makes it free.

meta [dict, optional] Free-form dictionary for metadata.

Notes

Each argument is attached to the member of the instance of the same name. The structures of *x* and *y* are described in the Model class docstring. If *y* is an integer, then the Data instance can only be used to fit with implicit models where the dimensionality of the response is equal to the specified value of *y*.

The *we* argument weights the effect a deviation in the response variable has on the fit. The *wd* argument weights the effect a deviation in the input variable has on the fit. To handle multidimensional inputs and responses easily, the structure of these arguments has the n'th dimensional axis first. These arguments heavily use the structured arguments feature of ODRPACK to conveniently and flexibly support all options. See the ODRPACK User's Guide for a full explanation of how these weights are used in the algorithm. Basically, a higher value of the weight for a particular data point makes a deviation at that point more detrimental to the fit.

Methods

set_meta(**kwds)	Update the metadata dictionary with the keywords and data provided by keywords.

scipy.odr.Data.set_meta

Data.**set_meta**(***kwds*)

Update the metadata dictionary with the keywords and data provided by keywords.

Examples

```
data.set_meta(lab="Ph 7; Lab 26", title="Ag110 + Ag108 Decay")
```

scipy.odr.RealData

class scipy.odr.**RealData**(*x*, *y=None*, *sx=None*, *sy=None*, *covx=None*, *covy=None*, *fix=None*, *meta={}*)

The data, with weightings as actual standard deviations and/or covariances.

Parameters

x	[array_like] Observed data for the independent variable of the regression
y	[array_like, optional] If array-like, observed data for the dependent variable of the regression. A scalar input implies that the model to be used on the data is implicit.
sx	[array_like, optional] Standard deviations of *x*. *sx* are standard deviations of *x* and are converted to weights by dividing 1.0 by their squares.
sy	[array_like, optional] Standard deviations of *y*. *sy* are standard deviations of *y* and are converted to weights by dividing 1.0 by their squares.
covx	[array_like, optional] Covariance of *x* *covx* is an array of covariance matrices of *x* and are converted to weights by performing a matrix inversion on each observation's covariance matrix.
covy	[array_like, optional] Covariance of *y* *covy* is an array of covariance matrices and are converted to weights by performing a matrix inversion on each observation's covariance matrix.
fix	[array_like, optional] The argument and member fix is the same as Data.fix and ODR.ifixx: It is an array of integers with the same shape as *x* that determines which input observations are treated as fixed. One can use a sequence of length m (the dimensionality of the input observations) to fix some dimensions for all observations. A value of 0 fixes the observation, a value > 0 makes it free.
meta	[dict, optional] Free-form dictionary for metadata.

Notes

The weights *wd* and *we* are computed from provided values as follows:

sx and *sy* are converted to weights by dividing 1.0 by their squares. For example, `wd = 1./numpy.power(`sx`, 2)`.

covx and *covy* are arrays of covariance matrices and are converted to weights by performing a matrix inversion on each observation's covariance matrix. For example, `we[i] = numpy.linalg.inv(covy[i])`.

These arguments follow the same structured argument conventions as wd and we only restricted by their natures: *sx* and *sy* can't be rank-3, but *covx* and *covy* can be.

Only set *either sx* or *covx* (not both). Setting both will raise an exception. Same with *sy* and *covy*.

Methods

set_meta(**kwds)	Update the metadata dictionary with the keywords and data provided by keywords.

scipy.odr.RealData.set_meta

RealData.**set_meta**(**kwds)
Update the metadata dictionary with the keywords and data provided by keywords.

Examples

```
data.set_meta(lab="Ph 7; Lab 26", title="Ag110 + Ag108 Decay")
```

scipy.odr.Model

class scipy.odr.**Model**(*fcn*, *fjacb=None*, *fjacd=None*, *extra_args=None*, *estimate=None*, *implicit=0*, *meta=None*)
The Model class stores information about the function you wish to fit.

It stores the function itself, at the least, and optionally stores functions which compute the Jacobians used during fitting. Also, one can provide a function that will provide reasonable starting values for the fit parameters possibly given the set of data.

Parameters

fcn	[function] fcn(beta, x) –> y
fjacb	[function] Jacobian of fcn wrt the fit parameters beta. fjacb(beta, x) –> @f_i(x,B)/@B_j
fjacd	[function] Jacobian of fcn wrt the (possibly multidimensional) input variable. fjacd(beta, x) –> @f_i(x,B)/@x_j
extra_args	[tuple, optional] If specified, *extra_args* should be a tuple of extra arguments to pass to *fcn*, *fjacb*, and *fjacd*. Each will be called by *apply(fcn, (beta, x) + extra_args)*
estimate	[array_like of rank-1] Provides estimates of the fit parameters from the data estimate(data) –> estbeta
implicit	[boolean] If TRUE, specifies that the model is implicit; i.e *fcn(beta, x)* ~= 0 and there is no y data to fit against
meta	[dict, optional] freeform dictionary of metadata for the model

Notes

Note that the *fcn*, *fjacb*, and *fjacd* operate on NumPy arrays and return a NumPy array. The *estimate* object takes an instance of the Data class.

Here are the rules for the shapes of the argument and return arrays of the callback functions:

x if the input data is single-dimensional, then *x* is rank-1 array; i.e., `x = array([1, 2, 3, ...]); x.shape = (n,)` If the input data is multi-dimensional, then *x* is a rank-2 array; i.e., `x = array([[1, 2, ...], [2, 4, ...]]); x.shape = (m, n)`. In all cases, it has the same shape as the input data array passed to *odr*. *m* is the dimensionality of the input data, *n* is the number of observations.

y if the response variable is single-dimensional, then *y* is a rank-1 array, i.e., `y = array([2, 4, ...]); y.shape = (n,)`. If the response variable is multi-dimensional, then *y* is a rank-2 array, i.e., `y = array([[2, 4, ...], [3, 6, ...]]); y.shape = (q, n)` where *q* is the dimensionality of the response variable.

beta

rank-1 array of length *p* where *p* is the number of parameters; i.e. `beta = array([B_1, B_2, ..., B_p])`

fjacb

if the response variable is multi-dimensional, then the return array's shape is *(q, p, n)* such that `fjacb(x, beta)[l,k,i] = d f_l(X,B)/d B_k` evaluated at the ith data point. If *q == 1*, then the return array is only rank-2 and with shape *(p, n)*.

fjacd

as with fjacb, only the return array's shape is *(q, m, n)* such that `fjacd(x,beta)[l,j,i] = d f_l(X, B)/d X_j` at the ith data point. If *q == 1*, then the return array's shape is *(m, n)*. If *m == 1*, the shape is (q, n). If *m == q == 1*, the shape is *(n,)*.

Methods

set_meta(**kwds)	Update the metadata dictionary with the keywords and data provided here.

scipy.odr.Model.set_meta

Model.**set_meta**(***kwds*)

Update the metadata dictionary with the keywords and data provided here.

Examples

set_meta(name="Exponential", equation="y = a exp(b x) + c")

scipy.odr.ODR

class scipy.odr.**ODR**(*data*, *model*, *beta0=None*, *delta0=None*, *ifixb=None*, *ifixx=None*, *job=None*, *iprint=None*, *errfile=None*, *rptfile=None*, *ndigit=None*, *taufac=None*, *sstol=None*, *partol=None*, *maxit=None*, *stpb=None*, *stpd=None*, *sclb=None*, *scld=None*, *work=None*, *iwork=None*, *overwrite=False*)

The ODR class gathers all information and coordinates the running of the main fitting routine.

Members of instances of the ODR class have the same names as the arguments to the initialization routine.

Parameters

data [Data class instance] instance of the Data class

model [Model class instance] instance of the Model class

Other Parameters

beta0 [array_like of rank-1] a rank-1 sequence of initial parameter values. Optional if model provides an "estimate" function to estimate these values.

delta0 [array_like of floats of rank-1, optional] a (double-precision) float array to hold the initial values of the errors in the input variables. Must be same shape as data.x

ifixb [array_like of ints of rank-1, optional] sequence of integers with the same length as beta0 that determines which parameters are held fixed. A value of 0 fixes the parameter, a value > 0 makes the parameter free.

ifixx [array_like of ints with same shape as data.x, optional] an array of integers with the same shape as data.x that determines which input observations are treated as fixed. One can use a sequence of length m (the dimensionality of the input observations) to fix some dimensions for all observations. A value of 0 fixes the observation, a value > 0 makes it free.

job [int, optional] an integer telling ODRPACK what tasks to perform. See p. 31 of the ODRPACK User's Guide if you absolutely must set the value here. Use the method set_job post-initialization for a more readable interface.

iprint [int, optional] an integer telling ODRPACK what to print. See pp. 33-34 of the ODRPACK User's Guide if you absolutely must set the value here. Use the method set_iprint post-initialization for a more readable interface.

errfile [str, optional] string with the filename to print ODRPACK errors to. If the file already exists, an error will be thrown. The *overwrite* argument can be used to prevent this. *Do Not Open This File Yourself!*

rptfile [str, optional] string with the filename to print ODRPACK summaries to. If the file already exists, an error will be thrown. The *overwrite* argument can be used to prevent this. *Do Not Open This File Yourself!*

ndigit [int, optional] integer specifying the number of reliable digits in the computation of the function.

taufac [float, optional] float specifying the initial trust region. The default value is 1. The initial trust region is equal to taufac times the length of the first computed Gauss-Newton step. taufac must be less than 1.

sstol [float, optional] float specifying the tolerance for convergence based on the relative change in the sum-of-squares. The default value is eps**(1/2) where eps is the smallest value such that 1 + eps > 1 for double precision computation on the machine. sstol must be less than 1.

partol [float, optional] float specifying the tolerance for convergence based on the relative change in the estimated parameters. The default value is eps**(2/3) for explicit models and `eps**(1/3)` for implicit models. partol must be less than 1.

maxit [int, optional] integer specifying the maximum number of iterations to perform. For first runs, maxit is the total number of iterations performed and defaults to 50. For restarts, maxit is the number of additional iterations to perform and defaults to 10.

stpb [array_like, optional] sequence (`len(stpb) == len(beta0)`) of relative step sizes to compute finite difference derivatives wrt the parameters.

stpd [optional] array (`stpd.shape == data.x.shape` or `stpd.shape == (m,)`) of relative step sizes to compute finite difference derivatives wrt the input variable errors. If stpd is a rank-1 array with length m (the dimensionality of the input variable), then the values are broadcast to all observations.

sclb [array_like, optional] sequence (`len(stpb) == len(beta0)`) of scaling factors for the parameters. The purpose of these scaling factors are to scale all of the parameters to around unity. Normally appropriate scaling factors are computed if this argument is not specified. Specify them yourself if the automatic procedure goes awry.

scld [array_like, optional] array (scld.shape == data.x.shape or scld.shape == (m,)) of scaling factors for the *errors* in the input variables. Again, these factors are automatically computed if you do not provide them. If scld.shape == (m,), then the scaling factors are broadcast to all observations.

work [ndarray, optional] array to hold the double-valued working data for ODRPACK. When restarting, takes the value of self.output.work.

iwork [ndarray, optional] array to hold the integer-valued working data for ODRPACK. When restarting, takes the value of self.output.iwork.

overwrite [bool, optional] If it is True, output files defined by *errfile* and *rptfile* are overwritten. The default is False.

Attributes

data [Data] The data for this fit
model [Model] The model used in fit
output [Output] An instance if the Output class containing all of the returned data from an invocation of ODR.run() or ODR.restart()

Methods

restart([iter])	Restarts the run with iter more iterations.
run()	Run the fitting routine with all of the information given and with `full_output=1`.
set_iprint([init, so_init, iter, so_iter, …])	Set the iprint parameter for the printing of computation reports.
set_job([fit_type, deriv, var_calc, …])	Sets the "job" parameter is a hopefully comprehensible way.

scipy.odr.ODR.restart

ODR.**restart**(*iter=None*)
Restarts the run with iter more iterations.

Parameters

iter [int, optional] ODRPACK's default for the number of new iterations is 10.

Returns

output [Output instance] This object is also assigned to the attribute .output .

scipy.odr.ODR.run

ODR.**run**()
Run the fitting routine with all of the information given and with `full_output=1`.

Returns

output [Output instance] This object is also assigned to the attribute .output .

scipy.odr.ODR.set_iprint

ODR.**set_iprint**(*init=None*, *so_init=None*, *iter=None*, *so_iter=None*, *iter_step=None*, *final=None*, *so_final=None*)
Set the iprint parameter for the printing of computation reports.

If any of the arguments are specified here, then they are set in the iprint member. If iprint is not set manually or with this method, then ODRPACK defaults to no printing. If no filename is specified with the member rptfile, then ODRPACK prints to stdout. One can tell ODRPACK to print to stdout in addition to the specified filename by setting the so_* arguments to this function, but one cannot specify to print to stdout but not a file since one can do that by not specifying a rptfile filename.

There are three reports: initialization, iteration, and final reports. They are represented by the arguments init, iter, and final respectively. The permissible values are 0, 1, and 2 representing “no report”, “short report”, and “long report” respectively.

The argument iter_step (0 <= iter_step <= 9) specifies how often to make the iteration report; the report will be made for every iter_step’th iteration starting with iteration one. If iter_step == 0, then no iteration report is made, regardless of the other arguments.

If the rptfile is None, then any so_* arguments supplied will raise an exception.

scipy.odr.ODR.set_job

ODR.**set_job**(*fit_type=None*, *deriv=None*, *var_calc=None*, *del_init=None*, *restart=None*)

Sets the “job” parameter is a hopefully comprehensible way.

If an argument is not specified, then the value is left as is. The default value from class initialization is for all of these options set to 0.

Parameters

fit_type [{0, 1, 2} int] 0 -> explicit ODR
1 -> implicit ODR
2 -> ordinary least-squares

deriv [{0, 1, 2, 3} int] 0 -> forward finite differences
1 -> central finite differences
2 -> user-supplied derivatives (Jacobians) with results checked by ODRPACK
3 -> user-supplied derivatives, no checking

var_calc [{0, 1, 2} int]
0 -> calculate asymptotic covariance matrix and fit parameter uncertainties (V_B, s_B) using derivatives recomputed at the final solution
1 -> calculate V_B and s_B using derivatives from last iteration
2 -> do not calculate V_B and s_B

del_init [{0, 1} int] 0 -> initial input variable offsets set to 0
1 -> initial offsets provided by user in variable “work”

restart [{0, 1} int] 0 -> fit is not a restart
1 -> fit is a restart

Notes

The permissible values are different from those given on pg. 31 of the ODRPACK User’s Guide only in that one cannot specify numbers greater than the last value for each variable.

If one does not supply functions to compute the Jacobians, the fitting procedure will change deriv to 0, finite differences, as a default. To initialize the input variable offsets by yourself, set del_init to 1 and put the offsets into the “work” variable correctly.

scipy.odr.Output

class scipy.odr.**Output**(*output*)

The Output class stores the output of an ODR run.

Notes

Takes one argument for initialization, the return value from the function *odr*. The attributes listed as "optional" above are only present if *odr* was run with `full_output=1`.

Attributes

beta [ndarray] Estimated parameter values, of shape (q,).
sd_beta [ndarray] Standard deviations of the estimated parameters, of shape (p,).
cov_beta [ndarray] Covariance matrix of the estimated parameters, of shape (p,p).
delta [ndarray, optional] Array of estimated errors in input variables, of same shape as *x*.
eps [ndarray, optional] Array of estimated errors in response variables, of same shape as *y*.
xplus [ndarray, optional] Array of `x + delta`.
y [ndarray, optional] Array `y = fcn(x + delta)`.
res_var [float, optional] Residual variance.
sum_square [float, optional] Sum of squares error.
sum_square_delta [float, optional] Sum of squares of delta error.
sum_square_eps [float, optional] Sum of squares of eps error.
inv_condnum [float, optional] Inverse condition number (cf. ODRPACK UG p. 77).
rel_error [float, optional] Relative error in function values computed within fcn.
work [ndarray, optional] Final work array.
work_ind [dict, optional] Indices into work for drawing out values (cf. ODRPACK UG p. 83).
info [int, optional] Reason for returning, as output by ODRPACK (cf. ODRPACK UG p. 38).
stopreason [list of str, optional] *info* interpreted into English.

Methods

pprint()	Pretty-print important results.

scipy.odr.Output.pprint

Output.**pprint**()

Pretty-print important results.

scipy.odr.odr

scipy.odr.**odr**(*fcn*, *beta0*, *y*, *x*, *we=None*, *wd=None*, *fjacb=None*, *fjacd=None*, *extra_args=None*, *ifixx=None*, *ifixb=None*, *job=0*, *iprint=0*, *errfile=None*, *rptfile=None*, *ndigit=0*, *taufac=0.0*, *sstol=- 1.0*, *partol=- 1.0*, *maxit=- 1*, *stpb=None*, *stpd=None*, *sclb=None*, *scld=None*, *work=None*, *iwork=None*, *full_output=0*)

Low-level function for ODR.

See also:

ODR

The ODR class gathers all information and coordinates the running of the main fitting routine.

Model

The Model class stores information about the function you wish to fit.

Data

The data to fit.

RealData

Data with weights as actual std. dev.s and/or covariances.

Notes

This is a function performing the same operation as the *ODR*, *Model*, and *Data* classes together. The parameters of this function are explained in the class documentation.

scipy.odr.OdrWarning

exception scipy.odr.**OdrWarning**

Warning indicating that the data passed into ODR will cause problems when passed into 'odr' that the user should be aware of.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

scipy.odr.OdrError

exception scipy.odr.**OdrError**

Exception indicating an error in fitting.

This is raised by *odr* if an error occurs during fitting.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

scipy.odr.OdrStop

exception scipy.odr.**OdrStop**

Exception stopping fitting.

You can raise this exception in your objective function to tell *odr* to stop fitting.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

scipy.odr.polynomial

scipy.odr.**polynomial**(*order*)

Factory function for a general polynomial model.

Parameters

order [int or sequence] If an integer, it becomes the order of the polynomial to fit. If a sequence of numbers, then these are the explicit powers in the polynomial. A constant term (power 0) is always included, so don't include 0. Thus, polynomial(n) is equivalent to polynomial(range(1, n+1)).

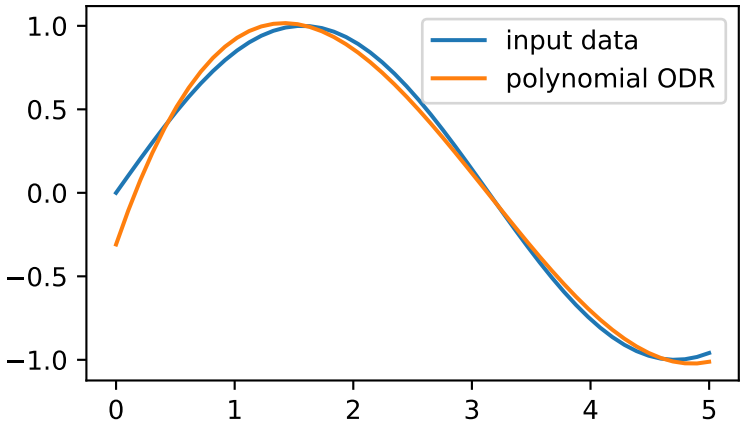
Returns

polynomial
[Model instance] Model instance.

Examples

We can fit an input data using orthogonal distance regression (ODR) with a polynomial model:

```
>>> import matplotlib.pyplot as plt
>>> from scipy import odr
>>> x = np.linspace(0.0, 5.0)
>>> y = np.sin(x)
>>> poly_model = odr.polynomial(3)  # using third order polynomial model
>>> data = odr.Data(x, y)
>>> odr_obj = odr.ODR(data, poly_model)
>>> output = odr_obj.run()  # running ODR fitting
>>> poly = np.poly1d(output.beta[::-1])
>>> poly_y = poly(x)
>>> plt.plot(x, y, label="input data")
>>> plt.plot(x, poly_y, label="polynomial ODR")
>>> plt.legend()
>>> plt.show()
```



scipy.odr.exponential

scipy.odr.**exponential = <scipy.odr.models._ExponentialModel object>**

Exponential model

This model is defined by $y = \beta_0 + e^{\beta_1 x}$

Examples

We can calculate orthogonal distance regression with an exponential model:

```
>>> from scipy import odr
>>> x = np.linspace(0.0, 5.0)
>>> y = -10.0 + np.exp(0.5*x)
>>> data = odr.Data(x, y)
>>> odr_obj = odr.ODR(data, odr.exponential)
>>> output = odr_obj.run()
>>> print(output.beta)
[-10.    0.5]
```

scipy.odr.multilinear

scipy.odr.**multilinear = <scipy.odr.models._MultilinearModel object>**

Arbitrary-dimensional linear model

This model is defined by $y = \beta_0 + \sum_{i=1}^{m} \beta_i x_i$

Examples

We can calculate orthogonal distance regression with an arbitrary dimensional linear model:

```
>>> from scipy import odr
>>> x = np.linspace(0.0, 5.0)
>>> y = 10.0 + 5.0 * x
>>> data = odr.Data(x, y)
>>> odr_obj = odr.ODR(data, odr.multilinear)
>>> output = odr_obj.run()
>>> print(output.beta)
[10.  5.]
```

scipy.odr.unilinear

scipy.odr.**unilinear = <scipy.odr.models._UnilinearModel object>**

Univariate linear model

This model is defined by $y = \beta_0 x + \beta_1$

Examples

We can calculate orthogonal distance regression with an unilinear model:

```
>>> from scipy import odr
>>> x = np.linspace(0.0, 5.0)
>>> y = 1.0 * x + 2.0
>>> data = odr.Data(x, y)
>>> odr_obj = odr.ODR(data, odr.unilinear)
>>> output = odr_obj.run()
>>> print(output.beta)
[1. 2.]
```

scipy.odr.quadratic

scipy.odr.**quadratic = <scipy.odr.models._QuadraticModel object>**

Quadratic model

This model is defined by $y = \beta_0 x^2 + \beta_1 x + \beta_2$

Examples

We can calculate orthogonal distance regression with a quadratic model:

```
>>> from scipy import odr
>>> x = np.linspace(0.0, 5.0)
>>> y = 1.0 * x ** 2 + 2.0 * x + 3.0
>>> data = odr.Data(x, y)
>>> odr_obj = odr.ODR(data, odr.quadratic)
>>> output = odr_obj.run()
>>> print(output.beta)
[1. 2. 3.]
```

Usage information

Introduction

Why Orthogonal Distance Regression (ODR)? Sometimes one has measurement errors in the explanatory (a.k.a., "independent") variable(s), not just the response (a.k.a., "dependent") variable(s). Ordinary Least Squares (OLS) fitting procedures treat the data for explanatory variables as fixed, i.e., not subject to error of any kind. Furthermore, OLS procedures require that the response variables be an explicit function of the explanatory variables; sometimes making the equation explicit is impractical and/or introduces errors. ODR can handle both of these cases with ease, and can even reduce to the OLS case if that is sufficient for the problem.

ODRPACK is a FORTRAN-77 library for performing ODR with possibly non-linear fitting functions. It uses a modified trust-region Levenberg-Marquardt-type algorithm [1] to estimate the function parameters. The fitting functions are provided by Python functions operating on NumPy arrays. The required derivatives may be provided by Python functions as well, or may be estimated numerically. ODRPACK can do explicit or implicit ODR fits, or it can do OLS. Input and output variables may be multidimensional. Weights can be provided to account for different variances of the observations, and even covariances between dimensions of the variables.

The *scipy.odr* package offers an object-oriented interface to ODRPACK, in addition to the low-level *odr* function.

Additional background information about ODRPACK can be found in the ODRPACK User's Guide, reading which is recommended.

Basic usage

1. Define the function you want to fit against.:

```
def f(B, x):
    '''Linear function y = m*x + b'''
    # B is a vector of the parameters.
    # x is an array of the current x values.
    # x is in the same format as the x passed to Data or RealData.
    #
    # Return an array in the same format as y passed to Data or RealData.
    return B[0]*x + B[1]
```

2. Create a Model.:

```
linear = Model(f)
```

3. Create a Data or RealData instance.:

```
mydata = Data(x, y, wd=1./power(sx,2), we=1./power(sy,2))
```

   or, when the actual covariances are known:

```
mydata = RealData(x, y, sx=sx, sy=sy)
```

4. Instantiate ODR with your data, model and initial parameter estimate.:

```
myodr = ODR(mydata, linear, beta0=[1., 2.])
```

5. Run the fit.:

```
myoutput = myodr.run()
```

6. Examine output.:

```
myoutput.pprint()
```

3.3.19 Optimization and root finding (`scipy.optimize`)

SciPy `optimize` provides functions for minimizing (or maximizing) objective functions, possibly subject to constraints. It includes solvers for nonlinear problems (with support for both local and global optimization algorithms), linear programing, constrained and nonlinear least-squares, root finding, and curve fitting.

Common functions and objects, shared across different solvers, are:

show_options([solver, method, disp])	Show documentation for additional options of optimization solvers.
OptimizeResult	Represents the optimization result.
OptimizeWarning	

scipy.optimize.show_options

scipy.optimize.**show_options**(*solver=None*, *method=None*, *disp=True*)

Show documentation for additional options of optimization solvers.

These are method-specific options that can be supplied through the `options` dict.

Parameters

solver	[str] Type of optimization solver. One of 'minimize', 'minimize_scalar', 'root', 'root_scalar', 'linprog', or 'quadratic_assignment'.
method	[str, optional] If not given, shows all methods of the specified solver. Otherwise, show only the options for the specified method. Valid values corresponds to methods' names of respective solver (e.g., 'BFGS' for 'minimize').
disp	[bool, optional] Whether to print the result rather than returning it.

Returns

text	Either None (for disp=True) or the text string (disp=False)

Notes

The solver-specific methods are:

`scipy.optimize.minimize`

- *Nelder-Mead*
- *Powell*
- *CG*
- *BFGS*
- *Newton-CG*
- *L-BFGS-B*
- *TNC*
- *COBYLA*
- *SLSQP*
- *dogleg*
- *trust-ncg*

`scipy.optimize.root`

- *hybr*
- *lm*
- *broyden1*
- *broyden2*
- *anderson*
- *linearmixing*
- *diagbroyden*
- *excitingmixing*
- *krylov*

- *df-sane*

scipy.optimize.minimize_scalar

- *brent*
- *golden*
- *bounded*

scipy.optimize.root_scalar

- *bisect*
- *brentq*
- *brenth*
- *ridder*
- *toms748*
- *newton*
- *secant*
- *halley*

scipy.optimize.linprog

- *simplex*
- *interior-point*
- *revised simplex*
- *highs*
- *highs-ds*
- *highs-ipm*

scipy.optimize.quadratic_assignment

- *faq*
- *2opt*

Examples

We can print documentations of a solver in stdout:

```
>>> from scipy.optimize import show_options
>>> show_options(solver="minimize")
...
```

Specifying a method is possible:

```
>>> show_options(solver="minimize", method="Nelder-Mead")
...
```

We can also get the documentations as a string:

```
>>> show_options(solver="minimize", method="Nelder-Mead", disp=False)
Minimization of scalar function of one or more variables using the ...
```

scipy.optimize.OptimizeResult

class scipy.optimize.**OptimizeResult**
Represents the optimization result.

Notes

There may be additional attributes not listed above depending of the specific solver. Since this class is essentially a subclass of dict with attribute accessors, one can see which attributes are available using the *keys()* method.

Attributes

x [ndarray] The solution of the optimization.
success [bool] Whether or not the optimizer exited successfully.
status [int] Termination status of the optimizer. Its value depends on the underlying solver. Refer to *message* for details.
message [str] Description of the cause of the termination.
fun, jac, hess: ndarray
Values of objective function, its Jacobian and its Hessian (if available). The Hessians may be approximations, see the documentation of the function in question.
hess_inv [object] Inverse of the objective function's Hessian; may be an approximation. Not available for all solvers. The type of this attribute may be either np.ndarray or scipy.sparse.linalg.LinearOperator.
nfev, njev, nhev
[int] Number of evaluations of the objective functions and of its Jacobian and Hessian.
nit [int] Number of iterations performed by the optimizer.
maxcv [float] The maximum constraint violation.

Methods

__getitem__	x.__getitem__(y) <==> x[y]
__len__(/)	Return len(self).
clear()	
copy()	
fromkeys(iterable[, value])	Create a new dictionary with keys from iterable and values set to value.
get(key[, default])	Return the value for key if key is in the dictionary, else default.
items()	
keys()	
pop(k[,d])	If key is not found, d is returned if given, otherwise KeyError is raised
popitem(/)	Remove and return a (key, value) pair as a 2-tuple.
setdefault(key[, default])	Insert key with a value of default if key is not in the dictionary.

continues on next page

Table 121 – continued from previous page

update([E,]**F)	If E is present and has a .keys() method, then does: for k in E: D[k] = E[k] If E is present and lacks a .keys() method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]
values()	

scipy.optimize.OptimizeResult.__getitem__

OptimizeResult.**__getitem__**()
x.__getitem__(y) <==> x[y]

scipy.optimize.OptimizeResult.__len__

OptimizeResult.**__len__**(/)
Return len(self).

scipy.optimize.OptimizeResult.clear

OptimizeResult.**clear**() → None. Remove all items from D.

scipy.optimize.OptimizeResult.copy

OptimizeResult.**copy**() → a shallow copy of D

scipy.optimize.OptimizeResult.fromkeys

OptimizeResult.**fromkeys**(*iterable*, *value=None*, /)
Create a new dictionary with keys from iterable and values set to value.

scipy.optimize.OptimizeResult.get

OptimizeResult.**get**(*key*, *default=None*, /)
Return the value for key if key is in the dictionary, else default.

scipy.optimize.OptimizeResult.items

OptimizeResult.**items**() → a set-like object providing a view on D's items

scipy.optimize.OptimizeResult.keys

OptimizeResult.**keys**() → a set-like object providing a view on D's keys

scipy.optimize.OptimizeResult.pop

OptimizeResult.**pop**(*k*[, *d*]) → v, remove specified key and return the corresponding value.
If key is not found, d is returned if given, otherwise KeyError is raised

scipy.optimize.OptimizeResult.popitem

OptimizeResult.**popitem**(/)
Remove and return a (key, value) pair as a 2-tuple.

Pairs are returned in LIFO (last-in, first-out) order. Raises KeyError if the dict is empty.

scipy.optimize.OptimizeResult.setdefault

OptimizeResult.**setdefault**(*key*, *default=None*, */*)
Insert key with a value of default if key is not in the dictionary.

Return the value for key if key is in the dictionary, else default.

scipy.optimize.OptimizeResult.update

OptimizeResult.**update**([*E*], ***F*) → None. Update D from dict/iterable E and F.
If E is present and has a .keys() method, then does: for k in E: D[k] = E[k] If E is present and lacks a .keys() method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]

scipy.optimize.OptimizeResult.values

OptimizeResult.**values**() → an object providing a view on D's values

scipy.optimize.OptimizeWarning

exception scipy.optimize.**OptimizeWarning**

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

Optimization

Scalar functions optimization

minimize_scalar(fun[, bracket, bounds, …])	Minimization of scalar function of one variable.

scipy.optimize.minimize_scalar

scipy.optimize.**minimize_scalar**(*fun*, *bracket=None*, *bounds=None*, *args=()*, *method='brent'*, *tol=None*, *options=None*)
Minimization of scalar function of one variable.

Parameters

fun [callable] Objective function. Scalar function, must return a scalar.

bracket [sequence, optional] For methods 'brent' and 'golden', *bracket* defines the bracketing interval and can either have three items `(a, b, c)` so that `a < b < c` and `fun(b) < fun(a), fun(c)` or two items `a` and `c` which are assumed to be a starting interval for a downhill bracket search (see *bracket*); it doesn't always mean that the obtained solution will satisfy `a <= x <= c`.

bounds [sequence, optional] For method 'bounded', *bounds* is mandatory and must have two items corresponding to the optimization bounds.

args [tuple, optional] Extra arguments passed to the objective function.

method [str or callable, optional] Type of solver. Should be one of:

- 'Brent' *(see here)*
- 'Bounded' *(see here)*
- 'Golden' *(see here)*
- custom - a callable object (added in version 0.14.0), see below

tol [float, optional] Tolerance for termination. For detailed control, use solver-specific options.

options [dict, optional] A dictionary of solver options.
maxiter [int] Maximum number of iterations to perform.
disp [bool] Set to True to print convergence messages.
See *show_options* for solver-specific options.

Returns

res [OptimizeResult] The optimization result represented as a `OptimizeResult` object. Important attributes are: `x` the solution array, `success` a Boolean flag indicating if the optimizer exited successfully and `message` which describes the cause of the termination. See *OptimizeResult* for a description of other attributes.

See also:

minimize

Interface to minimization algorithms for scalar multivariate functions

show_options

Additional options accepted by the solvers

Notes

This section describes the available solvers that can be selected by the 'method' parameter. The default method is *Brent*.

Method *Brent* uses Brent's algorithm to find a local minimum. The algorithm uses inverse parabolic interpolation when possible to speed up convergence of the golden section method.

Method *Golden* uses the golden section search technique. It uses analog of the bisection method to decrease the bracketed interval. It is usually preferable to use the *Brent* method.

Method *Bounded* can perform bounded minimization. It uses the Brent method to find a local minimum in the interval x1 < xopt < x2.

Custom minimizers

It may be useful to pass a custom minimization method, for example when using some library frontend to minimize_scalar. You can simply pass a callable as the `method` parameter.

The callable is called as `method(fun, args, **kwargs, **options)` where `kwargs` corresponds to any other parameters passed to *minimize* (such as *bracket*, *tol*, etc.), except the *options* dict, which has its contents also passed as *method* parameters pair by pair. The method shall return an *OptimizeResult* object.

The provided *method* callable must be able to accept (and possibly ignore) arbitrary parameters; the set of parameters accepted by *minimize* may expand in future versions and then these parameters will be passed to the method. You can find an example in the scipy.optimize tutorial.

New in version 0.11.0.

Examples

Consider the problem of minimizing the following function.

```
>>> def f(x):
...     return (x - 2) * x * (x + 2)**2
```

Using the *Brent* method, we find the local minimum as:

```
>>> from scipy.optimize import minimize_scalar
>>> res = minimize_scalar(f)
>>> res.x
1.28077640403
```

Using the *Bounded* method, we find a local minimum with specified bounds as:

```
>>> res = minimize_scalar(f, bounds=(-3, -1), method='bounded')
>>> res.x
-2.0000002026
```

The *minimize_scalar* function supports the following methods:

minimize_scalar(method='brent')

scipy.optimize.**minimize_scalar**(*fun*, *args=()*, *method='brent'*, *tol=None*, *options={'func': None, 'brack': None, 'xtol': 1.48e-08, 'maxiter': 500}*)

See also:

For documentation for the rest of the parameters, see *scipy.optimize.minimize_scalar*

Options

maxiter [int] Maximum number of iterations to perform.
xtol [float] Relative error in solution *xopt* acceptable for convergence.

Notes

Uses inverse parabolic interpolation when possible to speed up convergence of golden section method.

minimize_scalar(method='bounded')

scipy.optimize.**minimize_scalar**(*fun*, *bounds=None*, *args=()*, *method='bounded'*, *tol=None*, *options={'func': None, 'xatol': 1e-05, 'maxiter': 500, 'disp': 0}*)

See also:

For documentation for the rest of the parameters, see *scipy.optimize.minimize_scalar*

Options

maxiter [int] Maximum number of iterations to perform.
disp: int, optional

If non-zero, print messages.
0 : no message printing. 1 : non-convergence notification messages only. 2 : print a message on convergence too. 3 : print iteration results.

xatol [float] Absolute error in solution *xopt* acceptable for convergence.

minimize_scalar(method='golden')

scipy.optimize.**minimize_scalar**(*fun*, *args=()*, *method='golden'*, *tol=None*, *options={'func': None, 'brack': None, 'xtol': 1.4901161193847656e-08, 'maxiter': 5000}*)

See also:

For documentation for the rest of the parameters, see *scipy.optimize.minimize_scalar*

Options

maxiter [int] Maximum number of iterations to perform.
xtol [float] Relative error in solution *xopt* acceptable for convergence.

Local (multivariate) optimization

minimize(fun, x0[, args, method, jac, hess, …])	Minimization of scalar function of one or more variables.

scipy.optimize.minimize

scipy.optimize.**minimize**(*fun*, *x0*, *args=()*, *method=None*, *jac=None*, *hess=None*, *hessp=None*, *bounds=None*, *constraints=()*, *tol=None*, *callback=None*, *options=None*)

Minimization of scalar function of one or more variables.

Parameters

fun [callable] The objective function to be minimized.

```
fun(x, *args) -> float
```

where `x` is an 1-D array with shape (n,) and `args` is a tuple of the fixed parameters needed to completely specify the function.

x0 [ndarray, shape (n,)] Initial guess. Array of real elements of size (n,), where 'n' is the number of independent variables.

args [tuple, optional] Extra arguments passed to the objective function and its derivatives (*fun*, *jac* and *hess* functions).

method [str or callable, optional] Type of solver. Should be one of

- 'Nelder-Mead' *(see here)*
- 'Powell' *(see here)*
- 'CG' *(see here)*
- 'BFGS' *(see here)*
- 'Newton-CG' *(see here)*
- 'L-BFGS-B' *(see here)*
- 'TNC' *(see here)*
- 'COBYLA' *(see here)*
- 'SLSQP' *(see here)*
- 'trust-constr'*(see here)*
- 'dogleg' *(see here)*
- 'trust-ncg' *(see here)*
- 'trust-exact' *(see here)*

- 'trust-krylov' *(see here)*
- custom - a callable object (added in version 0.14.0), see below for description.

If not given, chosen to be one of `BFGS`, `L-BFGS-B`, `SLSQP`, depending if the problem has constraints or bounds.

jac [{callable, '2-point', '3-point', 'cs', bool}, optional] Method for computing the gradient vector. Only for CG, BFGS, Newton-CG, L-BFGS-B, TNC, SLSQP, dogleg, trust-ncg, trust-krylov, trust-exact and trust-constr. If it is a callable, it should be a function that returns the gradient vector:

```
jac(x, *args) -> array_like, shape (n,)
```

where `x` is an array with shape (n,) and `args` is a tuple with the fixed parameters. If *jac* is a Boolean and is True, *fun* is assumed to return a tuple `(f, g)` containing the objective function and the gradient. Methods 'Newton-CG', 'trust-ncg', 'dogleg', 'trust-exact', and 'trust-krylov' require that either a callable be supplied, or that *fun* return the objective and gradient. If None or False, the gradient will be estimated using 2-point finite difference estimation with an absolute step size. Alternatively, the keywords {'2-point', '3-point', 'cs'} can be used to select a finite difference scheme for numerical estimation of the gradient with a relative step size. These finite difference schemes obey any specified *bounds*.

hess [{callable, '2-point', '3-point', 'cs', HessianUpdateStrategy}, optional] Method for computing the Hessian matrix. Only for Newton-CG, dogleg, trust-ncg, trust-krylov, trust-exact and trust-constr. If it is callable, it should return the Hessian matrix:

```
hess(x, *args) -> {LinearOperator, spmatrix, array}, (n, n)
```

where x is a (n,) ndarray and *args* is a tuple with the fixed parameters. LinearOperator and sparse matrix returns are only allowed for 'trust-constr' method. Alternatively, the keywords {'2-point', '3-point', 'cs'} select a finite difference scheme for numerical estimation. Or, objects implementing the *HessianUpdateStrategy* interface can be used to approximate the Hessian. Available quasi-Newton methods implementing this interface are:

- *BFGS*;
- *SR1*.

Whenever the gradient is estimated via finite-differences, the Hessian cannot be estimated with options {'2-point', '3-point', 'cs'} and needs to be estimated using one of the quasi-Newton strategies. 'trust-exact' cannot use a finite-difference scheme, and must be used with a callable returning an (n, n) array.

hessp [callable, optional] Hessian of objective function times an arbitrary vector p. Only for Newton-CG, trust-ncg, trust-krylov, trust-constr. Only one of *hessp* or *hess* needs to be given. If *hess* is provided, then *hessp* will be ignored. *hessp* must compute the Hessian times an arbitrary vector:

```
hessp(x, p, *args) -> ndarray shape (n,)
```

where x is a (n,) ndarray, p is an arbitrary vector with dimension (n,) and *args* is a tuple with the fixed parameters.

bounds [sequence or *Bounds*, optional] Bounds on variables for Nelder-Mead, L-BFGS-B, TNC, SLSQP, Powell, and trust-constr methods. There are two ways to specify the bounds:

1. Instance of *Bounds* class.
2. Sequence of `(min, max)` pairs for each element in *x*. None is used to specify no bound.

constraints

[{Constraint, dict} or List of {Constraint, dict}, optional] Constraints definition (only for COBYLA, SLSQP and trust-constr).

Constraints for 'trust-constr' are defined as a single object or a list of objects specifying constraints to the optimization problem. Available constraints are:

- *LinearConstraint*
- *NonlinearConstraint*

Constraints for COBYLA, SLSQP are defined as a list of dictionaries. Each dictionary with fields:

type [str] Constraint type: 'eq' for equality, 'ineq' for inequality.

fun [callable] The function defining the constraint.

jac [callable, optional] The Jacobian of *fun* (only for SLSQP).
args [sequence, optional] Extra arguments to be passed to the function and Jacobian.

Equality constraint means that the constraint function result is to be zero whereas inequality means that it is to be non-negative. Note that COBYLA only supports inequality constraints.

tol [float, optional] Tolerance for termination. When *tol* is specified, the selected minimization algorithm sets some relevant solver-specific tolerance(s) equal to *tol*. For detailed control, use solver-specific options.

options [dict, optional] A dictionary of solver options. All methods accept the following generic options:

maxiter [int] Maximum number of iterations to perform. Depending on the method each iteration may use several function evaluations.
disp [bool] Set to True to print convergence messages.

For method-specific options, see `show_options`.

callback [callable, optional] Called after each iteration. For 'trust-constr' it is a callable with the signature:

```
callback(xk, OptimizeResult state) -> bool
```

where `xk` is the current parameter vector. and `state` is an `OptimizeResult` object, with the same fields as the ones from the return. If callback returns True the algorithm execution is terminated. For all the other methods, the signature is:

```
callback(xk)
```

where `xk` is the current parameter vector.

Returns

res [OptimizeResult] The optimization result represented as a `OptimizeResult` object. Important attributes are: `x` the solution array, `success` a Boolean flag indicating if the optimizer exited successfully and `message` which describes the cause of the termination. See `OptimizeResult` for a description of other attributes.

Interface to minimization algorithms for scalar univariate functions

show_options

Additional options accepted by the solvers

Notes

This section describes the available solvers that can be selected by the 'method' parameter. The default method is *BFGS*.

Unconstrained minimization

Method *CG* uses a nonlinear conjugate gradient algorithm by Polak and Ribiere, a variant of the Fletcher-Reeves method described in [5] pp.120-122. Only the first derivatives are used.

Method *BFGS* uses the quasi-Newton method of Broyden, Fletcher, Goldfarb, and Shanno (BFGS) [5] pp. 136. It uses the first derivatives only. BFGS has proven good performance even for non-smooth optimizations. This method also returns an approximation of the Hessian inverse, stored as *hess_inv* in the OptimizeResult object.

Method *Newton-CG* uses a Newton-CG algorithm [5] pp. 168 (also known as the truncated Newton method). It uses a CG method to the compute the search direction. See also *TNC* method for a box-constrained minimization with a similar algorithm. Suitable for large-scale problems.

Method *dogleg* uses the dog-leg trust-region algorithm [5] for unconstrained minimization. This algorithm requires the gradient and Hessian; furthermore the Hessian is required to be positive definite.

Method *trust-ncg* uses the Newton conjugate gradient trust-region algorithm [5] for unconstrained minimization. This algorithm requires the gradient and either the Hessian or a function that computes the product of the Hessian with a given vector. Suitable for large-scale problems.

Method *trust-krylov* uses the Newton GLTR trust-region algorithm [14], [15] for unconstrained minimization. This algorithm requires the gradient and either the Hessian or a function that computes the product of the Hessian with a given vector. Suitable for large-scale problems. On indefinite problems it requires usually less iterations than the *trust-ncg* method and is recommended for medium and large-scale problems.

Method *trust-exact* is a trust-region method for unconstrained minimization in which quadratic subproblems are solved almost exactly [13]. This algorithm requires the gradient and the Hessian (which is *not* required to be positive definite). It is, in many situations, the Newton method to converge in fewer iteraction and the most recommended for small and medium-size problems.

Bound-Constrained minimization

Method *Nelder-Mead* uses the Simplex algorithm [1], [2]. This algorithm is robust in many applications. However, if numerical computation of derivative can be trusted, other algorithms using the first and/or second derivatives information might be preferred for their better performance in general.

Method *L-BFGS-B* uses the L-BFGS-B algorithm [6], [7] for bound constrained minimization.

Method *Powell* is a modification of Powell's method [3], [4] which is a conjugate direction method. It performs sequential one-dimensional minimizations along each vector of the directions set (*direc* field in *options* and *info*), which is updated at each iteration of the main minimization loop. The function need not be differentiable, and no derivatives are taken. If bounds are not provided, then an unbounded line search will be used. If bounds are provided and the initial guess is within the bounds, then every function evaluation throughout the minimization procedure will be within the bounds. If bounds are provided, the initial guess is outside the bounds, and *direc* is full rank (default has full rank), then some function evaluations during the first iteration may be outside the bounds, but every function evaluation after the first iteration will be within the bounds. If *direc* is not full rank, then some parameters may not be optimized and the solution is not guaranteed to be within the bounds.

Method *TNC* uses a truncated Newton algorithm [5], [8] to minimize a function with variables subject to bounds. This algorithm uses gradient information; it is also called Newton Conjugate-Gradient. It differs from the *Newton-CG* method described above as it wraps a C implementation and allows each variable to be given upper and lower bounds.

Constrained Minimization

Method *COBYLA* uses the Constrained Optimization BY Linear Approximation (COBYLA) method [9], [10], [11]. The algorithm is based on linear approximations to the objective function and each constraint. The method wraps a FORTRAN implementation of the algorithm. The constraints functions 'fun' may return either a single number or an array or list of numbers.

Method *SLSQP* uses Sequential Least SQuares Programming to minimize a function of several variables with any combination of bounds, equality and inequality constraints. The method wraps the SLSQP Optimization subroutine originally implemented by Dieter Kraft [12]. Note that the wrapper handles infinite values in bounds by converting them into large floating values.

Method *trust-constr* is a trust-region algorithm for constrained optimization. It swiches between two implementations depending on the problem definition. It is the most versatile constrained minimization algorithm implemented in SciPy and the most appropriate for large-scale problems. For equality constrained problems it is an implementation of Byrd-Omojokun Trust-Region SQP method described in [17] and in [5], p. 549. When inequality constraints are imposed as well, it swiches to the trust-region interior point method described in [16]. This interior point algorithm, in turn, solves inequality constraints by introducing slack variables and solving a sequence of equality-constrained barrier problems for progressively smaller values of the barrier parameter. The previously

described equality constrained SQP method is used to solve the subproblems with increasing levels of accuracy as the iterate gets closer to a solution.

Finite-Difference Options

For Method *trust-constr* the gradient and the Hessian may be approximated using three finite-difference schemes: {'2-point', '3-point', 'cs'}. The scheme 'cs' is, potentially, the most accurate but it requires the function to correctly handles complex inputs and to be differentiable in the complex plane. The scheme '3-point' is more accurate than '2-point' but requires twice as many operations.

Custom minimizers

It may be useful to pass a custom minimization method, for example when using a frontend to this method such as *scipy.optimize.basinhopping* or a different library. You can simply pass a callable as the `method` parameter.

The callable is called as `method(fun, x0, args, **kwargs, **options)` where `kwargs` corresponds to any other parameters passed to *minimize* (such as *callback*, *hess*, etc.), except the *options* dict, which has its contents also passed as *method* parameters pair by pair. Also, if *jac* has been passed as a bool type, *jac* and *fun* are mangled so that *fun* returns just the function values and *jac* is converted to a function returning the Jacobian. The method shall return an *OptimizeResult* object.

The provided *method* callable must be able to accept (and possibly ignore) arbitrary parameters; the set of parameters accepted by *minimize* may expand in future versions and then these parameters will be passed to the method. You can find an example in the scipy.optimize tutorial.

New in version 0.11.0.

Examples

Let us consider the problem of minimizing the Rosenbrock function. This function (and its respective derivatives) is implemented in *rosen* (resp. *rosen_der*, *rosen_hess*) in the *scipy.optimize*.

```
>>> from scipy.optimize import minimize, rosen, rosen_der
```

A simple application of the *Nelder-Mead* method is:

```
>>> x0 = [1.3, 0.7, 0.8, 1.9, 1.2]
>>> res = minimize(rosen, x0, method='Nelder-Mead', tol=1e-6)
>>> res.x
array([ 1.,  1.,  1.,  1.,  1.])
```

Now using the *BFGS* algorithm, using the first derivative and a few options:

```
>>> res = minimize(rosen, x0, method='BFGS', jac=rosen_der,
...                options={'gtol': 1e-6, 'disp': True})
Optimization terminated successfully.
         Current function value: 0.000000
         Iterations: 26
         Function evaluations: 31
         Gradient evaluations: 31
>>> res.x
```

(continues on next page)

(continued from previous page)

```
array([ 1.,  1.,  1.,  1.,  1.])
>>> print(res.message)
Optimization terminated successfully.
>>> res.hess_inv
array([[ 0.00749589,  0.01255155,  0.02396251,  0.04750988,  0.09495377],␣
 ↪ # may vary
       [ 0.01255155,  0.02510441,  0.04794055,  0.09502834,  0.18996269],
       [ 0.02396251,  0.04794055,  0.09631614,  0.19092151,  0.38165151],
       [ 0.04750988,  0.09502834,  0.19092151,  0.38341252,  0.7664427 ],
       [ 0.09495377,  0.18996269,  0.38165151,  0.7664427,   1.53713523]])
```

Next, consider a minimization problem with several constraints (namely Example 16.4 from [5]). The objective function is:

```
>>> fun = lambda x: (x[0] - 1)**2 + (x[1] - 2.5)**2
```

There are three constraints defined as:

```
>>> cons = ({'type': 'ineq', 'fun': lambda x:  x[0] - 2 * x[1] + 2},
...         {'type': 'ineq', 'fun': lambda x: -x[0] - 2 * x[1] + 6},
...         {'type': 'ineq', 'fun': lambda x: -x[0] + 2 * x[1] + 2})
```

And variables must be positive, hence the following bounds:

```
>>> bnds = ((0, None), (0, None))
```

The optimization problem is solved using the SLSQP method as:

```
>>> res = minimize(fun, (2, 0), method='SLSQP', bounds=bnds,
...                constraints=cons)
```

It should converge to the theoretical solution (1.4 ,1.7).

The *minimize* function supports the following methods:

minimize(method='Nelder-Mead')

scipy.optimize.**minimize**(*fun*, *x0*, *args=()*, *method='Nelder-Mead'*, *bounds=None*, *tol=None*, *callback=None*, *options={'func': None, 'maxiter': None, 'maxfev': None, 'disp': False, 'return_all': False, 'initial_simplex': None, 'xatol': 0.0001, 'fatol': 0.0001, 'adaptive': False}*)

Minimization of scalar function of one or more variables using the Nelder-Mead algorithm.

See also:

For documentation for the rest of the parameters, see *scipy.optimize.minimize*

Options

disp [bool] Set to True to print convergence messages.

maxiter, maxfev
[int] Maximum allowed number of iterations and function evaluations. Will default to `N*200`, where `N` is the number of variables, if neither *maxiter* or *maxfev* is set. If both *maxiter* and *maxfev* are set, minimization will stop at the first reached.

return_all [bool, optional] Set to True to return a list of the best solution at each of the iterations.

initial_simplex
: [array_like of shape (N + 1, N)] Initial simplex. If given, overrides *x0*. `initial_simplex[j,:]` should contain the coordinates of the jth vertex of the `N+1` vertices in the simplex, where `N` is the dimension.

xatol
: [float, optional] Absolute error in xopt between iterations that is acceptable for convergence.

fatol
: [number, optional] Absolute error in func(xopt) between iterations that is acceptable for convergence.

adaptive
: [bool, optional] Adapt algorithm parameters to dimensionality of problem. Useful for high-dimensional minimization [1].

bounds
: [sequence or *Bounds*, optional] Bounds on variables. There are two ways to specify the bounds:
  1. Instance of *Bounds* class.
  2. Sequence of `(min, max)` pairs for each element in *x*. None is used to specify no bound.

  Note that this just clips all vertices in simplex based on the bounds.

Options

disp [bool] Set to True to print convergence messages.
maxiter [int] Maximum number of iterations to perform.
gtol [float] Gradient norm must be less than *gtol* before successful termination.
norm [float] Order of norm (Inf is max, -Inf is min).
eps [float or ndarray] If *jac is None* the absolute step size used for numerical approximation of the jacobian via forward differences.
return_all [bool, optional] Set to True to return a list of the best solution at each of the iterations.
finite_diff_rel_step [None or array_like, optional] If *jac in ['2-point', '3-point', 'cs']* the relative step size to use for numerical approximation of the jacobian. The absolute step size is computed as `h = rel_step * sign(x0) * max(1, abs(x0))`, possibly adjusted to fit into the bounds. For `method='3-point'` the sign of *h* is ignored. If None (default) then step is selected automatically.

minimize(method='BFGS')

scipy.optimize.**minimize**(*fun*, *x0*, *args=()*, *method='BFGS'*, *jac=None*, *tol=None*, *callback=None*, *options={'gtol': 1e-05, 'norm': inf, 'eps': 1.4901161193847656e-08, 'maxiter': None, 'disp': False, 'return_all': False, 'finite_diff_rel_step': None}*)

Minimization of scalar function of one or more variables using the BFGS algorithm.

minimize(method='Newton-CG')

scipy.optimize.**minimize**(*fun*, *x0*, *args=()*, *method='Newton-CG'*, *jac=None*, *hess=None*, *hessp=None*, *tol=None*, *callback=None*, *options={'xtol': 1e-05, 'eps': 1.4901161193847656e-08, 'maxiter': None, 'disp': False, 'return_all': False}*)

Minimization of scalar function of one or more variables using the Newton-CG algorithm.

Note that the *jac* parameter (Jacobian) is required.

See also:

For documentation for the rest of the parameters, see *scipy.optimize.minimize*

Options

disp	[bool] Set to True to print convergence messages.
xtol	[float] Average relative error in solution *xopt* acceptable for convergence.
maxiter	[int] Maximum number of iterations to perform.
eps	[float or ndarray] If *hessp* is approximated, use this value for the step size.
return_all	[bool, optional] Set to True to return a list of the best solution at each of the iterations.

minimize(method='L-BFGS-B')

scipy.optimize.**minimize**(*fun*, *x0*, *args=()*, *method='L-BFGS-B'*, *jac=None*, *bounds=None*, *tol=None*, *callback=None*, *options={'disp': None, 'maxcor': 10, 'ftol': 2.220446049250313e-09, 'gtol': 1e-05, 'eps': 1e-08, 'maxfun': 15000, 'maxiter': 15000, 'iprint': - 1, 'maxls': 20, 'finite_diff_rel_step': None}*)

Minimize a scalar function of one or more variables using the L-BFGS-B algorithm.

See also:

For documentation for the rest of the parameters, see *scipy.optimize.minimize*

Options

disp	[None or int] If *disp is None* (the default), then the supplied version of *iprint* is used. If *disp is not None*, then it overrides the supplied version of *iprint* with the behaviour you outlined.
maxcor	[int] The maximum number of variable metric corrections used to define the limited memory matrix. (The limited memory BFGS method does not store the full hessian but uses this many terms in an approximation to it.)
ftol	[float] The iteration stops when `(f^k - f^{k+1})/max{|f^k|,|f^{k+1}|,1} <= ftol`.
gtol	[float] The iteration will stop when `max{|proj g_i | i = 1, ..., n} <= gtol` where `pg_i` is the i-th component of the projected gradient.
eps	[float or ndarray] If *jac is None* the absolute step size used for numerical approximation of the jacobian via forward differences.
maxfun	[int] Maximum number of function evaluations.
maxiter	[int] Maximum number of iterations.
iprint	[int, optional] Controls the frequency of output. `iprint < 0` means no output; `iprint = 0` print only one line at the last iteration; `0 < iprint < 99` print also f and `|proj g|` every iprint iterations; `iprint = 99` print details of every iteration except n-vectors; `iprint = 100` print also the changes of active set and final x; `iprint > 100` print details of every iteration including x and g.
callback	[callable, optional] Called after each iteration, as `callback(xk)`, where `xk` is the current parameter vector.

maxls [int, optional] Maximum number of line search steps (per iteration). Default is 20.

finite_diff_rel_step
[None or array_like, optional] If *jac in ['2-point', '3-point', 'cs']* the relative step size to use for numerical approximation of the jacobian. The absolute step size is computed as `h = rel_step * sign(x0) * max(1, abs(x0))`, possibly adjusted to fit into the bounds. For `method='3-point'` the sign of *h* is ignored. If None (default) then step is selected automatically.

Notes

The option *ftol* is exposed via the *scipy.optimize.minimize* interface, but calling *scipy.optimize.fmin_l_bfgs_b* directly exposes *factr*. The relationship between the two is `ftol = factr * numpy.finfo(float).eps`. I.e., *factr* multiplies the default machine floating-point precision to arrive at *ftol*.

minimize(method='TNC')

scipy.optimize.**minimize**(*fun*, *x0*, *args=()*, *method='TNC'*, *jac=None*, *bounds=None*, *tol=None*, *callback=None*, *options={'eps': 1e-08, 'scale': None, 'offset': None, 'mesg_num': None, 'maxCGit': - 1, 'maxiter': None, 'eta': - 1, 'stepmx': 0, 'accuracy': 0, 'minfev': 0, 'ftol': - 1, 'xtol': - 1, 'gtol': - 1, 'rescale': - 1, 'disp': False, 'finite_diff_rel_step': None, 'maxfun': None}*)

Minimize a scalar function of one or more variables using a truncated Newton (TNC) algorithm.

See also:

For documentation for the rest of the parameters, see *scipy.optimize.minimize*

Options

eps [float or ndarray] If *jac is None* the absolute step size used for numerical approximation of the jacobian via forward differences.

scale [list of floats] Scaling factors to apply to each variable. If None, the factors are up-low for interval bounded variables and 1+|x] fo the others. Defaults to None.

offset [float] Value to subtract from each variable. If None, the offsets are (up+low)/2 for interval bounded variables and x for the others.

disp [bool] Set to True to print convergence messages.

maxCGit [int] Maximum number of hessian*vector evaluations per main iteration. If maxCGit == 0, the direction chosen is -gradient if maxCGit < 0, maxCGit is set to max(1,min(50,n/2)). Defaults to -1.

maxiter [int, optional] Maximum number of function evaluations. This keyword is deprecated in favor of *maxfun*. Only if *maxfun* is None is this keyword used.

eta [float] Severity of the line search. If < 0 or > 1, set to 0.25. Defaults to -1.

stepmx [float] Maximum step for the line search. May be increased during call. If too small, it will be set to 10.0. Defaults to 0.

accuracy [float] Relative precision for finite difference calculations. If <= machine_precision, set to sqrt(machine_precision). Defaults to 0.

minfev [float] Minimum function value estimate. Defaults to 0.

ftol [float] Precision goal for the value of f in the stopping criterion. If ftol < 0.0, ftol is set to 0.0 defaults to -1.

xtol [float] Precision goal for the value of x in the stopping criterion (after applying x scaling factors). If xtol < 0.0, xtol is set to sqrt(machine_precision). Defaults to -1.

gtol [float] Precision goal for the value of the projected gradient in the stopping criterion (after applying x scaling factors). If gtol < 0.0, gtol is set to 1e-2 * sqrt(accuracy). Setting it to 0.0 is not recommended. Defaults to -1.

rescale [float] Scaling factor (in log10) used to trigger f value rescaling. If 0, rescale at each iteration. If a large value, never rescale. If < 0, rescale is set to 1.3.

finite_diff_rel_step
[None or array_like, optional] If *jac in ['2-point', '3-point', 'cs']* the relative step size to use for numerical approximation of the jacobian. The absolute step size is computed as `h = rel_step * sign(x0) * max(1, abs(x0))`, possibly adjusted to fit into the bounds. For `method='3-point'` the sign of *h* is ignored. If None (default) then step is selected automatically.

maxfun [int] Maximum number of function evaluations. If None, *maxfun* is set to max(100, 10*len(x0)). Defaults to None.

minimize(method='COBYLA')

scipy.optimize.**minimize**(*fun*, *x0*, *args=()*, *method='COBYLA'*, *constraints=()*, *tol=None*, *callback=None*, *options={'rhobeg': 1.0, 'maxiter': 1000, 'disp': False, 'catol': 0.0002}*)

Minimize a scalar function of one or more variables using the Constrained Optimization BY Linear Approximation (COBYLA) algorithm.

See also:

For documentation for the rest of the parameters, see *scipy.optimize.minimize*

Options

rhobeg [float] Reasonable initial changes to the variables.

tol [float] Final accuracy in the optimization (not precisely guaranteed). This is a lower bound on the size of the trust region.

disp [bool] Set to True to print convergence messages. If False, *verbosity* is ignored as set to 0.

maxiter [int] Maximum number of function evaluations.

catol [float] Tolerance (absolute) for constraint violations

minimize(method='SLSQP')

scipy.optimize.**minimize**(*fun*, *x0*, *args=()*, *method='SLSQP'*, *jac=None*, *bounds=None*, *constraints=()*, *tol=None*, *callback=None*, *options={'func': None, 'maxiter': 100, 'ftol': 1e-06, 'iprint': 1, 'disp': False, 'eps': 1.4901161193847656e-08, 'finite_diff_rel_step': None}*)

Minimize a scalar function of one or more variables using Sequential Least Squares Programming (SLSQP).

See also:

For documentation for the rest of the parameters, see *scipy.optimize.minimize*

Options

ftol [float] Precision goal for the value of f in the stopping criterion.

eps [float] Step size used for numerical approximation of the Jacobian.

disp [bool] Set to True to print convergence messages. If False, *verbosity* is ignored and set to 0.

maxiter [int] Maximum number of iterations.

finite_diff_rel_step
[None or array_like, optional] If *jac in ['2-point', '3-point', 'cs']* the relative step size to use for numerical approximation of *jac*. The absolute step size is computed as `h = rel_step * sign(x0) * max(1, abs(x0))`, possibly adjusted to fit into the bounds. For

`method='3-point'` the sign of *h* is ignored. If None (default) then step is selected automatically.

minimize(method='trust-constr')

scipy.optimize.**minimize**(*fun*, *x0*, *args=()*, *method='trust-constr'*, *hess=None*, *hessp=None*, *bounds=None*, *constraints=()*, *tol=None*, *callback=None*, *options={'grad': None, 'xtol': 1e-08, 'gtol': 1e-08, 'barrier_tol': 1e-08, 'sparse_jacobian': None, 'maxiter': 1000, 'verbose': 0, 'finite_diff_rel_step': None, 'initial_constr_penalty': 1.0, 'initial_tr_radius': 1.0, 'initial_barrier_parameter': 0.1, 'initial_barrier_tolerance': 0.1, 'factorization_method': None, 'disp': False}*)

Minimize a scalar function subject to constraints.

Parameters

gtol [float, optional] Tolerance for termination by the norm of the Lagrangian gradient. The algorithm will terminate when both the infinity norm (i.e., max abs value) of the Lagrangian gradient and the constraint violation are smaller than `gtol`. Default is 1e-8.

xtol [float, optional] Tolerance for termination by the change of the independent variable. The algorithm will terminate when `tr_radius < xtol`, where `tr_radius` is the radius of the trust region used in the algorithm. Default is 1e-8.

barrier_tol
[float, optional] Threshold on the barrier parameter for the algorithm termination. When inequality constraints are present, the algorithm will terminate only when the barrier parameter is less than *barrier_tol*. Default is 1e-8.

sparse_jacobian
[{bool, None}, optional] Determines how to represent Jacobians of the constraints. If bool, then Jacobians of all the constraints will be converted to the corresponding format. If None (default), then Jacobians won't be converted, but the algorithm can proceed only if they all have the same format.

initial_tr_radius: float, optional
Initial trust radius. The trust radius gives the maximum distance between solution points in consecutive iterations. It reflects the trust the algorithm puts in the local approximation of the optimization problem. For an accurate local approximation the trust-region should be large and for an approximation valid only close to the current point it should be a small one. The trust radius is automatically updated throughout the optimization process, with `initial_tr_radius` being its initial value. Default is 1 (recommended in [1], p. 19).

initial_constr_penalty
[float, optional] Initial constraints penalty parameter. The penalty parameter is used for balancing the requirements of decreasing the objective function and satisfying the constraints. It is used for defining the merit function: `merit_function(x) = fun(x) + constr_penalty * constr_norm_l2(x)`, where `constr_norm_l2(x)` is the l2 norm of a vector containing all the constraints. The merit function is used for accepting or rejecting trial points and `constr_penalty` weights the two conflicting goals of reducing objective function and constraints. The penalty is automatically updated throughout the optimization process, with `initial_constr_penalty` being its initial value. Default is 1 (recommended in [1], p 19).

initial_barrier_parameter, initial_barrier_tolerance: float, optional
Initial barrier parameter and initial tolerance for the barrier subproblem. Both are used only when inequality constraints are present. For dealing with optimization problems `min_x f(x)` subject to inequality constraints `c(x) <= 0` the algorithm introduces slack variables, solving the problem `min_(x,s) f(x) + barrier_parameter*sum(ln(s))`

subject to the equality constraints `c(x) + s = 0` instead of the original problem. This subproblem is solved for decreasing values of `barrier_parameter` and with decreasing tolerances for the termination, starting with `initial_barrier_parameter` for the barrier parameter and `initial_barrier_tolerance` for the barrier tolerance. Default is 0.1 for both values (recommended in [1] p. 19). Also note that `barrier_parameter` and `barrier_tolerance` are updated with the same prefactor.

factorization_method
: [string or None, optional] Method to factorize the Jacobian of the constraints. Use None (default) for the auto selection or one of:
- 'NormalEquation' (requires scikit-sparse)
- 'AugmentedSystem'
- 'QRFactorization'
- 'SVDFactorization'

The methods 'NormalEquation' and 'AugmentedSystem' can be used only with sparse constraints. The projections required by the algorithm will be computed using, respectively, the the normal equation and the augmented system approaches explained in [1]. 'NormalEquation' computes the Cholesky factorization of `A A.T` and 'AugmentedSystem' performs the LU factorization of an augmented system. They usually provide similar results. 'AugmentedSystem' is used by default for sparse matrices.
The methods 'QRFactorization' and 'SVDFactorization' can be used only with dense constraints. They compute the required projections using, respectively, QR and SVD factorizations. The 'SVDFactorization' method can cope with Jacobian matrices with deficient row rank and will be used whenever other factorization methods fail (which may imply the conversion of sparse matrices to a dense format when required). By default, 'QRFactorization' is used for dense matrices.

finite_diff_rel_step
: [None or array_like, optional] Relative step size for the finite difference approximation.

maxiter
: [int, optional] Maximum number of algorithm iterations. Default is 1000.

verbose
: [{0, 1, 2}, optional] Level of algorithm's verbosity:
- 0 (default) : work silently.
- 1 : display a termination report.
- 2 : display progress during iterations.
- 3 : display progress during iterations (more complete report).

disp
: [bool, optional] If True (default), then *verbose* will be set to 1 if it was 0.

Returns

`OptimizeResult` with the fields documented below. Note the following:

1. All values corresponding to the constraints are ordered as they were passed to the solver. And values corresponding to *bounds* constraints are put *after* other constraints.
2. All numbers of function, Jacobian or Hessian evaluations correspond to numbers of actual Python function calls. It means, for example, that if a Jacobian is estimated by finite differences, then the number of Jacobian evaluations will be zero and the number of function evaluations will be incremented by all calls during the finite difference estimation.

x
: [ndarray, shape (n,)] Solution found.

optimality
: [float] Infinity norm of the Lagrangian gradient at the solution.

constr_violation
: [float] Maximum constraint violation at the solution.

fun
: [float] Objective function at the solution.

grad
: [ndarray, shape (n,)] Gradient of the objective function at the solution.

lagrangian_grad
: [ndarray, shape (n,)] Gradient of the Lagrangian function at the solution.

nit
: [int] Total number of iterations.

nfev
: [integer] Number of the objective function evaluations.

njev [integer] Number of the objective function gradient evaluations.
nhev [integer] Number of the objective function Hessian evaluations.
cg_niter [int] Total number of the conjugate gradient method iterations.
method [{'equality_constrained_sqp', 'tr_interior_point'}] Optimization method used.
constr [list of ndarray] List of constraint values at the solution.
jac [list of {ndarray, sparse matrix}] List of the Jacobian matrices of the constraints at the solution.
v [list of ndarray] List of the Lagrange multipliers for the constraints at the solution. For an inequality constraint a positive multiplier means that the upper bound is active, a negative multiplier means that the lower bound is active and if a multiplier is zero it means the constraint is not active.
constr_nfev
[list of int] Number of constraint evaluations for each of the constraints.
constr_njev
[list of int] Number of Jacobian matrix evaluations for each of the constraints.
constr_nhev
[list of int] Number of Hessian evaluations for each of the constraints.
tr_radius [float] Radius of the trust region at the last iteration.
constr_penalty
[float] Penalty parameter at the last iteration, see *initial_constr_penalty*.
barrier_tolerance
[float] Tolerance for the barrier subproblem at the last iteration. Only for problems with inequality constraints.
barrier_parameter
[float] Barrier parameter at the last iteration. Only for problems with inequality constraints.
execution_time
[float] Total execution time.
message [str] Termination message.
status [{0, 1, 2, 3}] Termination status:
- 0 : The maximum number of function evaluations is exceeded.
- 1 : *gtol* termination condition is satisfied.
- 2 : *xtol* termination condition is satisfied.
- 3 : *callback* function requested termination.

cg_stop_cond
[int] Reason for CG subproblem termination at the last iteration:
- 0 : CG subproblem not evaluated.
- 1 : Iteration limit was reached.
- 2 : Reached the trust-region boundary.
- 3 : Negative curvature detected.
- 4 : Tolerance was satisfied.

Options

initial_tr_radius
[float] Initial trust-region radius.

max_tr_radius
[float] Maximum value of the trust-region radius. No steps that are longer than this value will be proposed.

eta [float] Trust region related acceptance stringency for proposed steps.

gtol [float] Gradient norm must be less than `gtol` before successful termination.

Constraints are passed to *minimize* function as a single object or as a list of objects from the following classes:

NonlinearConstraint(fun, lb, ub[, jac, …])	Nonlinear constraint on the variables.
LinearConstraint(A, lb, ub[, keep_feasible])	Linear constraint on the variables.

scipy.optimize.NonlinearConstraint

class scipy.optimize.**NonlinearConstraint**(*fun*, *lb*, *ub*, *jac='2-point'*, *hess=<scipy.optimize._hessian_update_strategy.BFGS object>*, *keep_feasible=False*, *finite_diff_rel_step=None*, *finite_diff_jac_sparsity=None*)

Nonlinear constraint on the variables.

The constraint has the general inequality form:

```
lb <= fun(x) <= ub
```

Here the vector of independent variables x is passed as ndarray of shape (n,) and `fun` returns a vector with m components.

It is possible to use equal bounds to represent an equality constraint or infinite bounds to represent a one-sided constraint.

Parameters

fun [callable] The function defining the constraint. The signature is `fun(x) -> array_like, shape (m,)`.

lb, ub [array_like] Lower and upper bounds on the constraint. Each array must have the shape (m,) or be a scalar, in the latter case a bound will be the same for all components of the constraint. Use `np.inf` with an appropriate sign to specify a one-sided constraint. Set components of *lb* and *ub* equal to represent an equality constraint. Note that you can mix constraints of

different types: interval, one-sided or equality, by setting different components of *lb* and *ub* as necessary.

jac [{callable, '2-point', '3-point', 'cs'}, optional] Method of computing the Jacobian matrix (an m-by-n matrix, where element (i, j) is the partial derivative of f[i] with respect to x[j]). The keywords {'2-point', '3-point', 'cs'} select a finite difference scheme for the numerical estimation. A callable must have the following signature: `jac(x) -> {ndarray, sparse matrix}, shape (m, n)`. Default is '2-point'.

hess [{callable, '2-point', '3-point', 'cs', HessianUpdateStrategy, None}, optional] Method for computing the Hessian matrix. The keywords {'2-point', '3-point', 'cs'} select a finite difference scheme for numerical estimation. Alternatively, objects implementing *HessianUpdateStrategy* interface can be used to approximate the Hessian. Currently available implementations are:

- *BFGS* (default option)
- *SR1*

A callable must return the Hessian matrix of `dot(fun, v)` and must have the following signature: `hess(x, v) -> {LinearOperator, sparse matrix, array_like}, shape (n, n)`. Here `v` is ndarray with shape (m,) containing Lagrange multipliers.

keep_feasible

[array_like of bool, optional] Whether to keep the constraint components feasible throughout iterations. A single value set this property for all components. Default is False. Has no effect for equality constraints.

finite_diff_rel_step: None or array_like, optional

Relative step size for the finite difference approximation. Default is None, which will select a reasonable value automatically depending on a finite difference scheme.

finite_diff_jac_sparsity: {None, array_like, sparse matrix}, optional

Defines the sparsity structure of the Jacobian matrix for finite difference estimation, its shape must be (m, n). If the Jacobian has only few non-zero elements in *each* row, providing the sparsity structure will greatly speed up the computations. A zero entry means that a corresponding element in the Jacobian is identically zero. If provided, forces the use of 'lsmr' trust-region solver. If None (default) then dense differencing will be used.

Notes

Finite difference schemes {'2-point', '3-point', 'cs'} may be used for approximating either the Jacobian or the Hessian. We, however, do not allow its use for approximating both simultaneously. Hence whenever the Jacobian is estimated via finite-differences, we require the Hessian to be estimated using one of the quasi-Newton strategies.

The scheme 'cs' is potentially the most accurate, but requires the function to correctly handles complex inputs and be analytically continuable to the complex plane. The scheme '3-point' is more accurate than '2-point' but requires twice as many operations.

Examples

Constrain `x[0] < sin(x[1]) + 1.9`

```
>>> from scipy.optimize import NonlinearConstraint
>>> con = lambda x: x[0] - np.sin(x[1])
>>> nlc = NonlinearConstraint(con, -np.inf, 1.9)
```

scipy.optimize.LinearConstraint

class scipy.optimize.**LinearConstraint**(*A*, *lb*, *ub*, *keep_feasible=False*)

Linear constraint on the variables.

The constraint has the general inequality form:

```
lb <= A.dot(x) <= ub
```

Here the vector of independent variables x is passed as ndarray of shape (n,) and the matrix A has shape (m, n).

It is possible to use equal bounds to represent an equality constraint or infinite bounds to represent a one-sided constraint.

Parameters

A [{array_like, sparse matrix}, shape (m, n)] Matrix defining the constraint.

lb, ub [array_like] Lower and upper bounds on the constraint. Each array must have the shape (m,) or be a scalar, in the latter case a bound will be the same for all components of the constraint. Use `np.inf` with an appropriate sign to specify a one-sided constraint. Set components of *lb* and *ub* equal to represent an equality constraint. Note that you can mix constraints of different types: interval, one-sided or equality, by setting different components of *lb* and *ub* as necessary.

keep_feasible [array_like of bool, optional] Whether to keep the constraint components feasible throughout iterations. A single value set this property for all components. Default is False. Has no effect for equality constraints.

Simple bound constraints are handled separately and there is a special class for them:

Bounds(lb, ub[, keep_feasible])	Bounds constraint on the variables.

scipy.optimize.Bounds

class scipy.optimize.**Bounds**(*lb*, *ub*, *keep_feasible=False*)

Bounds constraint on the variables.

The constraint has the general inequality form:

```
lb <= x <= ub
```

It is possible to use equal bounds to represent an equality constraint or infinite bounds to represent a one-sided constraint.

Parameters

lb, ub [array_like] Lower and upper bounds on independent variables. Each array must have the same size as x or be a scalar, in which case a bound will be the same for all the variables. Set components of *lb* and *ub* equal to fix a variable. Use `np.inf` with an appropriate sign to disable bounds on all or some variables. Note that you can mix constraints of different types: interval, one-sided or equality, by setting different components of *lb* and *ub* as necessary.

keep_feasible [array_like of bool, optional] Whether to keep the constraint components feasible throughout iterations. A single value set this property for all components. Default is False. Has no effect for equality constraints.

Quasi-Newton strategies implementing `HessianUpdateStrategy` interface can be used to approximate the Hessian in `minimize` function (available only for the 'trust-constr' method). Available quasi-Newton methods implementing this interface are:

`BFGS`([exception_strategy, min_curvature, …])	Broyden-Fletcher-Goldfarb-Shanno (BFGS) Hessian update strategy.
`SR1`([min_denominator, init_scale])	Symmetric-rank-1 Hessian update strategy.

scipy.optimize.BFGS

class scipy.optimize.**BFGS**(*exception_strategy='skip_update'*, *min_curvature=None*, *init_scale='auto'*)

Broyden-Fletcher-Goldfarb-Shanno (BFGS) Hessian update strategy.

Parameters

exception_strategy
: [{'skip_update', 'damp_update'}, optional] Define how to proceed when the curvature condition is violated. Set it to 'skip_update' to just skip the update. Or, alternatively, set it to 'damp_update' to interpolate between the actual BFGS result and the unmodified matrix. Both exceptions strategies are explained in [1], p.536-537.

min_curvature
: [float] This number, scaled by a normalization factor, defines the minimum curvature `dot(delta_grad, delta_x)` allowed to go unaffected by the exception strategy. By default is equal to 1e-8 when `exception_strategy = 'skip_update'` and equal to 0.2 when `exception_strategy = 'damp_update'`.

init_scale
: [{float, 'auto'}] Matrix scale at first iteration. At the first iteration the Hessian matrix or its inverse will be initialized with `init_scale*np.eye(n)`, where `n` is the problem dimension. Set it to 'auto' in order to use an automatic heuristic for choosing the initial scale. The heuristic is described in [1], p.143. By default uses 'auto'.

Notes

The update is based on the description in [1], p.140.

References

[1]

Methods

`dot`(p)	Compute the product of the internal matrix with the given vector.
`get_matrix`()	Return the current internal matrix.
`initialize`(n, approx_type)	Initialize internal matrix.
`update`(delta_x, delta_grad)	Update internal matrix.

scipy.optimize.BFGS.dot

BFGS.**dot**(*p*)

Compute the product of the internal matrix with the given vector.

Parameters

p [array_like] 1-D array representing a vector.

Returns

Hp [array] 1-D represents the result of multiplying the approximation matrix by vector p.

scipy.optimize.BFGS.get_matrix

BFGS.**get_matrix**()

Return the current internal matrix.

Returns

M [ndarray, shape (n, n)] Dense matrix containing either the Hessian or its inverse (depending on how *approx_type* was defined).

scipy.optimize.BFGS.initialize

BFGS.**initialize**(*n*, *approx_type*)

Initialize internal matrix.

Allocate internal memory for storing and updating the Hessian or its inverse.

Parameters

n [int] Problem dimension.

approx_type

[{'hess', 'inv_hess'}] Selects either the Hessian or the inverse Hessian. When set to 'hess' the Hessian will be stored and updated. When set to 'inv_hess' its inverse will be used instead.

scipy.optimize.BFGS.update

BFGS.**update**(*delta_x*, *delta_grad*)

Update internal matrix.

Update Hessian matrix or its inverse (depending on how 'approx_type' is defined) using information about the last evaluated points.

Parameters

delta_x [ndarray] The difference between two points the gradient function have been evaluated at: `delta_x = x2 - x1`.

delta_grad

[ndarray] The difference between the gradients: `delta_grad = grad(x2) - grad(x1)`.

scipy.optimize.SR1

class scipy.optimize.**SR1**(*min_denominator=1e-08*, *init_scale='auto'*)

Symmetric-rank-1 Hessian update strategy.

Parameters

min_denominator
: [float] This number, scaled by a normalization factor, defines the minimum denominator magnitude allowed in the update. When the condition is violated we skip the update. By default uses `1e-8`.

init_scale
: [{float, 'auto'}, optional] Matrix scale at first iteration. At the first iteration the Hessian matrix or its inverse will be initialized with `init_scale*np.eye(n)`, where `n` is the problem dimension. Set it to 'auto' in order to use an automatic heuristic for choosing the initial scale. The heuristic is described in [1], p.143. By default uses 'auto'.

Notes

The update is based on the description in [1], p.144-146.

dot(p)	Compute the product of the internal matrix with the given vector.
get_matrix()	Return the current internal matrix.
initialize(n, approx_type)	Initialize internal matrix.
update(delta_x, delta_grad)	Update internal matrix.

scipy.optimize.SR1.dot

SR1.**dot**(*p*)

Compute the product of the internal matrix with the given vector.

Parameters

p [array_like] 1-D array representing a vector.

Returns

Hp [array] 1-D represents the result of multiplying the approximation matrix by vector p.

scipy.optimize.SR1.get_matrix

SR1.**get_matrix**()
Return the current internal matrix.

Returns

M [ndarray, shape (n, n)] Dense matrix containing either the Hessian or its inverse (depending on how *approx_type* was defined).

scipy.optimize.SR1.initialize

SR1.**initialize**(*n*, *approx_type*)
Initialize internal matrix.

Allocate internal memory for storing and updating the Hessian or its inverse.

Parameters

n [int] Problem dimension.

approx_type
[{'hess', 'inv_hess'}] Selects either the Hessian or the inverse Hessian. When set to 'hess' the Hessian will be stored and updated. When set to 'inv_hess' its inverse will be used instead.

scipy.optimize.SR1.update

SR1.**update**(*delta_x*, *delta_grad*)
Update internal matrix.

Update Hessian matrix or its inverse (depending on how 'approx_type' is defined) using information about the last evaluated points.

Parameters

delta_x [ndarray] The difference between two points the gradient function have been evaluated at: `delta_x = x2 - x1`.

delta_grad
[ndarray] The difference between the gradients: `delta_grad = grad(x2) - grad(x1)`.

Global optimization

basinhopping(func, x0[, niter, T, stepsize, …])	Find the global minimum of a function using the basin-hopping algorithm.
brute(func, ranges[, args, Ns, full_output, …])	Minimize a function over a given range by brute force.
differential_evolution(func, bounds[, args, …])	Finds the global minimum of a multivariate function.
shgo(func, bounds[, args, constraints, n, …])	Finds the global minimum of a function using SHG optimization.
dual_annealing(func, bounds[, args, …])	Find the global minimum of a function using Dual Annealing.

scipy.optimize.basinhopping

scipy.optimize.**basinhopping**(*func*, *x0*, *niter=100*, *T=1.0*, *stepsize=0.5*, *minimizer_kwargs=None*, *take_step=None*, *accept_test=None*, *callback=None*, *interval=50*, *disp=False*, *niter_success=None*, *seed=None*)

Find the global minimum of a function using the basin-hopping algorithm.

Basin-hopping is a two-phase method that combines a global stepping algorithm with local minimization at each step. Designed to mimic the natural process of energy minimization of clusters of atoms, it works well for similar problems with "funnel-like, but rugged" energy landscapes [5].

As the step-taking, step acceptance, and minimization methods are all customizable, this function can also be used to implement other two-phase methods.

Parameters

func [callable `f(x, *args)`] Function to be optimized. `args` can be passed as an optional item in the dict `minimizer_kwargs`

x0 [array_like] Initial guess.

niter [integer, optional] The number of basin-hopping iterations. There will be a total of `niter + 1` runs of the local minimizer.

T [float, optional] The "temperature" parameter for the accept or reject criterion. Higher "temperatures" mean that larger jumps in function value will be accepted. For best results `T` should be comparable to the separation (in function value) between local minima.

stepsize [float, optional] Maximum step size for use in the random displacement.

minimizer_kwargs [dict, optional] Extra keyword arguments to be passed to the local minimizer `scipy.optimize.minimize()` Some important options could be:

- **method** [str] The minimization method (e.g. `"L-BFGS-B"`)
- **args** [tuple] Extra arguments passed to the objective function (`func`) and its derivatives (Jacobian, Hessian).

take_step [callable `take_step(x)`, optional] Replace the default step-taking routine with this routine. The default step-taking routine is a random displacement of the coordinates, but other step-taking algorithms may be better for some systems. `take_step` can optionally have the attribute `take_step.stepsize`. If this attribute exists, then `basinhopping` will adjust `take_step.stepsize` in order to try to optimize the global minimum search.

accept_test [callable, `accept_test(f_new=f_new, x_new=x_new, f_old=fold, x_old=x_old)`, optional] Define a test which will be used to judge whether or not to accept the step. This will be used in addition to the Metropolis test based on "temperature" `T`. The acceptable return values are True, False, or `"force accept"`. If any of the tests return False then the step is rejected. If the latter, then this will override any other tests in order to accept the step. This can be used, for example, to forcefully escape from a local minimum that `basinhopping` is trapped in.

callback [callable, `callback(x, f, accept)`, optional] A callback function which will be called for all minima found. `x` and `f` are the coordinates and function value of the trial minimum, and `accept` is whether or not that minimum was accepted. This can be used, for example, to save the lowest N minima found. Also, `callback` can be used to specify a user defined stop criterion by optionally returning True to stop the `basinhopping` routine.

interval [integer, optional] interval for how often to update the `stepsize`

disp [bool, optional] Set to True to print status messages

niter_success [integer, optional] Stop the run if the global minimum candidate remains the same for this number of iterations.

seed [{None, int, `numpy.random.Generator`,] `numpy.random.RandomState`}, optional

If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used. Specify *seed* for repeatable minimizations. The random numbers generated with this seed only affect the default Metropolis *accept_test* and the default *take_step*. If you supply your own *take_step* and *accept_test*, and these functions use random number generation, then those functions are responsible for the state of their random number generator.

Returns

res [OptimizeResult] The optimization result represented as a `OptimizeResult` object. Important attributes are: `x` the solution array, `fun` the value of the function at the solution, and `message` which describes the cause of the termination. The `OptimizeResult` object returned by the selected minimizer at the lowest minimum is also contained within this object and can be accessed through the `lowest_optimization_result` attribute. See *`OptimizeResult`* for a description of other attributes.

See also:

`minimize`

The local minimization function called once for each basinhopping step. `minimizer_kwargs` is passed to this routine.

Notes

Basin-hopping is a stochastic algorithm which attempts to find the global minimum of a smooth scalar function of one or more variables [1] [2] [3] [4]. The algorithm in its current form was described by David Wales and Jonathan Doye [2] http://www-wales.ch.cam.ac.uk/.

The algorithm is iterative with each cycle composed of the following features

1) random perturbation of the coordinates

2) local minimization

3) accept or reject the new coordinates based on the minimized function value

The acceptance test used here is the Metropolis criterion of standard Monte Carlo algorithms, although there are many other possibilities [3].

This global minimization method has been shown to be extremely efficient for a wide variety of problems in physics and chemistry. It is particularly useful when the function has many minima separated by large barriers. See the Cambridge Cluster Database http://www-wales.ch.cam.ac.uk/CCD.html for databases of molecular systems that have been optimized primarily using basin-hopping. This database includes minimization problems exceeding 300 degrees of freedom.

See the free software program GMIN (http://www-wales.ch.cam.ac.uk/GMIN) for a Fortran implementation of basin-hopping. This implementation has many different variations of the procedure described above, including more advanced step taking algorithms and alternate acceptance criterion.

For stochastic global optimization there is no way to determine if the true global minimum has actually been found. Instead, as a consistency check, the algorithm can be run from a number of different random starting points to ensure the lowest minimum found in each example has converged to the global minimum. For this reason, `basinhopping` will by default simply run for the number of iterations `niter` and return the lowest minimum found. It is left to the user to ensure that this is in fact the global minimum.

Choosing `stepsize`: This is a crucial parameter in `basinhopping` and depends on the problem being solved. The step is chosen uniformly in the region from x0-stepsize to x0+stepsize, in each dimension. Ideally, it should be comparable to the typical separation (in argument values) between local minima of the function being optimized.

`basinhopping` will, by default, adjust `stepsize` to find an optimal value, but this may take many iterations. You will get quicker results if you set a sensible initial value for `stepsize`.

Choosing `T`: The parameter `T` is the "temperature" used in the Metropolis criterion. Basinhopping steps are always accepted if `func(xnew) < func(xold)`. Otherwise, they are accepted with probability:

```
exp( -(func(xnew) - func(xold)) / T )
```

So, for best results, `T` should to be comparable to the typical difference (in function values) between local minima. (The height of "walls" between local minima is irrelevant.)

If `T` is 0, the algorithm becomes Monotonic Basin-Hopping, in which all steps that increase energy are rejected.

New in version 0.12.0.

[1], [2], [3], [4], [5]

Examples

The following example is a 1-D minimization problem, with many local minima superimposed on a parabola.

```
>>> from scipy.optimize import basinhopping
>>> func = lambda x: np.cos(14.5 * x - 0.3) + (x + 0.2) * x
>>> x0=[1.]
```

Basinhopping, internally, uses a local minimization algorithm. We will use the parameter `minimizer_kwargs` to tell basinhopping which algorithm to use and how to set up that minimizer. This parameter will be passed to `scipy.optimize.minimize()`.

```
>>> minimizer_kwargs = {"method": "BFGS"}
>>> ret = basinhopping(func, x0, minimizer_kwargs=minimizer_kwargs,
...                    niter=200)
>>> print("global minimum: x = %.4f, f(x0) = %.4f" % (ret.x, ret.fun))
global minimum: x = -0.1951, f(x0) = -1.0009
```

Next consider a 2-D minimization problem. Also, this time, we will use gradient information to significantly speed up the search.

```
>>> def func2d(x):
...     f = np.cos(14.5 * x[0] - 0.3) + (x[1] + 0.2) * x[1] + (x[0] +
...                                                             0.2) * x[0]
...     df = np.zeros(2)
...     df[0] = -14.5 * np.sin(14.5 * x[0] - 0.3) + 2. * x[0] + 0.2
...     df[1] = 2. * x[1] + 0.2
...     return f, df
```

We'll also use a different local minimization algorithm. Also, we must tell the minimizer that our function returns both energy and gradient (Jacobian).

```
>>> minimizer_kwargs = {"method":"L-BFGS-B", "jac":True}
>>> x0 = [1.0, 1.0]
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
```

(continues on next page)

(continued from previous page)

```
...                       niter=200)
>>> print("global minimum: x = [%.4f, %.4f], f(x0) = %.4f" % (ret.x[0],
...                                                          ret.x[1],
...                                                          ret.fun))
global minimum: x = [-0.1951, -0.1000], f(x0) = -1.0109
```

Here is an example using a custom step-taking routine. Imagine you want the first coordinate to take larger steps than the rest of the coordinates. This can be implemented like so:

```
>>> class MyTakeStep:
...     def __init__(self, stepsize=0.5):
...         self.stepsize = stepsize
...         self.rng = np.random.default_rng()
...     def __call__(self, x):
...         s = self.stepsize
...         x[0] += self.rng.uniform(-2.*s, 2.*s)
...         x[1:] += self.rng.uniform(-s, s, x[1:].shape)
...         return x
```

Since `MyTakeStep.stepsize` exists basinhopping will adjust the magnitude of `stepsize` to optimize the search. We'll use the same 2-D function as before

```
>>> mytakestep = MyTakeStep()
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...                    niter=200, take_step=mytakestep)
>>> print("global minimum: x = [%.4f, %.4f], f(x0) = %.4f" % (ret.x[0],
...                                                          ret.x[1],
...                                                          ret.fun))
global minimum: x = [-0.1951, -0.1000], f(x0) = -1.0109
```

Now, let's do an example using a custom callback function which prints the value of every minimum found

```
>>> def print_fun(x, f, accepted):
...         print("at minimum %.4f accepted %d" % (f, int(accepted)))
```

We'll run it for only 10 basinhopping steps this time.

```
>>> rng = np.random.default_rng()
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...                    niter=10, callback=print_fun, seed=rng)
at minimum 0.4159 accepted 1
at minimum -0.4317 accepted 1
at minimum -1.0109 accepted 1
at minimum -0.9073 accepted 1
at minimum -0.4317 accepted 0
at minimum -0.1021 accepted 1
at minimum -0.7425 accepted 1
at minimum -0.9073 accepted 1
at minimum -0.4317 accepted 0
at minimum -0.7425 accepted 1
at minimum -0.9073 accepted 1
```

The minimum at -1.0109 is actually the global minimum, found already on the 8th iteration.

Now let's implement bounds on the problem using a custom `accept_test`:

```
>>> class MyBounds:
...     def __init__(self, xmax=[1.1,1.1], xmin=[-1.1,-1.1] ):
...         self.xmax = np.array(xmax)
...         self.xmin = np.array(xmin)
...     def __call__(self, **kwargs):
...         x = kwargs["x_new"]
...         tmax = bool(np.all(x <= self.xmax))
...         tmin = bool(np.all(x >= self.xmin))
...         return tmax and tmin
```

```
>>> mybounds = MyBounds()
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...                    niter=10, accept_test=mybounds)
```

scipy.optimize.brute

scipy.optimize.**brute**(*func*, *ranges*, *args=()*, *Ns=20*, *full_output=0*, *finish=<function fmin>*, *disp=False*, *workers=1*)

Minimize a function over a given range by brute force.

Uses the "brute force" method, i.e., computes the function's value at each point of a multidimensional grid of points, to find the global minimum of the function.

The function is evaluated everywhere in the range with the datatype of the first call to the function, as enforced by the `vectorize` NumPy function. The value and type of the function evaluation returned when `full_output=True` are affected in addition by the `finish` argument (see Notes).

The brute force approach is inefficient because the number of grid points increases exponentially - the number of grid points to evaluate is `Ns ** len(x)`. Consequently, even with coarse grid spacing, even moderately sized problems can take a long time to run, and/or run into memory limitations.

Parameters

func [callable] The objective function to be minimized. Must be in the form `f(x, *args)`, where `x` is the argument in the form of a 1-D array and `args` is a tuple of any additional fixed parameters needed to completely specify the function.

ranges [tuple] Each component of the *ranges* tuple must be either a "slice object" or a range tuple of the form `(low, high)`. The program uses these to create the grid of points on which the objective function will be computed. See *Note 2* for more detail.

args [tuple, optional] Any additional fixed parameters needed to completely specify the function.

Ns [int, optional] Number of grid points along the axes, if not otherwise specified. See *Note2*.

full_output [bool, optional] If True, return the evaluation grid and the objective function's values on it.

finish [callable, optional] An optimization function that is called with the result of brute force minimization as initial guess. *finish* should take *func* and the initial guess as positional arguments, and take *args* as keyword arguments. It may additionally take *full_output* and/or *disp* as keyword arguments. Use None if no "polishing" function is to be used. See Notes for more details.

disp [bool, optional] Set to True to print convergence messages from the *finish* callable.

workers [int or map-like callable, optional] If *workers* is an int the grid is subdivided into *workers* sections and evaluated in parallel (uses `multiprocessing.Pool`). Supply *-1* to use

all cores available to the Process. Alternatively supply a map-like callable, such as *multiprocessing.Pool.map* for evaluating the grid in parallel. This evaluation is carried out as `workers(func, iterable)`. Requires that *func* be pickleable.
New in version 1.3.0.

Returns

x0 [ndarray] A 1-D array containing the coordinates of a point at which the objective function had its minimum value. (See *Note 1* for which point is returned.)

fval [float] Function value at the point *x0*. (Returned when *full_output* is True.)

grid [tuple] Representation of the evaluation grid. It has the same length as *x0*. (Returned when *full_output* is True.)

Jout [ndarray] Function values at each point of the evaluation grid, i.e., `Jout = func(*grid)`. (Returned when *full_output* is True.)

See also:

basinhopping, **differential_evolution**

Notes

Note 1: The program finds the gridpoint at which the lowest value of the objective function occurs. If *finish* is None, that is the point returned. When the global minimum occurs within (or not very far outside) the grid's boundaries, and the grid is fine enough, that point will be in the neighborhood of the global minimum.

However, users often employ some other optimization program to "polish" the gridpoint values, i.e., to seek a more precise (local) minimum near *brute's* best gridpoint. The *brute* function's *finish* option provides a convenient way to do that. Any polishing program used must take *brute's* output as its initial guess as a positional argument, and take *brute's* input values for *args* as keyword arguments, otherwise an error will be raised. It may additionally take *full_output* and/or *disp* as keyword arguments.

brute assumes that the *finish* function returns either an *OptimizeResult* object or a tuple in the form: `(xmin, Jmin, ... , statuscode)`, where `xmin` is the minimizing value of the argument, `Jmin` is the minimum value of the objective function, "..." may be some other returned values (which are not used by *brute*), and `statuscode` is the status code of the *finish* program.

Note that when *finish* is not None, the values returned are those of the *finish* program, *not* the gridpoint ones. Consequently, while *brute* confines its search to the input grid points, the *finish* program's results usually will not coincide with any gridpoint, and may fall outside the grid's boundary. Thus, if a minimum only needs to be found over the provided grid points, make sure to pass in *finish=None*.

Note 2: The grid of points is a `numpy.mgrid` object. For *brute* the *ranges* and *Ns* inputs have the following effect. Each component of the *ranges* tuple can be either a slice object or a two-tuple giving a range of values, such as (0, 5). If the component is a slice object, *brute* uses it directly. If the component is a two-tuple range, *brute* internally converts it to a slice object that interpolates *Ns* points from its low-value to its high-value, inclusive.

Examples

We illustrate the use of *brute* to seek the global minimum of a function of two variables that is given as the sum of a positive-definite quadratic and two deep "Gaussian-shaped" craters. Specifically, define the objective function *f* as the sum of three other functions, `f = f1 + f2 + f3`. We suppose each of these has a signature `(z, *params)`, where `z = (x, y)`, and `params` and the functions are as defined below.

```
>>> params = (2, 3, 7, 8, 9, 10, 44, -1, 2, 26, 1, -2, 0.5)
>>> def f1(z, *params):
...     x, y = z
...     a, b, c, d, e, f, g, h, i, j, k, l, scale = params
...     return (a * x**2 + b * x * y + c * y**2 + d*x + e*y + f)
```

```
>>> def f2(z, *params):
...     x, y = z
...     a, b, c, d, e, f, g, h, i, j, k, l, scale = params
...     return (-g*np.exp(-((x-h)**2 + (y-i)**2) / scale))
```

```
>>> def f3(z, *params):
...     x, y = z
...     a, b, c, d, e, f, g, h, i, j, k, l, scale = params
...     return (-j*np.exp(-((x-k)**2 + (y-l)**2) / scale))
```

```
>>> def f(z, *params):
...     return f1(z, *params) + f2(z, *params) + f3(z, *params)
```

Thus, the objective function may have local minima near the minimum of each of the three functions of which it is composed. To use *fmin* to polish its gridpoint result, we may then continue as follows:

```
>>> rranges = (slice(-4, 4, 0.25), slice(-4, 4, 0.25))
>>> from scipy import optimize
>>> resbrute = optimize.brute(f, rranges, args=params, full_output=True,
...                           finish=optimize.fmin)
>>> resbrute[0]  # global minimum
array([-1.05665192,  1.80834843])
>>> resbrute[1]  # function value at global minimum
-3.4085818767
```

Note that if *finish* had been set to None, we would have gotten the gridpoint [-1.0 1.75] where the rounded function value is -2.892.

scipy.optimize.differential_evolution

scipy.optimize.**differential_evolution**(*func*, *bounds*, *args=()*, *strategy='best1bin'*, *maxiter=1000*, *popsize=15*, *tol=0.01*, *mutation=(0.5, 1)*, *recombination=0.7*, *seed=None*, *callback=None*, *disp=False*, *polish=True*, *init='latinhypercube'*, *atol=0*, *updating='immediate'*, *workers=1*, *constraints=()*, *x0=None*)

Finds the global minimum of a multivariate function.

Differential Evolution is stochastic in nature (does not use gradient methods) to find the minimum, and can search

large areas of candidate space, but often requires larger numbers of function evaluations than conventional gradient-based techniques.

The algorithm is due to Storn and Price [1].

Parameters

func [callable] The objective function to be minimized. Must be in the form `f(x, *args)`, where `x` is the argument in the form of a 1-D array and `args` is a tuple of any additional fixed parameters needed to completely specify the function.

bounds [sequence or *Bounds*] Bounds for variables. There are two ways to specify the bounds: 1. Instance of *Bounds* class. 2. `(min, max)` pairs for each element in `x`, defining the finite lower and upper bounds for the optimizing argument of *func*. It is required to have `len(bounds) == len(x)`. `len(bounds)` is used to determine the number of parameters in `x`.

args [tuple, optional] Any additional fixed parameters needed to completely specify the objective function.

strategy [str, optional] The differential evolution strategy to use. Should be one of:

- 'best1bin'
- 'best1exp'
- 'rand1exp'
- 'randtobest1exp'
- 'currenttobest1exp'
- 'best2exp'
- 'rand2exp'
- 'randtobest1bin'
- 'currenttobest1bin'
- 'best2bin'
- 'rand2bin'
- 'rand1bin'

The default is 'best1bin'.

maxiter [int, optional] The maximum number of generations over which the entire population is evolved. The maximum number of function evaluations (with no polishing) is: `(maxiter + 1) * popsize * len(x)`

popsize [int, optional] A multiplier for setting the total population size. The population has `popsize * len(x)` individuals. This keyword is overridden if an initial population is supplied via the *init* keyword. When using `init='sobol'` the population size is calculated as the next power of 2 after `popsize * len(x)`.

tol [float, optional] Relative tolerance for convergence, the solving stops when `np.std(pop) <= atol + tol * np.abs(np.mean(population_energies))`, where and *atol* and *tol* are the absolute and relative tolerance respectively.

mutation [float or tuple(float, float), optional] The mutation constant. In the literature this is also known as differential weight, being denoted by F. If specified as a float it should be in the range [0, 2]. If specified as a tuple `(min, max)` dithering is employed. Dithering randomly changes the mutation constant on a generation by generation basis. The mutation constant for that generation is taken from `U[min, max)`. Dithering can help speed convergence significantly. Increasing the mutation constant increases the search radius, but will slow down convergence.

recombination [float, optional] The recombination constant, should be in the range [0, 1]. In the literature this is also known as the crossover probability, being denoted by CR. Increasing this value allows a larger number of mutants to progress into the next generation, but at the risk of population stability.

seed [{None, int, `numpy.random.Generator`,] `numpy.random.RandomState`}, optional

If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used. Specify *seed* for repeatable minimizations.

disp [bool, optional] Prints the evaluated *func* at every iteration.

callback [callable, *callback(xk, convergence=val)*, optional] A function to follow the progress of the minimization. `xk` is the current value of `x0`. `val` represents the fractional value of the population convergence. When `val` is greater than one the function halts. If callback returns *True*, then the minimization is halted (any polishing is still carried out).

polish [bool, optional] If True (default), then *scipy.optimize.minimize* with the *L-BFGS-B* method is used to polish the best population member at the end, which can improve the minimization slightly. If a constrained problem is being studied then the *trust-constr* method is used instead.

init [str or array-like, optional] Specify which type of population initialization is performed. Should be one of:

- 'latinhypercube'
- 'sobol'
- 'halton'
- 'random'
- array specifying the initial population. The array should have shape `(M, len(x))`, where M is the total population size and len(x) is the number of parameters. *init* is clipped to *bounds* before use.

The default is 'latinhypercube'. Latin Hypercube sampling tries to maximize coverage of the available parameter space.

'sobol' and 'halton' are superior alternatives and maximize even more the parameter space. 'sobol' will enforce an initial population size which is calculated as the next power of 2 after `popsize * len(x)`. 'halton' has no requirements but is a bit less efficient. See *scipy.stats.qmc* for more details.

'random' initializes the population randomly - this has the drawback that clustering can occur, preventing the whole of parameter space being covered. Use of an array to specify a population could be used, for example, to create a tight bunch of initial guesses in an location where the solution is known to exist, thereby reducing time for convergence.

atol [float, optional] Absolute tolerance for convergence, the solving stops when `np.std(pop) <= atol + tol * np.abs(np.mean(population_energies))`, where and *atol* and *tol* are the absolute and relative tolerance respectively.

updating [{'immediate', 'deferred'}, optional] If `'immediate'`, the best solution vector is continuously updated within a single generation [4]. This can lead to faster convergence as trial vectors can take advantage of continuous improvements in the best solution. With `'deferred'`, the best solution vector is updated once per generation. Only `'deferred'` is compatible with parallelization, and the *workers* keyword can over-ride this option.

New in version 1.2.0.

workers [int or map-like callable, optional] If *workers* is an int the population is subdivided into *workers* sections and evaluated in parallel (uses `multiprocessing.Pool`). Supply -1 to use all available CPU cores. Alternatively supply a map-like callable, such as *multiprocessing.Pool.map* for evaluating the population in parallel. This evaluation is carried out as `workers(func, iterable)`. This option will override the *updating* keyword to `updating='deferred'` if `workers != 1`. Requires that *func* be pickleable.

New in version 1.2.0.

constraints [{NonLinearConstraint, LinearConstraint, Bounds}] Constraints on the solver, over and above those applied by the *bounds* kwd. Uses the approach by Lampinen [5].

New in version 1.4.0.

x0 [None or array-like, optional] Provides an initial guess to the minimization. Once the population has been initialized this vector replaces the first (best) member. This replacement is

done even if *init* is given an initial population.
New in version 1.7.0.

Returns

res [OptimizeResult] The optimization result represented as a `OptimizeResult` object. Important attributes are: `x` the solution array, `success` a Boolean flag indicating if the optimizer exited successfully and `message` which describes the cause of the termination. See `OptimizeResult` for a description of other attributes. If *polish* was employed, and a lower minimum was obtained by the polishing, then OptimizeResult also contains the `jac` attribute. If the eventual solution does not satisfy the applied constraints `success` will be *False*.

Notes

Differential evolution is a stochastic population based method that is useful for global optimization problems. At each pass through the population the algorithm mutates each candidate solution by mixing with other candidate solutions to create a trial candidate. There are several strategies [2] for creating trial candidates, which suit some problems more than others. The 'best1bin' strategy is a good starting point for many systems. In this strategy two members of the population are randomly chosen. Their difference is used to mutate the best member (the 'best' in 'best1bin'), b_0, so far:

$$b' = b_0 + mutation * (population[rand0] - population[rand1])$$

A trial vector is then constructed. Starting with a randomly chosen ith parameter the trial is sequentially filled (in modulo) with parameters from `b'` or the original candidate. The choice of whether to use `b'` or the original candidate is made with a binomial distribution (the 'bin' in 'best1bin') - a random number in [0, 1) is generated. If this number is less than the *recombination* constant then the parameter is loaded from `b'`, otherwise it is loaded from the original candidate. The final parameter is always loaded from `b'`. Once the trial candidate is built its fitness is assessed. If the trial is better than the original candidate then it takes its place. If it is also better than the best overall candidate it also replaces that. To improve your chances of finding a global minimum use higher *popsize* values, with higher *mutation* and (dithering), but lower *recombination* values. This has the effect of widening the search radius, but slowing convergence. By default the best solution vector is updated continuously within a single iteration (`updating='immediate'`). This is a modification [4] of the original differential evolution algorithm which can lead to faster convergence as trial vectors can immediately benefit from improved solutions. To use the original Storn and Price behaviour, updating the best solution once per iteration, set `updating='deferred'`.

New in version 0.15.0.

Examples

Let us consider the problem of minimizing the Rosenbrock function. This function is implemented in `rosen` in `scipy.optimize`.

```
>>> from scipy.optimize import rosen, differential_evolution
>>> bounds = [(0,2), (0, 2), (0, 2), (0, 2), (0, 2)]
>>> result = differential_evolution(rosen, bounds)
>>> result.x, result.fun
(array([1., 1., 1., 1., 1.]), 1.9216496320061384e-19)
```

Now repeat, but with parallelization.

```
>>> bounds = [(0,2), (0, 2), (0, 2), (0, 2), (0, 2)]
>>> result = differential_evolution(rosen, bounds, updating='deferred',
...                                 workers=2)
>>> result.x, result.fun
(array([1., 1., 1., 1., 1.]), 1.9216496320061384e-19)
```

Let's try and do a constrained minimization

```
>>> from scipy.optimize import NonlinearConstraint, Bounds
>>> def constr_f(x):
...     return np.array(x[0] + x[1])
>>>
>>> # the sum of x[0] and x[1] must be less than 1.9
>>> nlc = NonlinearConstraint(constr_f, -np.inf, 1.9)
>>> # specify limits using a `Bounds` object.
>>> bounds = Bounds([0., 0.], [2., 2.])
>>> result = differential_evolution(rosen, bounds, constraints=(nlc),
...                                 seed=1)
>>> result.x, result.fun
(array([0.96633867, 0.93363577]), 0.0011361355854792312)
```

Next find the minimum of the Ackley function (https://en.wikipedia.org/wiki/Test_functions_for_optimization).

```
>>> from scipy.optimize import differential_evolution
>>> import numpy as np
>>> def ackley(x):
...     arg1 = -0.2 * np.sqrt(0.5 * (x[0] ** 2 + x[1] ** 2))
...     arg2 = 0.5 * (np.cos(2. * np.pi * x[0]) + np.cos(2. * np.pi *␣
↪x[1]))
...     return -20. * np.exp(arg1) - np.exp(arg2) + 20. + np.e
>>> bounds = [(-5, 5), (-5, 5)]
>>> result = differential_evolution(ackley, bounds)
>>> result.x, result.fun
(array([ 0.,  0.]), 4.440892098500626e-16)
```

scipy.optimize.shgo

scipy.optimize.**shgo**(*func*, *bounds*, *args=()*, *constraints=None*, *n=None*, *iters=1*, *callback=None*, *minimizer_kwargs=None*, *options=None*, *sampling_method='simplicial'*)

Finds the global minimum of a function using SHG optimization.

SHGO stands for "simplicial homology global optimization".

Parameters

func [callable] The objective function to be minimized. Must be in the form `f(x, *args)`, where `x` is the argument in the form of a 1-D array and `args` is a tuple of any additional fixed parameters needed to completely specify the function.

bounds [sequence] Bounds for variables. `(min, max)` pairs for each element in `x`, defining the lower and upper bounds for the optimizing argument of *func*. It is required to have `len(bounds) == len(x)`. `len(bounds)` is used to determine the number of parameters in `x`. Use `None` for one of min or max when there is no bound in that direction. By default bounds are `(None, None)`.

args [tuple, optional] Any additional fixed parameters needed to completely specify the objective function.

constraints

[dict or sequence of dict, optional] Constraints definition. Function(s) `R**n` in the form:

```
g(x) >= 0 applied as g : R^n -> R^m
h(x) == 0 applied as h : R^n -> R^p
```

Each constraint is defined in a dictionary with fields:

- **type** [str] Constraint type: 'eq' for equality, 'ineq' for inequality.
- **fun** [callable] The function defining the constraint.
- **jac** [callable, optional] The Jacobian of *fun* (only for SLSQP).
- **args** [sequence, optional] Extra arguments to be passed to the function and Jacobian.

Equality constraint means that the constraint function result is to be zero whereas inequality means that it is to be non-negative. Note that COBYLA only supports inequality constraints.

Note: Only the COBYLA and SLSQP local minimize methods currently support constraint arguments. If the `constraints` sequence used in the local optimization problem is not defined in `minimizer_kwargs` and a constrained method is used then the global `constraints` will be used. (Defining a `constraints` sequence in `minimizer_kwargs` means that `constraints` will not be added so if equality constraints and so forth need to be added then the inequality functions in `constraints` need to be added to `minimizer_kwargs` too).

---

n [int, optional] Number of sampling points used in the construction of the simplicial complex. Note that this argument is only used for `sobol` and other arbitrary *sampling_methods*. In case of `sobol`, it must be a power of 2: `n=2**m`, and the argument will automatically be converted to the next higher power of 2. Default is 100 for `sampling_method='simplicial'` and 128 for `sampling_method='sobol'`.

iters [int, optional] Number of iterations used in the construction of the simplicial complex. Default is 1.

callback [callable, optional] Called after each iteration, as `callback(xk)`, where `xk` is the current parameter vector.

minimizer_kwargs

[dict, optional] Extra keyword arguments to be passed to the minimizer `scipy.optimize.minimize` Some important options could be:

- **method** [str] The minimization method, the default is `SLSQP`.
- **args** [tuple] Extra arguments passed to the objective function (`func`) and its derivatives (Jacobian, Hessian).
- **options** [dict, optional] Note that by default the tolerance is specified as `{ftol: 1e-12}`

options [dict, optional] A dictionary of solver options. Many of the options specified for the global routine are also passed to the scipy.optimize.minimize routine. The options that are also passed to the local routine are marked with "(L)".

Stopping criteria, the algorithm will terminate if any of the specified criteria are met. However, the default algorithm does not require any to be specified:

- **maxfev** [int (L)] Maximum number of function evaluations in the feasible domain. (Note only methods that support this option will terminate the routine at precisely exact specified value. Otherwise the criterion will only terminate during a global iteration)
- **f_min** Specify the minimum objective function value, if it is known.
- **f_tol** [float] Precision goal for the value of f in the stopping criterion. Note that the global routine will also terminate if a sampling point in the global routine is within this tolerance.

- **maxiter** [int] Maximum number of iterations to perform.
- **maxev** [int] Maximum number of sampling evaluations to perform (includes searching in infeasible points).
- **maxtime** [float] Maximum processing runtime allowed
- **minhgrd** [int] Minimum homology group rank differential. The homology group of the objective function is calculated (approximately) during every iteration. The rank of this group has a one-to-one correspondence with the number of locally convex subdomains in the objective function (after adequate sampling points each of these subdomains contain a unique global minimum). If the difference in the hgr is 0 between iterations for `maxhgrd` specified iterations the algorithm will terminate.

Objective function knowledge:

- **symmetry** [bool] Specify True if the objective function contains symmetric variables. The search space (and therefore performance) is decreased by O(n!).
- **jac** [bool or callable, optional] Jacobian (gradient) of objective function. Only for CG, BFGS, Newton-CG, L-BFGS-B, TNC, SLSQP, dogleg, trust-ncg. If `jac` is a boolean and is True, `fun` is assumed to return the gradient along with the objective function. If False, the gradient will be estimated numerically. `jac` can also be a callable returning the gradient of the objective. In this case, it must accept the same arguments as `fun`. (Passed to *scipy.optimize.minmize* automatically)
- **hess, hessp** [callable, optional] Hessian (matrix of second-order derivatives) of objective function or Hessian of objective function times an arbitrary vector p. Only for Newton-CG, dogleg, trust-ncg. Only one of `hessp` or `hess` needs to be given. If `hess` is provided, then `hessp` will be ignored. If neither `hess` nor `hessp` is provided, then the Hessian product will be approximated using finite differences on `jac`. `hessp` must compute the Hessian times an arbitrary vector. (Passed to *scipy.optimize.minmize* automatically)

Algorithm settings:

- **minimize_every_iter** [bool] If True then promising global sampling points will be passed to a local minimization routine every iteration. If False then only the final minimizer pool will be run. Defaults to False.
- **local_iter** [int] Only evaluate a few of the best minimizer pool candidates every iteration. If False all potential points are passed to the local minimization routine.
- **infty_constraints: bool** If True then any sampling points generated which are outside will the feasible domain will be saved and given an objective function value of `inf`. If False then these points will be discarded. Using this functionality could lead to higher performance with respect to function evaluations before the global minimum is found, specifying False will use less memory at the cost of a slight decrease in performance. Defaults to True.

Feedback:

- **disp** [bool (L)] Set to True to print convergence messages.

sampling_method

[str or function, optional] Current built in sampling method options are `halton`, `sobol` and `simplicial`. The default `simplicial` provides the theoretical guarantee of convergence to the global minimum in finite time. `halton` and `sobol` method are faster in terms of sampling point generation at the cost of the loss of guaranteed convergence. It is more appropriate for most "easier" problems where the convergence is relatively fast. User defined sampling functions must accept two arguments of `n` sampling points of dimension `dim` per call and output an array of sampling points with shape *n x dim*.

Returns

res [OptimizeResult] The optimization result represented as a *OptimizeResult* object. Important attributes are: `x` the solution array corresponding to the global minimum, `fun` the function output at the global solution, `xl` an ordered list of local minima solutions, `funl` the function output at the corresponding local solutions, `success` a Boolean flag indicating if the optimizer exited successfully, `message` which describes the cause of the termination, `nfev` the total number of objective function evaluations including the sampling calls, `nlfev` the total number of objective function evaluations culminating from all local search optimizations, `nit` number of iterations performed by the global routine.

Notes

Global optimization using simplicial homology global optimization [1]. Appropriate for solving general purpose NLP and blackbox optimization problems to global optimality (low-dimensional problems).

In general, the optimization problems are of the form:

```
minimize f(x) subject to

g_i(x) >= 0,  i = 1,...,m
h_j(x)  = 0,  j = 1,...,p
```

where x is a vector of one or more variables. `f(x)` is the objective function `R^n -> R`, `g_i(x)` are the inequality constraints, and `h_j(x)` are the equality constraints.

Optionally, the lower and upper bounds for each element in x can also be specified using the *bounds* argument.

While most of the theoretical advantages of SHGO are only proven for when `f(x)` is a Lipschitz smooth function, the algorithm is also proven to converge to the global optimum for the more general case where `f(x)` is non-continuous, non-convex and non-smooth, if the default sampling method is used [1].

The local search method may be specified using the `minimizer_kwargs` parameter which is passed on to `scipy.optimize.minimize`. By default, the `SLSQP` method is used. In general, it is recommended to use the `SLSQP` or `COBYLA` local minimization if inequality constraints are defined for the problem since the other methods do not use constraints.

The `halton` and `sobol` method points are generated using *scipy.stats.qmc*. Any other QMC method could be used.

Examples

First consider the problem of minimizing the Rosenbrock function, *rosen*:

```
>>> from scipy.optimize import rosen, shgo
>>> bounds = [(0,2), (0, 2), (0, 2), (0, 2), (0, 2)]
>>> result = shgo(rosen, bounds)
>>> result.x, result.fun
(array([1., 1., 1., 1., 1.]), 2.920392374190081e-18)
```

Note that bounds determine the dimensionality of the objective function and is therefore a required input, however you can specify empty bounds using `None` or objects like `np.inf` which will be converted to large float numbers.

```
>>> bounds = [(None, None), ]*4
>>> result = shgo(rosen, bounds)
>>> result.x
array([0.99999851, 0.99999704, 0.99999411, 0.9999882 ])
```

Next, we consider the Eggholder function, a problem with several local minima and one global minimum. We will demonstrate the use of arguments and the capabilities of *shgo*. (https://en.wikipedia.org/wiki/Test_functions_for_optimization)

```
>>> def eggholder(x):
...     return (-(x[1] + 47.0)
...             * np.sin(np.sqrt(abs(x[0]/2.0 + (x[1] + 47.0))))
...             - x[0] * np.sin(np.sqrt(abs(x[0] - (x[1] + 47.0))))
...             )
...
>>> bounds = [(-512, 512), (-512, 512)]
```

shgo has built-in low discrepancy sampling sequences. First, we will input 64 initial sampling points of the *Sobol'* sequence:

```
>>> result = shgo(eggholder, bounds, n=64, sampling_method='sobol')
>>> result.x, result.fun
(array([512.        , 404.23180824]), -959.6406627208397)
```

shgo also has a return for any other local minima that was found, these can be called using:

```
>>> result.xl
array([[ 512.        ,  404.23180824],
       [ 283.0759062 , -487.12565635],
       [-294.66820039, -462.01964031],
       [-105.87688911,  423.15323845],
       [-242.97926   ,  274.38030925],
       [-506.25823477,    6.3131022 ],
       [-408.71980731, -156.10116949],
       [ 150.23207937,  301.31376595],
       [  91.00920901, -391.283763  ],
       [ 202.89662724, -269.38043241],
       [ 361.66623976, -106.96493868],
       [-219.40612786, -244.06020508]])
```

```
>>> result.funl
array([-959.64066272, -718.16745962, -704.80659592, -565.99778097,
       -559.78685655, -557.36868733, -507.87385942, -493.9605115 ,
       -426.48799655, -421.15571437, -419.31194957, -410.98477763])
```

These results are useful in applications where there are many global minima and the values of other global minima are desired or where the local minima can provide insight into the system (for example morphologies in physical chemistry [4]).

If we want to find a larger number of local minima, we can increase the number of sampling points or the number of iterations. We'll increase the number of sampling points to 64 and the number of iterations from the default of 1 to 3. Using `simplicial` this would have given us 64 x 3 = 192 initial sampling points.

```
>>> result_2 = shgo(eggholder, bounds, n=64, iters=3, sampling_method=
↪'sobol')
>>> len(result.xl), len(result_2.xl)
(12, 20)
```

Note the difference between, e.g., `n=192, iters=1` and `n=64, iters=3`. In the first case the promising points contained in the minimiser pool are processed only once. In the latter case it is processed every 64 sampling points for a total of 3 times.

To demonstrate solving problems with non-linear constraints consider the following example from Hock and Schittkowski problem 73 (cattle-feed) [3]:

```
minimize: f = 24.55 * x_1 + 26.75 * x_2 + 39 * x_3 + 40.50 * x_4

subject to: 2.3 * x_1 + 5.6 * x_2 + 11.1 * x_3 + 1.3 * x_4 - 5     >= 0,

            12 * x_1 + 11.9 * x_2 + 41.8 * x_3 + 52.1 * x_4 - 21
                -1.645 * sqrt(0.28 * x_1**2 + 0.19 * x_2**2 +
                              20.5 * x_3**2 + 0.62 * x_4**2)        >= 0,

            x_1 + x_2 + x_3 + x_4 - 1                               == 0,

            1 >= x_i >= 0 for all i
```

The approximate answer given in [3] is:

```
f([0.6355216, -0.12e-11, 0.3127019, 0.05177655]) = 29.894378
```

```
>>> def f(x):  # (cattle-feed)
...     return 24.55*x[0] + 26.75*x[1] + 39*x[2] + 40.50*x[3]
...
>>> def g1(x):
...     return 2.3*x[0] + 5.6*x[1] + 11.1*x[2] + 1.3*x[3] - 5  # >=0
...
>>> def g2(x):
...     return (12*x[0] + 11.9*x[1] +41.8*x[2] + 52.1*x[3] - 21
...             - 1.645 * np.sqrt(0.28*x[0]**2 + 0.19*x[1]**2
...                               + 20.5*x[2]**2 + 0.62*x[3]**2)
...             ) # >=0
...
>>> def h1(x):
...     return x[0] + x[1] + x[2] + x[3] - 1  # == 0
...
>>> cons = ({'type': 'ineq', 'fun': g1},
...         {'type': 'ineq', 'fun': g2},
...         {'type': 'eq', 'fun': h1})
>>> bounds = [(0, 1.0),]*4
>>> res = shgo(f, bounds, iters=3, constraints=cons)
>>> res
     fun: 29.894378159142136
    funl: array([29.89437816])
 message: 'Optimization terminated successfully.'
    nfev: 114
```

scipy.optimize.dual_annealing

scipy.optimize.**dual_annealing**(*func*, *bounds*, *args=()*, *maxiter=1000*, *local_search_options={}*, *initial_temp=5230.0*, *restart_temp_ratio=2e-05*, *visit=2.62*, *accept=-5.0*, *maxfun=10000000.0*, *seed=None*, *no_local_search=False*, *callback=None*, *x0=None*)

Find the global minimum of a function using Dual Annealing.

Parameters

func [callable] The objective function to be minimized. Must be in the form `f(x, *args)`, where `x` is the argument in the form of a 1-D array and `args` is a tuple of any additional fixed parameters needed to completely specify the function.

bounds [sequence, shape (n, 2)] Bounds for variables. `(min, max)` pairs for each element in `x`, defining bounds for the objective function parameter.

args [tuple, optional] Any additional fixed parameters needed to completely specify the objective function.

maxiter [int, optional] The maximum number of global search iterations. Default value is 1000.

local_search_options
[dict, optional] Extra keyword arguments to be passed to the local minimizer (*minimize*). Some important options could be: `method` for the minimizer method to use and `args` for objective function additional arguments.

initial_temp
[float, optional] The initial temperature, use higher values to facilitates a wider search of the energy landscape, allowing dual_annealing to escape local minima that it is trapped in. Default value is 5230. Range is (0.01, 5.e4].

restart_temp_ratio
[float, optional] During the annealing process, temperature is decreasing, when it reaches `initial_temp * restart_temp_ratio`, the reannealing process is triggered. Default value of the ratio is 2e-5. Range is (0, 1).

visit [float, optional] Parameter for visiting distribution. Default value is 2.62. Higher values give the visiting distribution a heavier tail, this makes the algorithm jump to a more distant region. The value range is (1, 3].

accept [float, optional] Parameter for acceptance distribution. It is used to control the probability of acceptance. The lower the acceptance parameter, the smaller the probability of acceptance. Default value is -5.0 with a range (-1e4, -5].

maxfun [int, optional] Soft limit for the number of objective function calls. If the algorithm is in the middle of a local search, this number will be exceeded, the algorithm will stop just after the local search is done. Default value is 1e7.

seed [{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional
If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used. Specify *seed* for repeatable minimizations. The random numbers generated with this seed only affect the visiting distribution function and new coordinates generation.

no_local_search
[bool, optional] If *no_local_search* is set to True, a traditional Generalized Simulated Annealing will be performed with no local search strategy applied.

callback [callable, optional] A callback function with signature `callback(x, f, context)`, which will be called for all minima found. `x` and `f` are the coordinates and function value of the latest minimum found, and `context` has value in [0, 1, 2], with the following meaning:
- 0: minimum detected in the annealing process.
- 1: detection occurred in the local search process.
- 2: detection done in the dual annealing process.

If the callback implementation returns True, the algorithm will stop.

x0 [ndarray, shape(n,), optional] Coordinates of a single N-D starting point.

Returns

res [OptimizeResult] The optimization result represented as a *`OptimizeResult`* object. Important attributes are: `x` the solution array, `fun` the value of the function at the solution, and `message` which describes the cause of the termination. See *`OptimizeResult`* for a description of other attributes.

Notes

This function implements the Dual Annealing optimization. This stochastic approach derived from [3] combines the generalization of CSA (Classical Simulated Annealing) and FSA (Fast Simulated Annealing) [1] [2] coupled to a strategy for applying a local search on accepted locations [4]. An alternative implementation of this same algorithm is described in [5] and benchmarks are presented in [6]. This approach introduces an advanced method to refine the solution found by the generalized annealing process. This algorithm uses a distorted Cauchy-Lorentz visiting distribution, with its shape controlled by the parameter q_v

$$g_{q_v}(\Delta x(t)) \propto \frac{[T_{q_v}(t)]^{-\frac{D}{3-q_v}}}{\left[1+(q_v-1)\frac{(\Delta x(t))^2}{[T_{q_v}(t)]^{\frac{2}{3-q_v}}}\right]^{\frac{1}{q_v-1}+\frac{D-1}{2}}}$$

Where t is the artificial time. This visiting distribution is used to generate a trial jump distance $\Delta x(t)$ of variable $x(t)$ under artificial temperature $T_{q_v}(t)$.

From the starting point, after calling the visiting distribution function, the acceptance probability is computed as follows:

$$p_{q_a} = \min\left\{1, \left[1-(1-q_a)\beta\Delta E\right]^{\frac{1}{1-q_a}}\right\}$$

Where q_a is a acceptance parameter. For $q_a < 1$, zero acceptance probability is assigned to the cases where

$$[1-(1-q_a)\beta\Delta E] < 0$$

The artificial temperature $T_{q_v}(t)$ is decreased according to

$$T_{q_v}(t) = T_{q_v}(1)\frac{2^{q_v-1}-1}{(1+t)^{q_v-1}-1}$$

Where q_v is the visiting parameter.

New in version 1.2.0.

Examples

The following example is a 10-D problem, with many local minima. The function involved is called Rastrigin (https://en.wikipedia.org/wiki/Rastrigin_function)

```
>>> from scipy.optimize import dual_annealing
>>> func = lambda x: np.sum(x*x - 10*np.cos(2*np.pi*x)) + 10*np.size(x)
>>> lw = [-5.12] * 10
>>> up = [5.12] * 10
>>> ret = dual_annealing(func, bounds=list(zip(lw, up)))
>>> ret.x
array([-4.26437714e-09, -3.91699361e-09, -1.86149218e-09, -3.97165720e-09,
       -6.29151648e-09, -6.53145322e-09, -3.93616815e-09, -6.55623025e-09,
       -6.05775280e-09, -5.00668935e-09]) # random
>>> ret.fun
0.000000
```

Least-squares and curve fitting

Nonlinear least-squares

least_squares(fun, x0[, jac, bounds, …])	Solve a nonlinear least-squares problem with bounds on the variables.

scipy.optimize.least_squares

scipy.optimize.**least_squares**(*fun*, *x0*, *jac='2-point'*, *bounds=(- inf, inf)*, *method='trf'*, *ftol=1e-08*, *xtol=1e-08*, *gtol=1e-08*, *x_scale=1.0*, *loss='linear'*, *f_scale=1.0*, *diff_step=None*, *tr_solver=None*, *tr_options={}*, *jac_sparsity=None*, *max_nfev=None*, *verbose=0*, *args=()*, *kwargs={}*)

Solve a nonlinear least-squares problem with bounds on the variables.

Given the residuals f(x) (an m-D real function of n real variables) and the loss function rho(s) (a scalar function), *least_squares* finds a local minimum of the cost function F(x):

```
minimize F(x) = 0.5 * sum(rho(f_i(x)**2), i = 0, ..., m - 1)
subject to lb <= x <= ub
```

The purpose of the loss function rho(s) is to reduce the influence of outliers on the solution.

Parameters

fun [callable] Function which computes the vector of residuals, with the signature `fun(x, *args, **kwargs)`, i.e., the minimization proceeds with respect to its first argument.

The argument `x` passed to this function is an ndarray of shape (n,) (never a scalar, even for n=1). It must allocate and return a 1-D array_like of shape (m,) or a scalar. If the argument `x` is complex or the function `fun` returns complex residuals, it must be wrapped in a real function of real arguments, as shown at the end of the Examples section.

x0 [array_like with shape (n,) or float] Initial guess on independent variables. If float, it will be treated as a 1-D array with one element.

jac [{'2-point', '3-point', 'cs', callable}, optional] Method of computing the Jacobian matrix (an m-by-n matrix, where element (i, j) is the partial derivative of f[i] with respect to x[j]). The keywords select a finite difference scheme for numerical estimation. The scheme '3-point' is more accurate, but requires twice as many operations as '2-point' (default). The scheme 'cs' uses complex steps, and while potentially the most accurate, it is applicable only when *fun* correctly handles complex inputs and can be analytically continued to the complex plane. Method 'lm' always uses the '2-point' scheme. If callable, it is used as `jac(x, *args, **kwargs)` and should return a good approximation (or the exact value) for the Jacobian as an array_like (np.atleast_2d is applied), a sparse matrix (csr_matrix preferred for performance) or a *scipy.sparse.linalg.LinearOperator*.

bounds [2-tuple of array_like, optional] Lower and upper bounds on independent variables. Defaults to no bounds. Each array must match the size of *x0* or be a scalar, in the latter case a bound will be the same for all variables. Use `np.inf` with an appropriate sign to disable bounds on all or some variables.

method [{'trf', 'dogbox', 'lm'}, optional] Algorithm to perform minimization.

- 'trf' : Trust Region Reflective algorithm, particularly suitable for large sparse problems with bounds. Generally robust method.
- 'dogbox' : dogleg algorithm with rectangular trust regions, typical use case is small problems with bounds. Not recommended for problems with rank-deficient Jacobian.
- 'lm' : Levenberg-Marquardt algorithm as implemented in MINPACK. Doesn't handle bounds and sparse Jacobians. Usually the most efficient method for small unconstrained problems.

Default is 'trf'. See Notes for more information.

ftol [float or None, optional] Tolerance for termination by the change of the cost function. Default is 1e-8. The optimization process is stopped when `dF < ftol * F`, and there was an adequate agreement between a local quadratic model and the true model in the last step.
If None and 'method' is not 'lm', the termination by this condition is disabled. If 'method' is 'lm', this tolerance must be higher than machine epsilon.

xtol [float or None, optional] Tolerance for termination by the change of the independent variables. Default is 1e-8. The exact condition depends on the *method* used:

- For 'trf' and 'dogbox' : `norm(dx) < xtol * (xtol + norm(x))`.
- For 'lm' : `Delta < xtol * norm(xs)`, where `Delta` is a trust-region radius and `xs` is the value of `x` scaled according to *x_scale* parameter (see below).

If None and 'method' is not 'lm', the termination by this condition is disabled. If 'method' is 'lm', this tolerance must be higher than machine epsilon.

gtol [float or None, optional] Tolerance for termination by the norm of the gradient. Default is 1e-8. The exact condition depends on a *method* used:

- For 'trf' : `norm(g_scaled, ord=np.inf) < gtol`, where `g_scaled` is the value of the gradient scaled to account for the presence of the bounds [STIR].
- For 'dogbox' : `norm(g_free, ord=np.inf) < gtol`, where `g_free` is the gradient with respect to the variables which are not in the optimal state on the boundary.
- For 'lm' : the maximum absolute value of the cosine of angles between columns of the Jacobian and the residual vector is less than *gtol*, or the residual vector is zero.

If None and 'method' is not 'lm', the termination by this condition is disabled. If 'method' is 'lm', this tolerance must be higher than machine epsilon.

x_scale [array_like or 'jac', optional] Characteristic scale of each variable. Setting *x_scale* is equivalent to reformulating the problem in scaled variables `xs = x / x_scale`. An alternative view is that the size of a trust region along jth dimension is proportional to `x_scale[j]`.

Improved convergence may be achieved by setting *x_scale* such that a step of a given size along any of the scaled variables has a similar effect on the cost function. If set to 'jac', the scale is iteratively updated using the inverse norms of the columns of the Jacobian matrix (as described in [JJMore]).

loss [str or callable, optional] Determines the loss function. The following keyword values are allowed:

- 'linear' (default) : `rho(z) = z`. Gives a standard least-squares problem.
- 'soft_l1' : `rho(z) = 2 * ((1 + z)**0.5 - 1)`. The smooth approximation of l1 (absolute value) loss. Usually a good choice for robust least squares.
- 'huber' : `rho(z) = z if z <= 1 else 2*z**0.5 - 1`. Works similarly to 'soft_l1'.
- 'cauchy' : `rho(z) = ln(1 + z)`. Severely weakens outliers influence, but may cause difficulties in optimization process.
- 'arctan' : `rho(z) = arctan(z)`. Limits a maximum loss on a single residual, has properties similar to 'cauchy'.

If callable, it must take a 1-D ndarray `z=f**2` and return an array_like with shape (3, m) where row 0 contains function values, row 1 contains first derivatives and row 2 contains second derivatives. Method 'lm' supports only 'linear' loss.

f_scale [float, optional] Value of soft margin between inlier and outlier residuals, default is 1.0. The loss function is evaluated as follows `rho_(f**2) = C**2 * rho(f**2 / C**2)`, where `C` is *f_scale*, and `rho` is determined by *loss* parameter. This parameter has no effect with `loss='linear'`, but for other *loss* values it is of crucial importance.

max_nfev [None or int, optional] Maximum number of function evaluations before the termination. If None (default), the value is chosen automatically:

- For 'trf' and 'dogbox' : 100 * n.
- For 'lm' : 100 * n if *jac* is callable and 100 * n * (n + 1) otherwise (because 'lm' counts function calls in Jacobian estimation).

diff_step [None or array_like, optional] Determines the relative step size for the finite difference approximation of the Jacobian. The actual step is computed as `x * diff_step`. If None (default), then *diff_step* is taken to be a conventional "optimal" power of machine epsilon for the finite difference scheme used [NR].

tr_solver [{None, 'exact', 'lsmr'}, optional] Method for solving trust-region subproblems, relevant only for 'trf' and 'dogbox' methods.

- 'exact' is suitable for not very large problems with dense Jacobian matrices. The computational complexity per iteration is comparable to a singular value decomposition of the Jacobian matrix.
- 'lsmr' is suitable for problems with sparse and large Jacobian matrices. It uses the iterative procedure *scipy.sparse.linalg.lsmr* for finding a solution of a linear least-squares problem and only requires matrix-vector product evaluations.

If None (default), the solver is chosen based on the type of Jacobian returned on the first iteration.

tr_options [dict, optional] Keyword options passed to trust-region solver.

- `tr_solver='exact'`: *tr_options* are ignored.
- `tr_solver='lsmr'`: options for *scipy.sparse.linalg.lsmr*. Additionally, `method='trf'` supports 'regularize' option (bool, default is True), which adds a regularization term to the normal equation, which improves convergence if the Jacobian is rank-deficient [Byrd] (eq. 3.4).

jac_sparsity [{None, array_like, sparse matrix}, optional] Defines the sparsity structure of the Jacobian matrix for finite difference estimation, its shape must be (m, n). If the Jacobian has only few non-zero elements in *each* row, providing the sparsity structure will greatly speed up the computations [Curtis]. A zero entry means that a corresponding element in the Jacobian is identically zero. If provided, forces the use of 'lsmr' trust-region solver. If None (default), then dense differencing will be used. Has no effect for 'lm' method.

verbose [{0, 1, 2}, optional] Level of algorithm's verbosity:
- 0 (default) : work silently.
- 1 : display a termination report.
- 2 : display progress during iterations (not supported by 'lm' method).

args, kwargs
[tuple and dict, optional] Additional arguments passed to *fun* and *jac*. Both empty by default. The calling signature is `fun(x, *args, **kwargs)` and the same for *jac*.

Returns

result [OptimizeResult] `OptimizeResult` with the following fields defined:

x [ndarray, shape (n,)] Solution found.

cost [float] Value of the cost function at the solution.

fun [ndarray, shape (m,)] Vector of residuals at the solution.

jac [ndarray, sparse matrix or LinearOperator, shape (m, n)] Modified Jacobian matrix at the solution, in the sense that J^T J is a Gauss-Newton approximation of the Hessian of the cost function. The type is the same as the one used by the algorithm.

grad [ndarray, shape (m,)] Gradient of the cost function at the solution.

optimality [float] First-order optimality measure. In unconstrained problems, it is always the uniform norm of the gradient. In constrained problems, it is the quantity which was compared with *gtol* during iterations.

active_mask
[ndarray of int, shape (n,)] Each component shows whether a corresponding constraint is active (that is, whether a variable is at the bound):
- 0 : a constraint is not active.
- -1 : a lower bound is active.
- 1 : an upper bound is active.

Might be somewhat arbitrary for 'trf' method as it generates a sequence of strictly feasible iterates and *active_mask* is determined within a tolerance threshold.

nfev [int] Number of function evaluations done. Methods 'trf' and 'dogbox' do not count function calls for numerical Jacobian approximation, as opposed to 'lm' method.

njev [int or None] Number of Jacobian evaluations done. If numerical Jacobian approximation is used in 'lm' method, it is set to None.

status [int] The reason for algorithm termination:
- -1 : improper input parameters status returned from MINPACK.
- 0 : the maximum number of function evaluations is exceeded.
- 1 : *gtol* termination condition is satisfied.
- 2 : *ftol* termination condition is satisfied.
- 3 : *xtol* termination condition is satisfied.
- 4 : Both *ftol* and *xtol* termination conditions are satisfied.

message [str] Verbal description of the termination reason.

success [bool] True if one of the convergence criteria is satisfied (*status* > 0).

`leastsq`

A legacy wrapper for the MINPACK implementation of the Levenberg-Marquadt algorithm.

`curve_fit`

Least-squares minimization applied to a curve-fitting problem.

Notes

Method 'lm' (Levenberg-Marquardt) calls a wrapper over least-squares algorithms implemented in MINPACK (lmder, lmdif). It runs the Levenberg-Marquardt algorithm formulated as a trust-region type algorithm. The implementation is based on paper [JJMore], it is very robust and efficient with a lot of smart tricks. It should be your first choice for unconstrained problems. Note that it doesn't support bounds. Also, it doesn't work when m < n.

Method 'trf' (Trust Region Reflective) is motivated by the process of solving a system of equations, which constitute the first-order optimality condition for a bound-constrained minimization problem as formulated in [STIR]. The algorithm iteratively solves trust-region subproblems augmented by a special diagonal quadratic term and with trust-region shape determined by the distance from the bounds and the direction of the gradient. This enhancements help to avoid making steps directly into bounds and efficiently explore the whole space of variables. To further improve convergence, the algorithm considers search directions reflected from the bounds. To obey theoretical requirements, the algorithm keeps iterates strictly feasible. With dense Jacobians trust-region subproblems are solved by an exact method very similar to the one described in [JJMore] (and implemented in MINPACK). The difference from the MINPACK implementation is that a singular value decomposition of a Jacobian matrix is done once per iteration, instead of a QR decomposition and series of Givens rotation eliminations. For large sparse Jacobians a 2-D subspace approach of solving trust-region subproblems is used [STIR], [Byrd]. The subspace is spanned by a scaled gradient and an approximate Gauss-Newton solution delivered by *scipy.sparse.linalg.lsmr*. When no constraints are imposed the algorithm is very similar to MINPACK and has generally comparable performance. The algorithm works quite robust in unbounded and bounded problems, thus it is chosen as a default algorithm.

Method 'dogbox' operates in a trust-region framework, but considers rectangular trust regions as opposed to conventional ellipsoids [Voglis]. The intersection of a current trust region and initial bounds is again rectangular, so on each iteration a quadratic minimization problem subject to bound constraints is solved approximately by Powell's dogleg method [NumOpt]. The required Gauss-Newton step can be computed exactly for dense Jacobians or approximately by *scipy.sparse.linalg.lsmr* for large sparse Jacobians. The algorithm is likely to exhibit slow convergence when the rank of Jacobian is less than the number of variables. The algorithm often outperforms 'trf' in bounded problems with a small number of variables.

Robust loss functions are implemented as described in [BA]. The idea is to modify a residual vector and a Jacobian matrix on each iteration such that computed gradient and Gauss-Newton Hessian approximation match the true gradient and Hessian approximation of the cost function. Then the algorithm proceeds in a normal way, i.e., robust loss functions are implemented as a simple wrapper over standard least-squares algorithms.

New in version 0.17.0.

Examples

In this example we find a minimum of the Rosenbrock function without bounds on independent variables.

```
>>> def fun_rosenbrock(x):
...     return np.array([10 * (x[1] - x[0]**2), (1 - x[0])])
```

Notice that we only provide the vector of the residuals. The algorithm constructs the cost function as a sum of squares of the residuals, which gives the Rosenbrock function. The exact minimum is at `x = [1.0, 1.0]`.

```
>>> from scipy.optimize import least_squares
>>> x0_rosenbrock = np.array([2, 2])
>>> res_1 = least_squares(fun_rosenbrock, x0_rosenbrock)
```

(continues on next page)

(continued from previous page)

```
>>> res_1.x
array([ 1.,  1.])
>>> res_1.cost
9.8669242910846867e-30
>>> res_1.optimality
8.8928864934219529e-14
```

We now constrain the variables, in such a way that the previous solution becomes infeasible. Specifically, we require that `x[1] >= 1.5`, and `x[0]` left unconstrained. To this end, we specify the *bounds* parameter to *`least_squares`* in the form `bounds=([-np.inf, 1.5], np.inf)`.

We also provide the analytic Jacobian:

```
>>> def jac_rosenbrock(x):
...     return np.array([
...         [-20 * x[0], 10],
...         [-1, 0]])
```

Putting this all together, we see that the new solution lies on the bound:

```
>>> res_2 = least_squares(fun_rosenbrock, x0_rosenbrock, jac_rosenbrock,
...                       bounds=([-np.inf, 1.5], np.inf))
>>> res_2.x
array([ 1.22437075,  1.5       ])
>>> res_2.cost
0.025213093946805685
>>> res_2.optimality
1.5885401433157753e-07
```

Now we solve a system of equations (i.e., the cost function should be zero at a minimum) for a Broyden tridiagonal vector-valued function of 100000 variables:

```
>>> def fun_broyden(x):
...     f = (3 - x) * x + 1
...     f[1:] -= x[:-1]
...     f[:-1] -= 2 * x[1:]
...     return f
```

The corresponding Jacobian matrix is sparse. We tell the algorithm to estimate it by finite differences and provide the sparsity structure of Jacobian to significantly speed up this process.

```
>>> from scipy.sparse import lil_matrix
>>> def sparsity_broyden(n):
...     sparsity = lil_matrix((n, n), dtype=int)
...     i = np.arange(n)
...     sparsity[i, i] = 1
...     i = np.arange(1, n)
...     sparsity[i, i - 1] = 1
...     i = np.arange(n - 1)
...     sparsity[i, i + 1] = 1
...     return sparsity
...
>>> n = 100000
```

(continues on next page)

(continued from previous page)

```
>>> x0_broyden = -np.ones(n)
...
>>> res_3 = least_squares(fun_broyden, x0_broyden,
...                       jac_sparsity=sparsity_broyden(n))
>>> res_3.cost
4.5687069299604613e-23
>>> res_3.optimality
1.1650454296851518e-11
```

Let's also solve a curve fitting problem using robust loss function to take care of outliers in the data. Define the model function as `y = a + b * exp(c * t)`, where t is a predictor variable, y is an observation and a, b, c are parameters to estimate.

First, define the function which generates the data with noise and outliers, define the model parameters, and generate data:

```
>>> from numpy.random import default_rng
>>> rng = default_rng()
>>> def gen_data(t, a, b, c, noise=0., n_outliers=0, seed=None):
...     rng = default_rng(seed)
...
...     y = a + b * np.exp(t * c)
...
...     error = noise * rng.standard_normal(t.size)
...     outliers = rng.integers(0, t.size, n_outliers)
...     error[outliers] *= 10
...
...     return y + error
...
>>> a = 0.5
>>> b = 2.0
>>> c = -1
>>> t_min = 0
>>> t_max = 10
>>> n_points = 15
...
>>> t_train = np.linspace(t_min, t_max, n_points)
>>> y_train = gen_data(t_train, a, b, c, noise=0.1, n_outliers=3)
```

Define function for computing residuals and initial estimate of parameters.

```
>>> def fun(x, t, y):
...     return x[0] + x[1] * np.exp(x[2] * t) - y
...
>>> x0 = np.array([1.0, 1.0, 0.0])
```

Compute a standard least-squares solution:

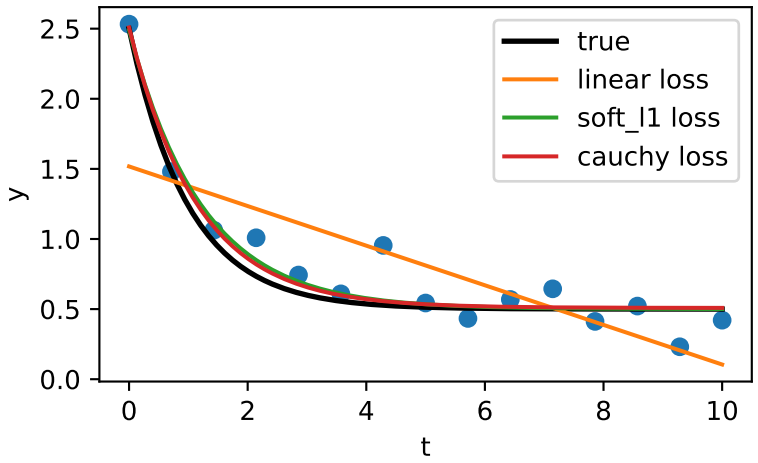
```
>>> res_lsq = least_squares(fun, x0, args=(t_train, y_train))
```

Now compute two solutions with two different robust loss functions. The parameter *f_scale* is set to 0.1, meaning that inlier residuals should not significantly exceed 0.1 (the noise level used).

```
>>> res_soft_l1 = least_squares(fun, x0, loss='soft_l1', f_scale=0.1,
...                             args=(t_train, y_train))
>>> res_log = least_squares(fun, x0, loss='cauchy', f_scale=0.1,
...                         args=(t_train, y_train))
```

And, finally, plot all the curves. We see that by selecting an appropriate *loss* we can get estimates close to optimal even in the presence of strong outliers. But keep in mind that generally it is recommended to try 'soft_l1' or 'huber' losses first (if at all necessary) as the other two options may cause difficulties in optimization process.

```
>>> t_test = np.linspace(t_min, t_max, n_points * 10)
>>> y_true = gen_data(t_test, a, b, c)
>>> y_lsq = gen_data(t_test, *res_lsq.x)
>>> y_soft_l1 = gen_data(t_test, *res_soft_l1.x)
>>> y_log = gen_data(t_test, *res_log.x)
...
>>> import matplotlib.pyplot as plt
>>> plt.plot(t_train, y_train, 'o')
>>> plt.plot(t_test, y_true, 'k', linewidth=2, label='true')
>>> plt.plot(t_test, y_lsq, label='linear loss')
>>> plt.plot(t_test, y_soft_l1, label='soft_l1 loss')
>>> plt.plot(t_test, y_log, label='cauchy loss')
>>> plt.xlabel("t")
>>> plt.ylabel("y")
>>> plt.legend()
>>> plt.show()
```



In the next example, we show how complex-valued residual functions of complex variables can be optimized with `least_squares()`. Consider the following function:

```
>>> def f(z):
...     return z - (0.5 + 0.5j)
```

We wrap it into a function of real variables that returns real residuals by simply handling the real and imaginary parts as independent variables:

```
>>> def f_wrap(x):
...     fx = f(x[0] + 1j*x[1])
...     return np.array([fx.real, fx.imag])
```

Thus, instead of the original m-D complex function of n complex variables we optimize a 2m-D real function of 2n real variables:

```
>>> from scipy.optimize import least_squares
>>> res_wrapped = least_squares(f_wrap, (0.1, 0.1), bounds=([0, 0], [1,␣
↪1]))
>>> z = res_wrapped.x[0] + res_wrapped.x[1]*1j
>>> z
(0.49999999999925893+0.49999999999925893j)
```

Linear least-squares

nnls(A, b[, maxiter])	Solve `argmin_x || Ax - b ||_2` for `x>=0`.
lsq_linear(A, b[, bounds, method, tol, …])	Solve a linear least-squares problem with bounds on the variables.

scipy.optimize.nnls

scipy.optimize.**nnls**(*A*, *b*, *maxiter=None*)

Solve `argmin_x || Ax - b ||_2` for `x>=0`. This is a wrapper for a FORTRAN non-negative least squares solver.

Parameters

A [ndarray] Matrix `A` as shown above.

b [ndarray] Right-hand side vector.

maxiter: int, optional

Maximum number of iterations, optional. Default is `3 * A.shape[1]`.

Returns

x [ndarray] Solution vector.

rnorm [float] The residual, `|| Ax-b ||_2`.

See also:

lsq_linear

Linear least squares with bounds on the variables

Notes

The FORTRAN code was published in the book below. The algorithm is an active set method. It solves the KKT (Karush-Kuhn-Tucker) conditions for the non-negative least squares problem.

Examples

```
>>> from scipy.optimize import nnls
...
>>> A = np.array([[1, 0], [1, 0], [0, 1]])
>>> b = np.array([2, 1, 1])
>>> nnls(A, b)
(array([1.5, 1. ]), 0.7071067811865475)
```

```
>>> b = np.array([-1, -1, -1])
>>> nnls(A, b)
(array([0., 0.]), 1.7320508075688772)
```

scipy.optimize.lsq_linear

scipy.optimize.**lsq_linear**(*A*, *b*, *bounds=(- inf, inf)*, *method='trf'*, *tol=1e-10*, *lsq_solver=None*, *lsmr_tol=None*, *max_iter=None*, *verbose=0*)

Solve a linear least-squares problem with bounds on the variables.

Given a m-by-n design matrix A and a target vector b with m elements, *lsq_linear* solves the following optimization problem:

```
minimize 0.5 * ||A x - b||**2
subject to lb <= x <= ub
```

This optimization problem is convex, hence a found minimum (if iterations have converged) is guaranteed to be global.

Parameters

A [array_like, sparse matrix of LinearOperator, shape (m, n)] Design matrix. Can be *scipy.sparse.linalg.LinearOperator*.

b [array_like, shape (m,)] Target vector.

bounds [2-tuple of array_like, optional] Lower and upper bounds on independent variables. Defaults to no bounds. Each array must have shape (n,) or be a scalar, in the latter case a bound will be the same for all variables. Use `np.inf` with an appropriate sign to disable bounds on all or some variables.

method ['trf' or 'bvls', optional] Method to perform minimization.

- 'trf' : Trust Region Reflective algorithm adapted for a linear least-squares problem. This is an interior-point-like method and the required number of iterations is weakly correlated with the number of variables.

- 'bvls' : Bounded-variable least-squares algorithm. This is an active set method, which requires the number of iterations comparable to the number of variables. Can't be used when *A* is sparse or LinearOperator.

Default is 'trf'.

tol [float, optional] Tolerance parameter. The algorithm terminates if a relative change of the cost function is less than *tol* on the last iteration. Additionally, the first-order optimality measure is considered:

- `method='trf'` terminates if the uniform norm of the gradient, scaled to account for the presence of the bounds, is less than *tol*.
- `method='bvls'` terminates if Karush-Kuhn-Tucker conditions are satisfied within *tol* tolerance.

lsq_solver [{None, 'exact', 'lsmr'}, optional] Method of solving unbounded least-squares problems throughout iterations:

- 'exact' : Use dense QR or SVD decomposition approach. Can't be used when *A* is sparse or LinearOperator.
- 'lsmr' : Use *scipy.sparse.linalg.lsmr* iterative procedure which requires only matrix-vector product evaluations. Can't be used with `method='bvls'`.

If None (default), the solver is chosen based on type of *A*.

lsmr_tol [None, float or 'auto', optional] Tolerance parameters 'atol' and 'btol' for *scipy.sparse.linalg.lsmr* If None (default), it is set to `1e-2 * tol`. If 'auto', the tolerance will be adjusted based on the optimality of the current iterate, which can speed up the optimization process, but is not always reliable.

max_iter [None or int, optional] Maximum number of iterations before termination. If None (default), it is set to 100 for `method='trf'` or to the number of variables for `method='bvls'` (not counting iterations for 'bvls' initialization).

verbose [{0, 1, 2}, optional] Level of algorithm's verbosity:

- 0 : work silently (default).
- 1 : display a termination report.
- 2 : display progress during iterations.

Returns

OptimizeResult with the following fields defined:

x [ndarray, shape (n,)] Solution found.

cost [float] Value of the cost function at the solution.

fun [ndarray, shape (m,)] Vector of residuals at the solution.

optimality [float] First-order optimality measure. The exact meaning depends on *method*, refer to the description of *tol* parameter.

active_mask

[ndarray of int, shape (n,)] Each component shows whether a corresponding constraint is active (that is, whether a variable is at the bound):

- 0 : a constraint is not active.
- -1 : a lower bound is active.
- 1 : an upper bound is active.

Might be somewhat arbitrary for the *trf* method as it generates a sequence of strictly feasible iterates and active_mask is determined within a tolerance threshold.

nit [int] Number of iterations. Zero if the unconstrained solution is optimal.

status [int] Reason for algorithm termination:

- -1 : the algorithm was not able to make progress on the last iteration.
- 0 : the maximum number of iterations is exceeded.
- 1 : the first-order optimality measure is less than *tol*.
- 2 : the relative change of the cost function is less than *tol*.
- 3 : the unconstrained solution is optimal.

message [str] Verbal description of the termination reason.

success [bool] True if one of the convergence criteria is satisfied (*status* > 0).

See also:

`nnls`

Linear least squares with non-negativity constraint.

`least_squares`

Nonlinear least squares with bounds on the variables.

Notes

The algorithm first computes the unconstrained least-squares solution by `numpy.linalg.lstsq` or *`scipy.sparse.linalg.lsmr`* depending on *lsq_solver*. This solution is returned as optimal if it lies within the bounds.

Method 'trf' runs the adaptation of the algorithm described in [STIR] for a linear least-squares problem. The iterations are essentially the same as in the nonlinear least-squares algorithm, but as the quadratic function model is always accurate, we don't need to track or modify the radius of a trust region. The line search (backtracking) is used as a safety net when a selected step does not decrease the cost function. Read more detailed description of the algorithm in *`scipy.optimize.least_squares`*.

Method 'bvls' runs a Python implementation of the algorithm described in [BVLS]. The algorithm maintains active and free sets of variables, on each iteration chooses a new variable to move from the active set to the free set and then solves the unconstrained least-squares problem on free variables. This algorithm is guaranteed to give an accurate solution eventually, but may require up to n iterations for a problem with n variables. Additionally, an ad-hoc initialization procedure is implemented, that determines which variables to set free or active initially. It takes some number of iterations before actual BVLS starts, but can significantly reduce the number of further iterations.

Examples

In this example, a problem with a large sparse matrix and bounds on the variables is solved.

```
>>> from scipy.sparse import rand
>>> from scipy.optimize import lsq_linear
>>> rng = np.random.default_rng()
...
>>> m = 20000
>>> n = 10000
...
>>> A = rand(m, n, density=1e-4, random_state=rng)
>>> b = rng.standard_normal(m)
...
>>> lb = rng.standard_normal(n)
>>> ub = lb + 1
...
>>> res = lsq_linear(A, b, bounds=(lb, ub), lsmr_tol='auto', verbose=1)
# may vary
The relative change of the cost function is less than `tol`.
```

Curve fitting

curve_fit(f, xdata, ydata[, p0, sigma, …])	Use non-linear least squares to fit a function, f, to data.

scipy.optimize.curve_fit

scipy.optimize.**curve_fit**(*f*, *xdata*, *ydata*, *p0=None*, *sigma=None*, *absolute_sigma=False*, *check_finite=True*, *bounds=(- inf, inf)*, *method=None*, *jac=None*, ***kwargs*)

Use non-linear least squares to fit a function, f, to data.

Assumes `ydata = f(xdata, *params) + eps`.

Parameters

f [callable] The model function, f(x, …). It must take the independent variable as the first argument and the parameters to fit as separate remaining arguments.

xdata [array_like or object] The independent variable where the data is measured. Should usually be an M-length sequence or an (k,M)-shaped array for functions with k predictors, but can actually be any object.

ydata [array_like] The dependent data, a length M array - nominally `f(xdata, ...)`.

p0 [array_like, optional] Initial guess for the parameters (length N). If None, then the initial values will all be 1 (if the number of parameters for the function can be determined using introspection, otherwise a ValueError is raised).

sigma [None or M-length sequence or MxM array, optional] Determines the uncertainty in *ydata*. If we define residuals as `r = ydata - f(xdata, *popt)`, then the interpretation of *sigma* depends on its number of dimensions:

- A 1-D *sigma* should contain values of standard deviations of errors in *ydata*. In this case, the optimized function is `chisq = sum((r / sigma) ** 2)`.
- A 2-D *sigma* should contain the covariance matrix of errors in *ydata*. In this case, the optimized function is `chisq = r.T @ inv(sigma) @ r`.
  New in version 0.19.

None (default) is equivalent of 1-D *sigma* filled with ones.

absolute_sigma [bool, optional] If True, *sigma* is used in an absolute sense and the estimated parameter covariance *pcov* reflects these absolute values.
If False (default), only the relative magnitudes of the *sigma* values matter. The returned parameter covariance matrix *pcov* is based on scaling *sigma* by a constant factor. This constant is set by demanding that the reduced *chisq* for the optimal parameters *popt* when using the *scaled sigma* equals unity. In other words, *sigma* is scaled to match the sample variance of the residuals after the fit. Default is False. Mathematically, `pcov(absolute_sigma=False) = pcov(absolute_sigma=True) * chisq(popt)/(M-N)`

check_finite [bool, optional] If True, check that the input arrays do not contain nans of infs, and raise a ValueError if they do. Setting this parameter to False may silently produce nonsensical results if the input arrays do contain nans. Default is True.

bounds [2-tuple of array_like, optional] Lower and upper bounds on parameters. Defaults to no bounds. Each element of the tuple must be either an array with the length equal to the

number of parameters, or a scalar (in which case the bound is taken to be the same for all parameters). Use `np.inf` with an appropriate sign to disable bounds on all or some parameters.
New in version 0.17.

method [{'lm', 'trf', 'dogbox'}, optional] Method to use for optimization. See *least_squares* for more details. Default is 'lm' for unconstrained problems and 'trf' if *bounds* are provided. The method 'lm' won't work when the number of observations is less than the number of variables, use 'trf' or 'dogbox' in this case.
New in version 0.17.

jac [callable, string or None, optional] Function with signature `jac(x, ...)` which computes the Jacobian matrix of the model function with respect to parameters as a dense array_like structure. It will be scaled according to provided *sigma*. If None (default), the Jacobian will be estimated numerically. String keywords for 'trf' and 'dogbox' methods can be used to select a finite difference scheme, see *least_squares*.
New in version 0.18.

kwargs Keyword arguments passed to *leastsq* for `method='lm'` or *least_squares* otherwise.

Returns

popt [array] Optimal values for the parameters so that the sum of the squared residuals of `f(xdata, *popt) - ydata` is minimized.

pcov [2-D array] The estimated covariance of popt. The diagonals provide the variance of the parameter estimate. To compute one standard deviation errors on the parameters use `perr = np.sqrt(np.diag(pcov))`.
How the *sigma* parameter affects the estimated covariance depends on *absolute_sigma* argument, as described above.
If the Jacobian matrix at the solution doesn't have a full rank, then 'lm' method returns a matrix filled with `np.inf`, on the other hand 'trf' and 'dogbox' methods use Moore-Penrose pseudoinverse to compute the covariance matrix.

Raises

ValueError
if either *ydata* or *xdata* contain NaNs, or if incompatible options are used.

RuntimeError
if the least-squares minimization fails.

OptimizeWarning
if covariance of the parameters can not be estimated.

See also:

least_squares

Minimize the sum of squares of nonlinear functions.

scipy.stats.linregress

Calculate a linear least squares regression for two sets of measurements.

Notes

With `method='lm'`, the algorithm uses the Levenberg-Marquardt algorithm through *leastsq*. Note that this algorithm can only deal with unconstrained problems.

Box constraints can be handled by methods 'trf' and 'dogbox'. Refer to the docstring of *least_squares* for more information.

Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.optimize import curve_fit
```

```
>>> def func(x, a, b, c):
...     return a * np.exp(-b * x) + c
```

Define the data to be fit with some noise:

```
>>> xdata = np.linspace(0, 4, 50)
>>> y = func(xdata, 2.5, 1.3, 0.5)
>>> rng = np.random.default_rng()
>>> y_noise = 0.2 * rng.normal(size=xdata.size)
>>> ydata = y + y_noise
>>> plt.plot(xdata, ydata, 'b-', label='data')
```

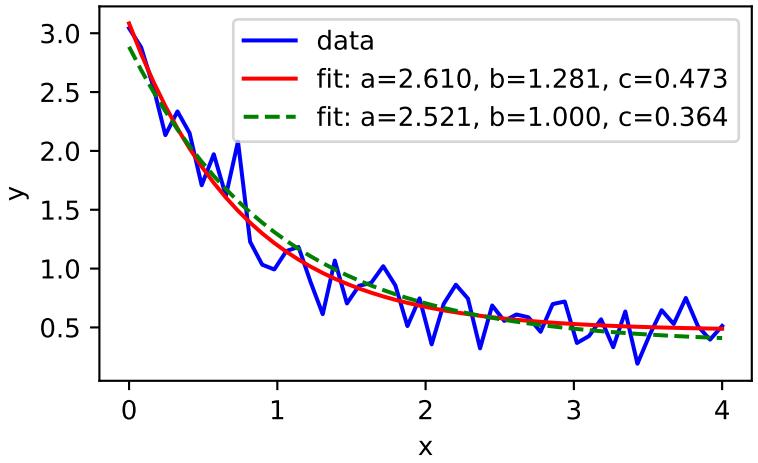
Fit for the parameters a, b, c of the function *func*:

```
>>> popt, pcov = curve_fit(func, xdata, ydata)
>>> popt
array([2.56274217, 1.37268521, 0.47427475])
>>> plt.plot(xdata, func(xdata, *popt), 'r-',
...          label='fit: a=%5.3f, b=%5.3f, c=%5.3f' % tuple(popt))
```

Constrain the optimization to the region of `0 <= a <= 3`, `0 <= b <= 1` and `0 <= c <= 0.5`:

```
>>> popt, pcov = curve_fit(func, xdata, ydata, bounds=(0, [3., 1., 0.5]))
>>> popt
array([2.43736712, 1.        , 0.34463856])
>>> plt.plot(xdata, func(xdata, *popt), 'g--',
...          label='fit: a=%5.3f, b=%5.3f, c=%5.3f' % tuple(popt))
```

```
>>> plt.xlabel('x')
>>> plt.ylabel('y')
>>> plt.legend()
>>> plt.show()
```



Root finding

Scalar functions

`root_scalar`(f[, args, method, bracket, …])	Find a root of a scalar function.
`brentq`(f, a, b[, args, xtol, rtol, maxiter, …])	Find a root of a function in a bracketing interval using Brent's method.
`brenth`(f, a, b[, args, xtol, rtol, maxiter, …])	Find a root of a function in a bracketing interval using Brent's method with hyperbolic extrapolation.
`ridder`(f, a, b[, args, xtol, rtol, maxiter, …])	Find a root of a function in an interval using Ridder's method.
`bisect`(f, a, b[, args, xtol, rtol, maxiter, …])	Find root of a function within an interval using bisection.
`newton`(func, x0[, fprime, args, tol, …])	Find a zero of a real or complex function using the Newton-Raphson (or secant or Halley's) method.
`toms748`(f, a, b[, args, k, xtol, rtol, …])	Find a zero using TOMS Algorithm 748 method.
`RootResults`(root, iterations, …)	Represents the root finding result.

scipy.optimize.root_scalar

scipy.optimize.**root_scalar**(*f*, *args=()*, *method=None*, *bracket=None*, *fprime=None*, *fprime2=None*, *x0=None*, *x1=None*, *xtol=None*, *rtol=None*, *maxiter=None*, *options=None*)

Find a root of a scalar function.

Parameters

f [callable] A function to find a root of.

args [tuple, optional] Extra arguments passed to the objective function and its derivative(s).

method [str, optional] Type of solver. Should be one of

- 'bisect' *(see here)*
- 'brentq' *(see here)*
- 'brenth' *(see here)*
- 'ridder' *(see here)*
- 'toms748' *(see here)*
- 'newton' *(see here)*
- 'secant' *(see here)*
- 'halley' *(see here)*

bracket: A sequence of 2 floats, optional

An interval bracketing a root. *f(x, *args)* must have different signs at the two endpoints.

x0 [float, optional] Initial guess.

sol [RootResults] The solution represented as a `RootResults` object. Important attributes are: `root` the solution , `converged` a boolean flag indicating if the algorithm exited successfully and `flag` which describes the cause of the termination. See *RootResults* for a description of other attributes.

See also:

show_options

Additional options accepted by the solvers

root

Find a root of a vector function.

Notes

This section describes the available solvers that can be selected by the 'method' parameter.

The default is to use the best method available for the situation presented. If a bracket is provided, it may use one of the bracketing methods. If a derivative and an initial value are specified, it may select one of the derivative-based methods. If no method is judged applicable, it will raise an Exception.

Examples

Find the root of a simple cubic

```
>>> from scipy import optimize
>>> def f(x):
...     return (x**3 - 1)  # only one real root at x = 1
```

```
>>> def fprime(x):
...     return 3*x**2
```

The *brentq* method takes as input a bracket

```
>>> sol = optimize.root_scalar(f, bracket=[0, 3], method='brentq')
>>> sol.root, sol.iterations, sol.function_calls
(1.0, 10, 11)
```

The *newton* method takes as input a single point and uses the derivative(s)

```
>>> sol = optimize.root_scalar(f, x0=0.2, fprime=fprime, method='newton')
>>> sol.root, sol.iterations, sol.function_calls
(1.0, 11, 22)
```

The function can provide the value and derivative(s) in a single call.

```
>>> def f_p_pp(x):
...     return (x**3 - 1), 3*x**2, 6*x
```

```
>>> sol = optimize.root_scalar(f_p_pp, x0=0.2, fprime=True, method='newton
↪')
>>> sol.root, sol.iterations, sol.function_calls
(1.0, 11, 11)
```

```
>>> sol = optimize.root_scalar(f_p_pp, x0=0.2, fprime=True, fprime2=True,␣
↪method='halley')
>>> sol.root, sol.iterations, sol.function_calls
(1.0, 7, 8)
```

scipy.optimize.brentq

scipy.optimize.**brentq**(*f*, *a*, *b*, *args=()*, *xtol=2e-12*, *rtol=8.881784197001252e-16*, *maxiter=100*, *full_output=False*, *disp=True*)

Find a root of a function in a bracketing interval using Brent's method.

Uses the classic Brent's method to find a zero of the function f on the sign changing interval [a , b]. Generally considered the best of the rootfinding routines here. It is a safe version of the secant method that uses inverse quadratic extrapolation. Brent's method combines root bracketing, interval bisection, and inverse quadratic interpolation. It is sometimes known as the van Wijngaarden-Dekker-Brent method. Brent (1973) claims convergence is guaranteed for functions computable within [a,b].

[Brent1973] provides the classic description of the algorithm. Another description can be found in a recent edition of Numerical Recipes, including [PressEtal1992]. A third description is at http://mathworld.wolfram.com/BrentsMethod.html. It should be easy to understand the algorithm just by reading our code. Our code diverges a bit from standard presentations: we choose a different formula for the extrapolation step.

Parameters

f [function] Python function returning a number. The function f must be continuous, and $f(a)$ and $f(b)$ must have opposite signs.

a [scalar] One end of the bracketing interval $[a, b]$.

b [scalar] The other end of the bracketing interval $[a, b]$.

xtol [number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter must be nonnegative. For nice functions, Brent's method will often satisfy the above condition with `xtol/2` and `rtol/2`. [Brent1973]

rtol [number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter cannot be smaller than its default value of `4*np.finfo(float).eps`. For nice functions, Brent's method will often satisfy the above condition with `xtol/2` and `rtol/2`. [Brent1973]

maxiter [int, optional] If convergence is not achieved in *maxiter* iterations, an error is raised. Must be >= 0.

args [tuple, optional] Containing extra arguments for the function f. f is called by `apply(f, (x)+args)`.

full_output

[bool, optional] If *full_output* is False, the root is returned. If *full_output* is True, the return value is `(x, r)`, where *x* is the root, and *r* is a *RootResults* object.

disp [bool, optional] If True, raise RuntimeError if the algorithm didn't converge. Otherwise, the convergence status is recorded in any *RootResults* return object.

Returns

x0 [float] Zero of f between *a* and *b*.

r [*RootResults* (present if `full_output = True`)] Object containing information about the convergence. In particular, `r.converged` is True if the routine converged.

Notes

f must be continuous. f(a) and f(b) must have opposite signs.

scipy.optimize.brenth

scipy.optimize.**brenth**(*f*, *a*, *b*, *args=()*, *xtol=2e-12*, *rtol=8.881784197001252e-16*, *maxiter=100*, *full_output=False*, *disp=True*)

Find a root of a function in a bracketing interval using Brent's method with hyperbolic extrapolation.

A variation on the classic Brent routine to find a zero of the function f between the arguments a and b that uses hyperbolic extrapolation instead of inverse quadratic extrapolation. There was a paper back in the 1980's ... f(a) and f(b) cannot have the same signs. Generally, on a par with the brent routine, but not as heavily tested. It is a safe version of the secant method that uses hyperbolic extrapolation. The version here is by Chuck Harris.

Parameters

f [function] Python function returning a number. f must be continuous, and f(a) and f(b) must have opposite signs.

a [scalar] One end of the bracketing interval [a,b].

b [scalar] The other end of the bracketing interval [a,b].

xtol [number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter must be nonnegative. As with *brentq*, for nice functions the method will often satisfy the above condition with `xtol/2` and `rtol/2`.

rtol [number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter cannot be smaller than its default value of `4*np.finfo(float).eps`. As with *brentq*, for nice functions the method will often satisfy the above condition with `xtol/2` and `rtol/2`.

maxiter [int, optional] If convergence is not achieved in *maxiter* iterations, an error is raised. Must be >= 0.

args [tuple, optional] Containing extra arguments for the function *f*. *f* is called by `apply(f, (x)+args)`.

full_output [bool, optional] If *full_output* is False, the root is returned. If *full_output* is True, the return value is `(x, r)`, where *x* is the root, and *r* is a *RootResults* object.

disp [bool, optional] If True, raise RuntimeError if the algorithm didn't converge. Otherwise, the convergence status is recorded in any *RootResults* return object.

Returns

x0 [float] Zero of *f* between *a* and *b*.

r [*RootResults* (present if `full_output = True`)] Object containing information about the convergence. In particular, `r.converged` is True if the routine converged.

Find a root of a function in an interval using Ridder's method.

Parameters

f	[function] Python function returning a number. f must be continuous, and f(a) and f(b) must have opposite signs.
a	[scalar] One end of the bracketing interval [a,b].
b	[scalar] The other end of the bracketing interval [a,b].
xtol	[number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter must be non-negative.
rtol	[number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter cannot be smaller than its default value of `4*np.finfo(float).eps`.
maxiter	[int, optional] If convergence is not achieved in *maxiter* iterations, an error is raised. Must be >= 0.
args	[tuple, optional] Containing extra arguments for the function *f*. *f* is called by `apply(f, (x)+args)`.

full_output
: [bool, optional] If *full_output* is False, the root is returned. If *full_output* is True, the return value is `(x, r)`, where *x* is the root, and *r* is a `RootResults` object.

disp
: [bool, optional] If True, raise RuntimeError if the algorithm didn't converge. Otherwise, the convergence status is recorded in any `RootResults` return object.

Returns

x0
: [float] Zero of *f* between *a* and *b*.

r
: [`RootResults` (present if `full_output = True`)] Object containing information about the convergence. In particular, `r.converged` is True if the routine converged.

1-D root-finding

fixed_point

scalar fixed-point finder

Notes

Uses [Ridders1979] method to find a zero of the function *f* between the arguments *a* and *b*. Ridders' method is faster than bisection, but not generally as fast as the Brent routines. [Ridders1979] provides the classic description and source of the algorithm. A description can also be found in any recent edition of Numerical Recipes.

The routine used here diverges slightly from standard presentations in order to be a bit more careful of tolerance.

Find root of a function within an interval using bisection.

Basic bisection routine to find a zero of the function *f* between the arguments *a* and *b*. *f(a)* and *f(b)* cannot have the same signs. Slow but sure.

Parameters

f [function] Python function returning a number. *f* must be continuous, and f(a) and f(b) must have opposite signs.

a [scalar] One end of the bracketing interval [a,b].

b [scalar] The other end of the bracketing interval [a,b].

xtol [number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter must be non-negative.

rtol [number, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter cannot be smaller than its default value of `4*np.finfo(float).eps`.

maxiter [int, optional] If convergence is not achieved in *maxiter* iterations, an error is raised. Must be >= 0.

args [tuple, optional] Containing extra arguments for the function *f*. *f* is called by `apply(f, (x)+args)`.

full_output

[bool, optional] If *full_output* is False, the root is returned. If *full_output* is True, the return value is `(x, r)`, where x is the root, and r is a *RootResults* object.

disp [bool, optional] If True, raise RuntimeError if the algorithm didn't converge. Otherwise, the convergence status is recorded in a *RootResults* return object.

Returns

x0 [float] Zero of *f* between *a* and *b*.

r [*RootResults* (present if `full_output = True`)] Object containing information about the convergence. In particular, `r.converged` is True if the routine converged.

scipy.optimize.newton

scipy.optimize.**newton**(*func*, *x0*, *fprime=None*, *args=()*, *tol=1.48e-08*, *maxiter=50*, *fprime2=None*, *x1=None*, *rtol=0.0*, *full_output=False*, *disp=True*)

Find a zero of a real or complex function using the Newton-Raphson (or secant or Halley's) method.

Find a zero of the function *func* given a nearby starting point *x0*. The Newton-Raphson method is used if the derivative *fprime* of *func* is provided, otherwise the secant method is used. If the second order derivative *fprime2* of *func* is also provided, then Halley's method is used.

If *x0* is a sequence with more than one item, then *newton* returns an array, and *func* must be vectorized and return a sequence or array of the same shape as its first argument. If *fprime* or *fprime2* is given, then its return must also have the same shape.

Parameters

func [callable] The function whose zero is wanted. It must be a function of a single variable of the form `f(x,a,b,c...)`, where `a,b,c...` are extra arguments that can be passed in the *args* parameter.

x0 [float, sequence, or ndarray] An initial estimate of the zero that should be somewhere near the actual zero. If not scalar, then *func* must be vectorized and return a sequence or array of the same shape as its first argument.

fprime [callable, optional] The derivative of the function when available and convenient. If it is None (default), then the secant method is used.

args [tuple, optional] Extra arguments to be used in the function call.

tol [float, optional] The allowable error of the zero value. If *func* is complex-valued, a larger *tol* is recommended as both the real and imaginary parts of *x* contribute to `|x - x0|`.

maxiter [int, optional] Maximum number of iterations.

fprime2 [callable, optional] The second order derivative of the function when available and convenient. If it is None (default), then the normal Newton-Raphson or the secant method is used. If it is not None, then Halley's method is used.

x1 [float, optional] Another estimate of the zero that should be somewhere near the actual zero. Used if *fprime* is not provided.

rtol [float, optional] Tolerance (relative) for termination.

full_output [bool, optional] If *full_output* is False (default), the root is returned. If True and *x0* is scalar, the return value is `(x, r)`, where `x` is the root and `r` is a *RootResults* object. If True and *x0* is non-scalar, the return value is `(x, converged, zero_der)` (see Returns section for details).

disp [bool, optional] If True, raise a RuntimeError if the algorithm didn't converge, with the error message containing the number of iterations and current function value. Otherwise, the convergence status is recorded in a `RootResults` return object. Ignored if *x0* is not scalar. *Note: this has little to do with displaying, however, the `disp` keyword cannot be renamed for backwards compatibility.*

Returns

root [float, sequence, or ndarray] Estimated location where function is zero.

r [`RootResults`, optional] Present if `full_output=True` and *x0* is scalar. Object containing information about the convergence. In particular, `r.converged` is True if the routine converged.

converged [ndarray of bool, optional] Present if `full_output=True` and *x0* is non-scalar. For vector functions, indicates which elements converged successfully.

zero_der [ndarray of bool, optional] Present if `full_output=True` and *x0* is non-scalar. For vector functions, indicates which elements had a zero derivative.

brentq, **brenth**, **ridder**, **bisect**

fsolve

find zeros in N dimensions.

Notes

The convergence rate of the Newton-Raphson method is quadratic, the Halley method is cubic, and the secant method is sub-quadratic. This means that if the function is well-behaved the actual error in the estimated zero after the nth iteration is approximately the square (cube for Halley) of the error after the (n-1)th step. However, the stopping criterion used here is the step size and there is no guarantee that a zero has been found. Consequently, the result should be verified. Safer algorithms are brentq, brenth, ridder, and bisect, but they all require that the root first be bracketed in an interval where the function changes sign. The brentq algorithm is recommended for general use in one dimensional problems when such an interval has been found.

When `newton` is used with arrays, it is best suited for the following types of problems:

- The initial guesses, *x0*, are all relatively the same distance from the roots.
- Some or all of the extra arguments, *args*, are also arrays so that a class of similar problems can be solved together.
- The size of the initial guesses, *x0*, is larger than O(100) elements. Otherwise, a naive loop may perform as well or better than a vector.

Examples

```
>>> from scipy import optimize
>>> import matplotlib.pyplot as plt
```

```
>>> def f(x):
...     return (x**3 - 1)  # only one real root at x = 1
```

`fprime` is not provided, use the secant method:

```
>>> root = optimize.newton(f, 1.5)
>>> root
1.0000000000000016
>>> root = optimize.newton(f, 1.5, fprime2=lambda x: 6 * x)
>>> root
1.0000000000000016
```

Only `fprime` is provided, use the Newton-Raphson method:

```
>>> root = optimize.newton(f, 1.5, fprime=lambda x: 3 * x**2)
>>> root
1.0
```

Both `fprime2` and `fprime` are provided, use Halley's method:

```
>>> root = optimize.newton(f, 1.5, fprime=lambda x: 3 * x**2,
...                        fprime2=lambda x: 6 * x)
>>> root
1.0
```

When we want to find zeros for a set of related starting values and/or function parameters, we can provide both of those as an array of inputs:

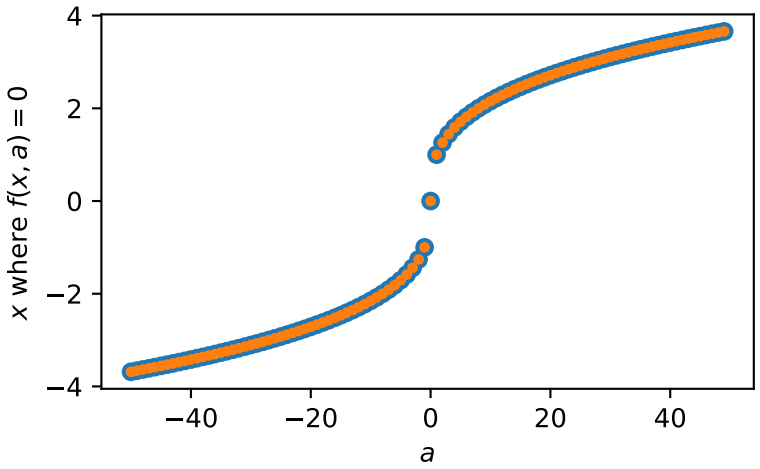
```
>>> f = lambda x, a: x**3 - a
>>> fder = lambda x, a: 3 * x**2
>>> rng = np.random.default_rng()
>>> x = rng.standard_normal(100)
>>> a = np.arange(-50, 50)
>>> vec_res = optimize.newton(f, x, fprime=fder, args=(a, ), maxiter=200)
```

The above is the equivalent of solving for each value in `(x, a)` separately in a for-loop, just faster:

```
>>> loop_res = [optimize.newton(f, x0, fprime=fder, args=(a0,))
...             for x0, a0 in zip(x, a)]
>>> np.allclose(vec_res, loop_res)
True
```

Plot the results found for all values of `a`:

```
>>> analytical_result = np.sign(a) * np.abs(a)**(1/3)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(a, analytical_result, 'o')
>>> ax.plot(a, vec_res, '.')
>>> ax.set_xlabel('$a$')
>>> ax.set_ylabel('$x$ where $f(x, a)=0$')
>>> plt.show()
```



scipy.optimize.toms748

`scipy.optimize.`**`toms748`**(*f*, *a*, *b*, *args=()*, *k=1*, *xtol=2e-12*, *rtol=8.881784197001252e-16*, *maxiter=100*, *full_output=False*, *disp=True*)

Find a zero using TOMS Algorithm 748 method.

Implements the Algorithm 748 method of Alefeld, Potro and Shi to find a zero of the function f on the interval *[a , b]*, where *f(a)* and *f(b)* must have opposite signs.

It uses a mixture of inverse cubic interpolation and "Newton-quadratic" steps. [APS1995].

Parameters

f [function] Python function returning a scalar. The function f must be continuous, and $f(a)$ and $f(b)$ have opposite signs.

a [scalar,] lower boundary of the search interval

b [scalar,] upper boundary of the search interval

args [tuple, optional] containing extra arguments for the function f. f is called by `f(x, *args)`.

k [int, optional] The number of Newton quadratic steps to perform each iteration. `k>=1`.

xtol [scalar, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root. The parameter must be non-negative.

rtol [scalar, optional] The computed root `x0` will satisfy `np.allclose(x, x0, atol=xtol, rtol=rtol)`, where `x` is the exact root.

maxiter [int, optional] If convergence is not achieved in *maxiter* iterations, an error is raised. Must be >= 0.

full_output

[bool, optional] If *full_output* is False, the root is returned. If *full_output* is True, the return value is `(x, r)`, where *x* is the root, and *r* is a *RootResults* object.

disp [bool, optional] If True, raise RuntimeError if the algorithm didn't converge. Otherwise, the convergence status is recorded in the *RootResults* return object.

Returns

x0 [float] Approximate Zero of f

r [*RootResults* (present if `full_output = True`)] Object containing information about the convergence. In particular, `r.converged` is True if the routine converged.

brentq, **brenth**, **ridder**, **bisect**, **newton**

fsolve

find zeroes in N dimensions.

Notes

f must be continuous. Algorithm 748 with `k=2` is asymptotically the most efficient algorithm known for finding roots of a four times continuously differentiable function. In contrast with Brent's algorithm, which may only decrease the length of the enclosing bracket on the last step, Algorithm 748 decreases it each iteration with the same asymptotic efficiency as it finds the root.

For easy statement of efficiency indices, assume that *f* has 4 continuouous deriviatives. For `k=1`, the convergence order is at least 2.7, and with about asymptotically 2 function evaluations per iteration, the efficiency index is approximately 1.65. For `k=2`, the order is about 4.6 with asymptotically 3 function evaluations per iteration, and the efficiency index 1.66. For higher values of *k*, the efficiency index approaches the kth root of `(3k-2)`, hence `k=1` or `k=2` are usually appropriate.

Examples

```
>>> def f(x):
...     return (x**3 - 1)  # only one real root at x = 1
```

```
>>> from scipy import optimize
>>> root, results = optimize.toms748(f, 0, 2, full_output=True)
>>> root
1.0
>>> results
      converged: True
           flag: 'converged'
 function_calls: 11
     iterations: 5
           root: 1.0
```

scipy.optimize.RootResults

class scipy.optimize.**RootResults**(*root*, *iterations*, *function_calls*, *flag*)

Represents the root finding result.

Attributes

root [float] Estimated root location.
iterations [int] Number of iterations needed to find the root.
function_calls [int] Number of times the function was called.

converged [bool] True if the routine converged.
flag [str] Description of the cause of termination.

The *root_scalar* function supports the following methods:

root_scalar(method='brentq')

scipy.optimize.**root_scalar**(*args=()*, *method='brentq'*, *x0=None*, *options={}*)

See also:

For documentation for the rest of the parameters, see *scipy.optimize.root_scalar*

Options

args [tuple, optional] Extra arguments passed to the objective function.
xtol [float, optional] Tolerance (absolute) for termination.
rtol [float, optional] Tolerance (relative) for termination.
maxiter [int, optional] Maximum number of iterations.
options: dict, optional
Specifies any method-specific options not covered above

root_scalar(method='brenth')

scipy.optimize.**root_scalar**(*args=()*, *method='brenth'*, *x0=None*, *options={}*)

See also:

For documentation for the rest of the parameters, see *scipy.optimize.root_scalar*

Options

args [tuple, optional] Extra arguments passed to the objective function.
xtol [float, optional] Tolerance (absolute) for termination.
rtol [float, optional] Tolerance (relative) for termination.
maxiter [int, optional] Maximum number of iterations.
options: dict, optional
Specifies any method-specific options not covered above.

root_scalar(method='bisect')

scipy.optimize.**root_scalar**(*args=()*, *method='bisect'*, *x0=None*, *options={}*)

See also:

For documentation for the rest of the parameters, see *scipy.optimize.root_scalar*

Options

args [tuple, optional] Extra arguments passed to the objective function.
xtol [float, optional] Tolerance (absolute) for termination.
rtol [float, optional] Tolerance (relative) for termination.
maxiter [int, optional] Maximum number of iterations.

options: dict, optional
Specifies any method-specific options not covered above.

root_scalar(method='ridder')

scipy.optimize.**root_scalar**(*args=()*, *method='ridder'*, *x0=None*, *options={}*)

See also:

For documentation for the rest of the parameters, see *scipy.optimize.root_scalar*

Options

args [tuple, optional] Extra arguments passed to the objective function.
xtol [float, optional] Tolerance (absolute) for termination.
rtol [float, optional] Tolerance (relative) for termination.
maxiter [int, optional] Maximum number of iterations.
options: dict, optional
Specifies any method-specific options not covered above.

root_scalar(method='newton')

scipy.optimize.**root_scalar**(*args=()*, *method='newton'*, *x0=None*, *options={}*)

See also:

For documentation for the rest of the parameters, see *scipy.optimize.root_scalar*

Options

args [tuple, optional] Extra arguments passed to the objective function and its derivative.
xtol [float, optional] Tolerance (absolute) for termination.
rtol [float, optional] Tolerance (relative) for termination.
maxiter [int, optional] Maximum number of iterations.
x0 [float, required] Initial guess.
fprime [bool or callable, optional] If *fprime* is a boolean and is True, f is assumed to return the value of derivative along with the objective function. *fprime* can also be a callable returning the derivative of f. In this case, it must accept the same arguments as f.
options: dict, optional
Specifies any method-specific options not covered above.

root_scalar(method='toms748')

scipy.optimize.**root_scalar**(*args=()*, *method='toms748'*, *x0=None*, *options={}*)

See also:

For documentation for the rest of the parameters, see *scipy.optimize.root_scalar*

Options

args [tuple, optional] Extra arguments passed to the objective function.

xtol [float, optional] Tolerance (absolute) for termination.
rtol [float, optional] Tolerance (relative) for termination.
maxiter [int, optional] Maximum number of iterations.
options: dict, optional
Specifies any method-specific options not covered above.

root_scalar(method='secant')

scipy.optimize.**root_scalar**(*args=()*, *method='secant'*, *x0=None*, *options={}*)

See also:

For documentation for the rest of the parameters, see *scipy.optimize.root_scalar*

Options

args [tuple, optional] Extra arguments passed to the objective function.
xtol [float, optional] Tolerance (absolute) for termination.
rtol [float, optional] Tolerance (relative) for termination.
maxiter [int, optional] Maximum number of iterations.
x0 [float, required] Initial guess.
x1 [float, required] A second guess.
options: dict, optional
Specifies any method-specific options not covered above.

root_scalar(method='halley')

scipy.optimize.**root_scalar**(*args=()*, *method='halley'*, *x0=None*, *options={}*)

See also:

For documentation for the rest of the parameters, see *scipy.optimize.root_scalar*

Options

args [tuple, optional] Extra arguments passed to the objective function and its derivatives.
xtol [float, optional] Tolerance (absolute) for termination.
rtol [float, optional] Tolerance (relative) for termination.
maxiter [int, optional] Maximum number of iterations.
x0 [float, required] Initial guess.
fprime [bool or callable, required] If *fprime* is a boolean and is True, f is assumed to return the value of derivative along with the objective function. *fprime* can also be a callable returning the derivative of f. In this case, it must accept the same arguments as f.
fprime2 [bool or callable, required] If *fprime2* is a boolean and is True, f is assumed to return the value of 1st and 2nd derivatives along with the objective function. *fprime2* can also be a callable returning the 2nd derivative of f. In this case, it must accept the same arguments as f.
options: dict, optional
Specifies any method-specific options not covered above.

The table below lists situations and appropriate methods, along with *asymptotic* convergence rates per iteration (and per function evaluation) for successful convergence to a simple root(*). Bisection is the slowest of them all, adding one bit of accuracy for each function evaluation, but is guaranteed to converge. The other bracketing methods all (eventually) increase the number of accurate bits by about 50% for every function evaluation. The derivative-based methods, all built on `newton`, can converge quite quickly if the initial value is close to the root. They can also be applied to functions defined on (a subset of) the complex plane.

Domain of f	Bracket?	Derivatives?		Solvers	Convergence	
		fprime	*fprime2*		Guaranteed?	Rate(s)(*)
R	Yes	N/A	N/A	• bisection • brentq • brenth • ridder • toms748	• Yes • Yes • Yes • Yes • Yes	• 1 "Linear" • >=1, <= 1.62 • >=1, <= 1.62 • 2.0 (1.41) • 2.7 (1.65)
R or *C*	No	No	No	secant	No	1.62 (1.62)
R or *C*	No	Yes	No	newton	No	2.00 (1.41)
R or *C*	No	Yes	Yes	halley	No	3.00 (1.44)

`scipy.optimize.cython_optimize` – Typed Cython versions of zeros functions

Fixed point finding:

`fixed_point`(func, x0[, args, xtol, maxiter, …])	Find a fixed point of the function.

scipy.optimize.fixed_point

scipy.optimize.**fixed_point**(*func*, *x0*, *args=()*, *xtol=1e-08*, *maxiter=500*, *method='del2'*)

Find a fixed point of the function.

Given a function of one or more variables and a starting point, find a fixed point of the function: i.e., where `func(x0) == x0`.

Parameters

func [function] Function to evaluate.
x0 [array_like] Fixed point of function.
args [tuple, optional] Extra arguments to *func*.
xtol [float, optional] Convergence tolerance, defaults to 1e-08.
maxiter [int, optional] Maximum number of iterations, defaults to 500.
method [{"del2", "iteration"}, optional] Method of finding the fixed-point, defaults to "del2", which uses Steffensen's Method with Aitken's `Del^2` convergence acceleration [1]. The "iteration" method simply iterates the function until convergence is detected, without attempting

to accelerate the convergence.

References

[1]

Examples

```
>>> from scipy import optimize
>>> def func(x, c1, c2):
...     return np.sqrt(c1/(x+c2))
>>> c1 = np.array([10,12.])
>>> c2 = np.array([3, 5.])
>>> optimize.fixed_point(func, [1.2, 1.3], args=(c1,c2))
array([ 1.4920333 ,  1.37228132])
```

Multidimensional

root(fun, x0[, args, method, jac, tol, …])	Find a root of a vector function.

scipy.optimize.root

scipy.optimize.**root**(*fun*, *x0*, *args=()*, *method='hybr'*, *jac=None*, *tol=None*, *callback=None*, *options=None*)

Find a root of a vector function.

Parameters

fun [callable] A vector function to find a root of.

x0 [ndarray] Initial guess.

args [tuple, optional] Extra arguments passed to the objective function and its Jacobian.

method [str, optional] Type of solver. Should be one of

- 'hybr' *(see here)*
- 'lm' *(see here)*
- 'broyden1' *(see here)*
- 'broyden2' *(see here)*
- 'anderson' *(see here)*
- 'linearmixing' *(see here)*
- 'diagbroyden' *(see here)*
- 'excitingmixing' *(see here)*
- 'krylov' *(see here)*
- 'df-sane' *(see here)*

jac [bool or callable, optional] If *jac* is a Boolean and is True, *fun* is assumed to return the value of Jacobian along with the objective function. If False, the Jacobian will be estimated numerically. *jac* can also be a callable returning the Jacobian of *fun*. In this case, it must accept the same arguments as *fun*.

tol [float, optional] Tolerance for termination. For detailed control, use solver-specific options.

callback [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where *x* is the current solution and *f* the corresponding residual. For all methods but 'hybr' and 'lm'.

options [dict, optional] A dictionary of solver options. E.g., *xtol* or *maxiter*, see `show_options()` for details.

Returns

sol [OptimizeResult] The solution represented as a `OptimizeResult` object. Important attributes are: `x` the solution array, `success` a Boolean flag indicating if the algorithm exited successfully and `message` which describes the cause of the termination. See `OptimizeResult` for a description of other attributes.

See also:

`show_options`

Additional options accepted by the solvers

Notes

This section describes the available solvers that can be selected by the 'method' parameter. The default method is *hybr*.

Method *hybr* uses a modification of the Powell hybrid method as implemented in MINPACK [1].

Method *lm* solves the system of nonlinear equations in a least squares sense using a modification of the Levenberg-Marquardt algorithm as implemented in MINPACK [1].

Method *df-sane* is a derivative-free spectral method. [3]

Methods *broyden1*, *broyden2*, *anderson*, *linearmixing*, *diagbroyden*, *excitingmixing*, *krylov* are inexact Newton methods, with backtracking or full line searches [2]. Each method corresponds to a particular Jacobian approximations. See `nonlin` for details.

- Method *broyden1* uses Broyden's first Jacobian approximation, it is known as Broyden's good method.
- Method *broyden2* uses Broyden's second Jacobian approximation, it is known as Broyden's bad method.
- Method *anderson* uses (extended) Anderson mixing.
- Method *Krylov* uses Krylov approximation for inverse Jacobian. It is suitable for large-scale problem.
- Method *diagbroyden* uses diagonal Broyden Jacobian approximation.
- Method *linearmixing* uses a scalar Jacobian approximation.
- Method *excitingmixing* uses a tuned diagonal Jacobian approximation.

Warning: The algorithms implemented for methods *diagbroyden*, *linearmixing* and *excitingmixing* may be useful for specific problems, but whether they will work may depend strongly on the problem.

New in version 0.11.0.

[1], [2], [3]

Examples

The following functions define a system of nonlinear equations and its jacobian.

```
>>> def fun(x):
...     return [x[0]  + 0.5 * (x[0] - x[1])**3 - 1.0,
...             0.5 * (x[1] - x[0])**3 + x[1]]
```

```
>>> def jac(x):
...     return np.array([[1 + 1.5 * (x[0] - x[1])**2,
...                       -1.5 * (x[0] - x[1])**2],
...                      [-1.5 * (x[1] - x[0])**2,
...                       1 + 1.5 * (x[1] - x[0])**2]])
```

A solution can be obtained as follows.

```
>>> from scipy import optimize
>>> sol = optimize.root(fun, [0, 0], jac=jac, method='hybr')
>>> sol.x
array([ 0.8411639,  0.1588361])
```

The *root* function supports the following methods:

root(method='hybr')

scipy.optimize.**root**(*fun*, *x0*, *args=()*, *method='hybr'*, *jac=None*, *tol=None*, *callback=None*, *options={'func': None, 'col_deriv': 0, 'xtol': 1.49012e-08, 'maxfev': 0, 'band': None, 'eps': None, 'factor': 100, 'diag': None}*)

Find the roots of a multivariate function using MINPACK's hybrd and hybrj routines (modified Powell method).

See also:

For documentation for the rest of the parameters, see *scipy.optimize.root*

Options

col_deriv [bool] Specify whether the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).

xtol [float] The calculation will terminate if the relative error between two consecutive iterates is at most *xtol*.

maxfev [int] The maximum number of calls to the function. If zero, then `100*(N+1)` is the maximum where N is the number of elements in *x0*.

band [tuple] If set to a two-sequence containing the number of sub- and super-diagonals within the band of the Jacobi matrix, the Jacobi matrix is considered banded (only for `fprime=None`).

eps [float] A suitable step length for the forward-difference approximation of the Jacobian (for `fprime=None`). If *eps* is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision.

factor [float] A parameter determining the initial step bound (`factor * || diag * x||`). Should be in the interval `(0.1, 100)`.

diag [sequence] N positive entries that serve as a scale factors for the variables.

root(method='lm')

scipy.optimize.**root**(*fun*, *x0*, *args=()*, *method='lm'*, *jac=None*, *tol=None*, *callback=None*, *options={'col_deriv': 0, 'xtol': 1.49012e-08, 'ftol': 1.49012e-08, 'gtol': 0.0, 'maxiter': 0, 'eps': 0.0, 'factor': 100, 'diag': None}*)

Solve for least squares with Levenberg-Marquardt

See also:

For documentation for the rest of the parameters, see *scipy.optimize.root*

Options

col_deriv [bool] non-zero to specify that the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).
ftol [float] Relative error desired in the sum of squares.
xtol [float] Relative error desired in the approximate solution.
gtol [float] Orthogonality desired between the function vector and the columns of the Jacobian.
maxiter [int] The maximum number of calls to the function. If zero, then 100*(N+1) is the maximum where N is the number of elements in x0.
epsfcn [float] A suitable step length for the forward-difference approximation of the Jacobian (for Dfun=None). If epsfcn is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision.
factor [float] A parameter determining the initial step bound (`factor * || diag * x||`). Should be in interval `(0.1, 100)`.
diag [sequence] N positive entries that serve as a scale factors for the variables.

root(method='broyden1')

scipy.optimize.**root**(*fun*, *x0*, *args=()*, *method='broyden1'*, *tol=None*, *callback=None*, *options={}*)

See also:

For documentation for the rest of the parameters, see *scipy.optimize.root*

Options

nit [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
disp [bool, optional] Print status to stdout on every iteration.
maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.
ftol [float, optional] Relative tolerance for the residual. If omitted, not used.
fatol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
xtol [float, optional] Relative minimum step size. If omitted, not used.
xatol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search
[{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

jac_options
[dict, optional]
Options for the respective Jacobian approximation.

alpha [float, optional] Initial guess for the Jacobian is (-1/alpha).

reduction_method
[str or tuple, optional] Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form `(method, param1, param2, ...)` that gives the name of the method and values for additional parameters.
Methods available:

- **restart** Drop all matrix columns. Has no extra parameters.
- **simple** Drop oldest matrix column. Has no extra parameters.
- **svd** Keep only the most significant SVD components.
  Extra parameters:
  – to_retain
  Number of SVD components to retain when rank reduction is done. Default is `max_rank - 2`.

max_rank [int, optional] Maximum rank for the Broyden matrix. Default is infinity (i.e., no rank reduction).

root(method='broyden2')

`scipy.optimize.`**`root`**(*fun*, *x0*, *args=()*, *method='broyden2'*, *tol=None*, *callback=None*, *options={}*)

See also:

line_search
[{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.
jac_options
[dict, optional] Options for the respective Jacobian approximation.
alpha [float, optional] Initial guess for the Jacobian is (-1/alpha).
M [float, optional] Number of previous vectors to retain. Defaults to 5.
w0 [float, optional] Regularization parameter for numerical stability. Compared to unity, good values of the order of 0.01.

root(method='linearmixing')

scipy.optimize.**root**(*fun*, *x0*, *args=()*, *method='linearmixing'*, *tol=None*, *callback=None*, *options={}*)

See also:

For documentation for the rest of the parameters, see *scipy.optimize.root*

Options

nit [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

disp [bool, optional] Print status to stdout on every iteration.

maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.

ftol [float, optional] Relative tolerance for the residual. If omitted, not used.

fatol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

xtol [float, optional] Relative minimum step size. If omitted, not used.

xatol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search

[{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

jac_options

[dict, optional] Options for the respective Jacobian approximation.

alpha [float, optional] initial guess for the jacobian is (-1/alpha).

root(method='diagbroyden')

scipy.optimize.**root**(*fun*, *x0*, *args=()*, *method='diagbroyden'*, *tol=None*, *callback=None*, *options={}*)

For documentation for the rest of the parameters, see *scipy.optimize.root*

Options

nit [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

disp [bool, optional] Print status to stdout on every iteration.

maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.

ftol [float, optional] Relative tolerance for the residual. If omitted, not used.

fatol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

xtol [float, optional] Relative minimum step size. If omitted, not used.

xatol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search
[{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

jac_options
[dict, optional] Options for the respective Jacobian approximation.

alpha [float, optional] initial guess for the jacobian is (-1/alpha).

root(method='excitingmixing')

scipy.optimize.**root**(*fun*, *x0*, *args=()*, *method='excitingmixing'*, *tol=None*, *callback=None*, *options={}*)

See also:

For documentation for the rest of the parameters, see *scipy.optimize.root*

Options

nit [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

disp [bool, optional] Print status to stdout on every iteration.

maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.

ftol [float, optional] Relative tolerance for the residual. If omitted, not used.

fatol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

xtol [float, optional] Relative minimum step size. If omitted, not used.

xatol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search
[{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

jac_options
[dict, optional] Options for the respective Jacobian approximation.

alpha [float, optional] Initial Jacobian approximation is (-1/alpha).

alphamax [float, optional] The entries of the diagonal Jacobian are kept in the range `[alpha, alphamax]`.

root(method='krylov')

scipy.optimize.**root**(*fun*, *x0*, *args=()*, *method='krylov'*, *tol=None*, *callback=None*, *options={}*)

See also:

For documentation for the rest of the parameters, see *scipy.optimize.root*

Options

nit [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
disp [bool, optional] Print status to stdout on every iteration.
maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.
ftol [float, optional] Relative tolerance for the residual. If omitted, not used.
fatol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
xtol [float, optional] Relative minimum step size. If omitted, not used.
xatol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
line_search
[{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.
jac_options
[dict, optional] Options for the respective Jacobian approximation.
rdiff [float, optional] Relative step size to use in numerical differentiation.
method [{'lgmres', 'gmres', 'bicgstab', 'cgs', 'minres'} or function] Krylov method to use to approximate the Jacobian. Can be a string, or a function implementing the same interface as the iterative solvers in *scipy.sparse.linalg*. The default is *scipy.sparse.linalg.lgmres*.
inner_M [LinearOperator or InverseJacobian] Preconditioner for the inner Krylov iteration. Note that you can use also inverse Jacobians as (adaptive) preconditioners. For example,

```
>>> jac = BroydenFirst()
>>> kjac = KrylovJacobian(inner_M=jac.inverse).
```

If the preconditioner has a method named 'update', it will be called as `update(x, f)` after each nonlinear step, with `x` giving the current point, and `f` the current function value.
inner_tol, inner_maxiter, …
Parameters to pass on to the "inner" Krylov solver. See *scipy.sparse.linalg.gmres* for details.
outer_k [int, optional] Size of the subspace kept across LGMRES nonlinear iterations. See *scipy.sparse.linalg.lgmres* for details.

root(method='df-sane')

scipy.optimize.**root**(*fun*, *x0*, *args=()*, *method='df-sane'*, *tol=None*, *callback=None*, *options={'func': None, 'ftol': 1e-08, 'fatol': 1e-300, 'maxfev': 1000, 'fnorm': None, 'disp': False, 'M': 10, 'eta_strategy': None, 'sigma_eps': 1e-10, 'sigma_0': 1.0, 'line_search': 'cruz'}*)

Solve nonlinear equation with the DF-SANE method

See also:

For documentation for the rest of the parameters, see *scipy.optimize.root*

Options

ftol [float, optional] Relative norm tolerance.

fatol [float, optional] Absolute norm tolerance. Algorithm terminates when `||func(x)|| < fatol + ftol ||func(x_0)||`.

fnorm [callable, optional] Norm to use in the convergence check. If None, 2-norm is used.

maxfev [int, optional] Maximum number of function evaluations.

disp [bool, optional] Whether to print convergence process to stdout.

eta_strategy [callable, optional] Choice of the `eta_k` parameter, which gives slack for growth of `||F||**2`. Called as `eta_k = eta_strategy(k, x, F)` with *k* the iteration number, *x* the current iterate and *F* the current residual. Should satisfy `eta_k > 0` and `sum(eta, k=0..inf) < inf`. Default: `||F||**2 / (1 + k)**2`.

sigma_eps [float, optional] The spectral coefficient is constrained to `sigma_eps < sigma < 1/sigma_eps`. Default: 1e-10

sigma_0 [float, optional] Initial spectral coefficient. Default: 1.0

M [int, optional] Number of iterates to include in the nonmonotonic line search. Default: 10

line_search [{'cruz', 'cheng'}] Type of line search to employ. 'cruz' is the original one defined in [Martinez & Raydan. Math. Comp. 75, 1429 (2006)], 'cheng' is a modified search defined in [Cheng & Li. IMA J. Numer. Anal. 29, 814 (2009)]. Default: 'cruz'

Linear programming

linprog(c[, A_ub, b_ub, A_eq, b_eq, bounds, …])	Linear programming: minimize a linear objective function subject to linear equality and inequality constraints.

scipy.optimize.linprog

scipy.optimize.**linprog**(*c*, *A_ub=None*, *b_ub=None*, *A_eq=None*, *b_eq=None*, *bounds=None*, *method='interior-point'*, *callback=None*, *options=None*, *x0=None*)

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints.

Linear programming solves problems of the following form:

$$\begin{aligned} \min_x \ & c^T x \\ \text{such that } & A_{ub} x \leq b_{ub}, \\ & A_{eq} x = b_{eq}, \\ & l \leq x \leq u, \end{aligned}$$

where x is a vector of decision variables; c, b_{ub}, b_{eq}, l, and u are vectors; and A_{ub} and A_{eq} are matrices.

Alternatively, that's:

minimize:

```
c @ x
```

such that:

```
A_ub @ x <= b_ub
A_eq @ x == b_eq
lb <= x <= ub
```

Note that by default `lb = 0` and `ub = None` unless specified with `bounds`.

Parameters

c [1-D array] The coefficients of the linear objective function to be minimized.

A_ub [2-D array, optional] The inequality constraint matrix. Each row of `A_ub` specifies the coefficients of a linear inequality constraint on `x`.

b_ub [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of `A_ub @ x`.

A_eq [2-D array, optional] The equality constraint matrix. Each row of `A_eq` specifies the coefficients of a linear equality constraint on `x`.

b_eq [1-D array, optional] The equality constraint vector. Each element of `A_eq @ x` must equal the corresponding element of `b_eq`.

bounds [sequence, optional] A sequence of `(min, max)` pairs for each element in `x`, defining the minimum and maximum values of that decision variable. Use `None` to indicate that there is no bound. By default, bounds are `(0, None)` (all decision variables are non-negative). If a single tuple `(min, max)` is provided, then `min` and `max` will serve as bounds for all decision variables.

method [str, optional] The algorithm used to solve the standard form problem. *'highs-ds'*, *'highs-ipm'*, *'highs'*, *'interior-point'* (default), *'revised simplex'*, and *'simplex'* (legacy) are supported.

callback [callable, optional] If a callback function is provided, it will be called at least once per iteration of the algorithm. The callback function must accept a single *scipy.optimize.OptimizeResult* consisting of the following fields:

- **x** [1-D array] The current solution vector.
- **fun** [float] The current value of the objective function `c @ x`.
- **success** [bool] `True` when the algorithm has completed successfully.
- **slack** [1-D array] The (nominally positive) values of the slack, `b_ub - A_ub @ x`.
- **con** [1-D array] The (nominally zero) residuals of the equality constraints, `b_eq - A_eq @ x`.
- **phase** [int] The phase of the algorithm being executed.
- **status** [int] An integer representing the status of the algorithm.
  - `0` : Optimization proceeding nominally.
  - `1` : Iteration limit reached.
  - `2` : Problem appears to be infeasible.
  - `3` : Problem appears to be unbounded.
  - `4` : Numerical difficulties encountered.
- **nit** [int] The current iteration number.
- **message** [str] A string descriptor of the algorithm status.

Callback functions are not currently supported by the HiGHS methods.

options [dict, optional] A dictionary of solver options. All methods accept the following options:

- **maxiter** [int] Maximum number of iterations to perform. Default: see method-specific documentation.
- **disp** [bool] Set to `True` to print convergence messages. Default: `False`.
- **presolve** [bool] Set to `False` to disable automatic presolve. Default: `True`.

All methods except the HiGHS solvers also accept:

- **tol** [float] A tolerance which determines when a residual is "close enough" to zero to be considered exactly zero.

autoscale [bool] Set to `True` to automatically perform equilibration. Consider using this option if the numerical values in the constraints are separated by several orders of magnitude. Default: `False`.

rr [bool] Set to `False` to disable automatic redundancy removal. Default: `True`.

rr_method

[string] Method used to identify and remove redundant rows from the equality constraint matrix after presolve. For problems with dense input, the available methods for redundancy removal are:

"SVD": Repeatedly performs singular value decomposition on the matrix, detecting redundant rows based on nonzeros in the left singular vectors that correspond with zero singular values. May be fast when the matrix is nearly full rank.

"pivot": Uses the algorithm presented in [5] to identify redundant rows.

"ID": Uses a randomized interpolative decomposition. Identifies columns of the matrix transpose not used in a full-rank interpolative decomposition of the matrix.

None: Uses "svd" if the matrix is nearly full rank, that is, the difference between the matrix rank and the number of rows is less than five. If not, uses "pivot". The behavior of this default is subject to change without prior notice.

Default: None. For problems with sparse input, this option is ignored, and the pivot-based algorithm presented in [5] is used.

For method-specific options, see *show_options('linprog')*.

x0 [1-D array, optional] Guess values of the decision variables, which will be refined by the optimization algorithm. This argument is currently used only by the 'revised simplex' method, and can only be used if *x0* represents a basic feasible solution.

Returns

res [OptimizeResult] A *scipy.optimize.OptimizeResult* consisting of the fields:

x [1-D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.

fun [float] The optimal value of the objective function `c @ x`.

slack [1-D array] The (nominally positive) values of the slack variables, `b_ub - A_ub @ x`.

con [1-D array] The (nominally zero) residuals of the equality constraints, `b_eq - A_eq @ x`.

success [bool] `True` when the algorithm succeeds in finding an optimal solution.

status [int] An integer representing the exit status of the algorithm.

`0` : Optimization terminated successfully.

`1` : Iteration limit reached.

`2` : Problem appears to be infeasible.

`3` : Problem appears to be unbounded.

`4` : Numerical difficulties encountered.

nit [int] The total number of iterations performed in all phases.

message [str] A string descriptor of the exit status of the algorithm.

show_options

Additional options accepted by the solvers.

Notes

This section describes the available solvers that can be selected by the 'method' parameter.

'highs-ds' and *'highs-ipm'* are interfaces to the HiGHS simplex and interior-point method solvers [13], respectively. *'highs'* chooses between the two automatically. These are the fastest linear programming solvers in SciPy, especially for large, sparse problems; which of these two is faster is problem-dependent. *'interior-point'* is the default as it was the fastest and most robust method before the recent addition of the HiGHS solvers. *'revised simplex'* is more accurate than interior-point for the problems it solves. *'simplex'* is the legacy method and is included for backwards compatibility and educational purposes.

Method *highs-ds* is a wrapper of the C++ high performance dual revised simplex implementation (HSOL) [13], [14]. Method *highs-ipm* is a wrapper of a C++ implementation of an **i**nterior-**p**oint **m**ethod [13]; it features a crossover routine, so it is as accurate as a simplex solver. Method *highs* chooses between the two automatically. For new code involving `linprog`, we recommend explicitly choosing one of these three method values.

New in version 1.6.0.

Method *interior-point* uses the primal-dual path following algorithm as outlined in [4]. This algorithm supports sparse constraint matrices and is typically faster than the simplex methods, especially for large, sparse problems. Note, however, that the solution returned may be slightly less accurate than those of the simplex methods and will not, in general, correspond with a vertex of the polytope defined by the constraints.

New in version 1.0.0.

Method *revised simplex* uses the revised simplex method as described in [9], except that a factorization [11] of the basis matrix, rather than its inverse, is efficiently maintained and used to solve the linear systems at each iteration of the algorithm.

New in version 1.3.0.

Method *simplex* uses a traditional, full-tableau implementation of Dantzig's simplex algorithm [1], [2] (*not* the Nelder-Mead simplex). This algorithm is included for backwards compatibility and educational purposes.

New in version 0.15.0.

Before applying *interior-point*, *revised simplex*, or *simplex*, a presolve procedure based on [8] attempts to identify trivial infeasibilities, trivial unboundedness, and potential problem simplifications. Specifically, it checks for:

- rows of zeros in `A_eq` or `A_ub`, representing trivial constraints;
- columns of zeros in `A_eq` *and* `A_ub`, representing unconstrained variables;
- column singletons in `A_eq`, representing fixed variables; and
- column singletons in `A_ub`, representing simple bounds.

If presolve reveals that the problem is unbounded (e.g. an unconstrained and unbounded variable has negative cost) or infeasible (e.g., a row of zeros in `A_eq` corresponds with a nonzero in `b_eq`), the solver terminates with the appropriate status code. Note that presolve terminates as soon as any sign of unboundedness is detected; consequently, a problem may be reported as unbounded when in reality the problem is infeasible (but infeasibility has not been detected yet). Therefore, if it is important to know whether the problem is actually infeasible, solve the problem again with option `presolve=False`.

If neither infeasibility nor unboundedness are detected in a single pass of the presolve, bounds are tightened where possible and fixed variables are removed from the problem. Then, linearly dependent rows of the `A_eq` matrix are removed, (unless they represent an infeasibility) to avoid numerical difficulties in the primary solve routine. Note that rows that are nearly linearly dependent (within a prescribed tolerance) may also be removed, which can change the optimal solution in rare cases. If this is a concern, eliminate redundancy from your problem formulation and run with option `rr=False` or `presolve=False`.

Several potential improvements can be made here: additional presolve checks outlined in [8] should be implemented, the presolve routine should be run multiple times (until no further simplifications can be made), and more of the efficiency improvements from [5] should be implemented in the redundancy removal routines.

After presolve, the problem is transformed to standard form by converting the (tightened) simple bounds to upper bound constraints, introducing non-negative slack variables for inequality constraints, and expressing unbounded variables as the difference between two non-negative variables. Optionally, the problem is automatically scaled via equilibration [12]. The selected algorithm solves the standard form problem, and a postprocessing routine converts the result to a solution to the original problem.

References

[1], [2], [3], [4], [5], [6], [7], [8], [9], [10], [11], [12], [13], [14]

Examples

Consider the following problem:

$$\begin{aligned} \min_{x_0, x_1} \quad & -x_0 + 4x_1 \\ \text{such that} \quad & -3x_0 + x_1 \leq 6, \\ & -x_0 - 2x_1 \geq -4, \\ & x_1 \geq -3. \end{aligned}$$

The problem is not presented in the form accepted by *linprog*. This is easily remedied by converting the "greater than" inequality constraint to a "less than" inequality constraint by multiplying both sides by a factor of -1. Note also that the last constraint is really the simple bound $-3 \leq x_1 \leq \infty$. Finally, since there are no bounds on x_0, we must explicitly specify the bounds $-\infty \leq x_0 \leq \infty$, as the default is for variables to be non-negative. After collecting coeffecients into arrays and tuples, the input for this problem is:

```
>>> c = [-1, 4]
>>> A = [[-3, 1], [1, 2]]
>>> b = [6, 4]
>>> x0_bounds = (None, None)
>>> x1_bounds = (-3, None)
>>> from scipy.optimize import linprog
>>> res = linprog(c, A_ub=A, b_ub=b, bounds=[x0_bounds, x1_bounds])
```

Note that the default method for *linprog* is 'interior-point', which is approximate by nature.

```
>>> print(res)
     con: array([], dtype=float64)
     fun: -21.99999984082494 # may vary
 message: 'Optimization terminated successfully.'
     nit: 6 # may vary
   slack: array([3.89999997e+01, 8.46872439e-08] # may vary
  status: 0
 success: True
       x: array([ 9.99999989, -2.99999999]) # may vary
```

If you need greater accuracy, try 'revised simplex'.

```
>>> res = linprog(c, A_ub=A, b_ub=b, bounds=[x0_bounds, x1_bounds],␣
↪method='revised simplex')
>>> print(res)
     con: array([], dtype=float64)
     fun: -22.0 # may vary
 message: 'Optimization terminated successfully.'
     nit: 1 # may vary
   slack: array([39.,  0.]) # may vary
  status: 0
 success: True
       x: array([10., -3.]) # may vary
```

The *linprog* function supports the following methods:

linprog(method='simplex')

scipy.optimize.**linprog**(*c*, *A_ub=None*, *b_ub=None*, *A_eq=None*, *b_eq=None*, *bounds=None*, *method='simplex'*, *callback=None*, *options={'maxiter': 5000, 'disp': False, 'presolve': True, 'tol': 1e-12, 'autoscale': False, 'rr': True, 'bland': False}*, *x0=None*)

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using the tableau-based simplex method.

Linear programming solves problems of the following form:

$$\begin{aligned} \min_x \ & c^T x \\ \text{such that } & A_{ub} x \leq b_{ub}, \\ & A_{eq} x = b_{eq}, \\ & l \leq x \leq u, \end{aligned}$$

where x is a vector of decision variables; c, b_{ub}, b_{eq}, l, and u are vectors; and A_{ub} and A_{eq} are matrices.

Alternatively, that's:

minimize:

```
c @ x
```

such that:

```
A_ub @ x <= b_ub
A_eq @ x == b_eq
lb <= x <= ub
```

Note that by default `lb = 0` and `ub = None` unless specified with `bounds`.

Parameters

c [1-D array] The coefficients of the linear objective function to be minimized.

A_ub [2-D array, optional] The inequality constraint matrix. Each row of `A_ub` specifies the coefficients of a linear inequality constraint on `x`.

b_ub [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of `A_ub @ x`.

A_eq [2-D array, optional] The equality constraint matrix. Each row of `A_eq` specifies the coefficients of a linear equality constraint on `x`.

b_eq [1-D array, optional] The equality constraint vector. Each element of `A_eq @ x` must equal the corresponding element of `b_eq`.

bounds [sequence, optional] A sequence of `(min, max)` pairs for each element in `x`, defining the minimum and maximum values of that decision variable. Use `None` to indicate that there is no bound. By default, bounds are `(0, None)` (all decision variables are non-negative). If a single tuple `(min, max)` is provided, then `min` and `max` will serve as bounds for all decision variables.

method [str] This is the method-specific documentation for 'simplex'. *'highs'*, *'highs-ds'*, *'highs-ipm'*, *'interior-point'* (default), and *'revised simplex'* are also available.

callback [callable, optional] Callback function to be executed once per iteration.

Returns

res [OptimizeResult] A *scipy.optimize.OptimizeResult* consisting of the fields:

- **x** [1-D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
- **fun** [float] The optimal value of the objective function `c @ x`.
- **slack** [1-D array] The (nominally positive) values of the slack variables, `b_ub - A_ub @ x`.
- **con** [1-D array] The (nominally zero) residuals of the equality constraints, `b_eq - A_eq @ x`.
- **success** [bool] `True` when the algorithm succeeds in finding an optimal solution.
- **status** [int] An integer representing the exit status of the algorithm.
  `0` : Optimization terminated successfully.
  `1` : Iteration limit reached.
  `2` : Problem appears to be infeasible.
  `3` : Problem appears to be unbounded.
  `4` : Numerical difficulties encountered.
- **message** [str] A string descriptor of the exit status of the algorithm.
- **nit** [int] The total number of iterations performed in all phases.

See also:

For documentation for the rest of the parameters, see *scipy.optimize.linprog*

Options

maxiter [int (default: 5000)] The maximum number of iterations to perform in either phase.

disp [bool (default: False)] Set to `True` if indicators of optimization status are to be printed to the console each iteration.

presolve [bool (default: True)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting `True`; set to `False` if presolve is to be disabled.

tol [float (default: 1e-12)] The tolerance which determines when a solution is "close enough" to zero in Phase 1 to be considered a basic feasible solution or close enough to positive to serve as an optimal solution.

autoscale [bool (default: False)] Set to `True` to automatically perform equilibration. Consider using this option if the numerical values in the constraints are separated by several orders of magnitude.

rr [bool (default: True)] Set to `False` to disable automatic redundancy removal.

bland [bool] If True, use Bland's anti-cycling rule [3] to choose pivots to prevent cycling. If False, choose pivots which should lead to a converged solution more quickly. The latter method is subject to cycling (non-convergence) in rare instances.

unknown_options
[dict] Optional arguments not used by this particular solver. If *unknown_options* is non-empty a warning is issued listing all unused options.

linprog(method='interior-point')

scipy.optimize.**linprog**(*c*, *A_ub=None*, *b_ub=None*, *A_eq=None*, *b_eq=None*, *bounds=None*, *method='interior-point'*, *callback=None*, *options={'maxiter': 1000, 'disp': False, 'presolve': True, 'tol': 1e-08, 'autoscale': False, 'rr': True, 'alpha0': 0.99995, 'beta': 0.1, 'sparse': False, 'lstsq': False, 'sym_pos': True, 'cholesky': True, 'pc': True, 'ip': False, 'permc_spec': 'MMD_AT_PLUS_A'}*, *x0=None*)

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using the interior-point method of [4].

Linear programming solves problems of the following form:

$$\min_x c^T x$$
$$\text{such that } A_{ub} x \leq b_{ub},$$
$$A_{eq} x = b_{eq},$$
$$l \leq x \leq u,$$

where x is a vector of decision variables; c, b_{ub}, b_{eq}, l, and u are vectors; and A_{ub} and A_{eq} are matrices.

Alternatively, that's:

minimize:

```
c @ x
```

such that:

```
A_ub @ x <= b_ub
A_eq @ x == b_eq
lb <= x <= ub
```

Note that by default `lb = 0` and `ub = None` unless specified with `bounds`.

Parameters

c [1-D array] The coefficients of the linear objective function to be minimized.

A_ub [2-D array, optional] The inequality constraint matrix. Each row of `A_ub` specifies the coefficients of a linear inequality constraint on `x`.

b_ub [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of `A_ub @ x`.

A_eq [2-D array, optional] The equality constraint matrix. Each row of `A_eq` specifies the coefficients of a linear equality constraint on `x`.

b_eq [1-D array, optional] The equality constraint vector. Each element of `A_eq @ x` must equal the corresponding element of `b_eq`.

bounds [sequence, optional] A sequence of `(min, max)` pairs for each element in `x`, defining the minimum and maximum values of that decision variable. Use `None` to indicate that there is no bound. By default, bounds are `(0, None)` (all decision variables are non-negative). If a single tuple `(min, max)` is provided, then `min` and `max` will serve as bounds for all decision variables.

method [str] This is the method-specific documentation for 'interior-point'. *'highs'*, *'highs-ds'*, *'highs-ipm'*, *'revised simplex'*, and *'simplex'* (legacy) are also available.

callback [callable, optional] Callback function to be executed once per iteration.

Returns

res [OptimizeResult] A *scipy.optimize.OptimizeResult* consisting of the fields:

- **x** [1-D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
- **fun** [float] The optimal value of the objective function `c @ x`.
- **slack** [1-D array] The (nominally positive) values of the slack variables, `b_ub - A_ub @ x`.
- **con** [1-D array] The (nominally zero) residuals of the equality constraints, `b_eq - A_eq @ x`.
- **success** [bool] `True` when the algorithm succeeds in finding an optimal solution.
- **status** [int] An integer representing the exit status of the algorithm.
  `0` : Optimization terminated successfully.
  `1` : Iteration limit reached.
  `2` : Problem appears to be infeasible.
  `3` : Problem appears to be unbounded.
  `4` : Numerical difficulties encountered.
- **message** [str] A string descriptor of the exit status of the algorithm.
- **nit** [int] The total number of iterations performed in all phases.

See also:

For documentation for the rest of the parameters, see *scipy.optimize.linprog*

Options

- **maxiter** [int (default: 1000)] The maximum number of iterations of the algorithm.
- **disp** [bool (default: False)] Set to `True` if indicators of optimization status are to be printed to the console each iteration.
- **presolve** [bool (default: True)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting `True`; set to `False` if presolve is to be disabled.
- **tol** [float (default: 1e-8)] Termination tolerance to be used for all termination criteria; see [4] Section 4.5.
- **autoscale** [bool (default: False)] Set to `True` to automatically perform equilibration. Consider using this option if the numerical values in the constraints are separated by several orders of magnitude.
- **rr** [bool (default: True)] Set to `False` to disable automatic redundancy removal.
- **alpha0** [float (default: 0.99995)] The maximal step size for Mehrota's predictor-corrector search direction; see β_3 of [4] Table 8.1.
- **beta** [float (default: 0.1)] The desired reduction of the path parameter μ (see [6]) when Mehrota's predictor-corrector is not in use (uncommon).
- **sparse** [bool (default: False)] Set to `True` if the problem is to be treated as sparse after presolve. If either `A_eq` or `A_ub` is a sparse matrix, this option will automatically be set `True`, and the problem will be treated as sparse even during presolve. If your constraint matrices contain mostly zeros and the problem is not very small (less than about 100 constraints or variables), consider setting `True` or providing `A_eq` and `A_ub` as sparse matrices.
- **lstsq** [bool (default: `False`)] Set to `True` if the problem is expected to be very poorly conditioned. This should always be left `False` unless severe numerical difficulties are encountered. Leave this at the default unless you receive a warning message suggesting otherwise.
- **sym_pos** [bool (default: True)] Leave `True` if the problem is expected to yield a well conditioned symmetric positive definite normal equation matrix (almost always). Leave this at the default unless you receive a warning message suggesting otherwise.
- **cholesky** [bool (default: True)] Set to `True` if the normal equations are to be solved by explicit Cholesky decomposition followed by explicit forward/backward substitution. This is typically faster for problems that are numerically well-behaved.

pc [bool (default: True)] Leave `True` if the predictor-corrector method of Mehrota is to be used. This is almost always (if not always) beneficial.

ip [bool (default: False)] Set to `True` if the improved initial point suggestion due to [4] Section 4.3 is desired. Whether this is beneficial or not depends on the problem.

permc_spec
[str (default: 'MMD_AT_PLUS_A')] (Has effect only with `sparse = True`, `lstsq = False`, `sym_pos = True`, and no SuiteSparse.) A matrix is factorized in each iteration of the algorithm. This option specifies how to permute the columns of the matrix for sparsity preservation. Acceptable values are:
- `NATURAL`: natural ordering.
- `MMD_ATA`: minimum degree ordering on the structure of A^T A.
- `MMD_AT_PLUS_A`: minimum degree ordering on the structure of A^T+A.
- `COLAMD`: approximate minimum degree column ordering.

This option can impact the convergence of the interior point algorithm; test different values to determine which performs best for your problem. For more information, refer to `scipy.sparse.linalg.splu`.

unknown_options
[dict] Optional arguments not used by this particular solver. If *unknown_options* is non-empty a warning is issued listing all unused options.

Notes

This method implements the algorithm outlined in [4] with ideas from [8] and a structure inspired by the simpler methods of [6].

The primal-dual path following method begins with initial 'guesses' of the primal and dual variables of the standard form problem and iteratively attempts to solve the (nonlinear) Karush-Kuhn-Tucker conditions for the problem with a gradually reduced logarithmic barrier term added to the objective. This particular implementation uses a homogeneous self-dual formulation, which provides certificates of infeasibility or unboundedness where applicable.

The default initial point for the primal and dual variables is that defined in [4] Section 4.4 Equation 8.22. Optionally (by setting initial point option `ip=True`), an alternate (potentially improved) starting point can be calculated according to the additional recommendations of [4] Section 4.4.

A search direction is calculated using the predictor-corrector method (single correction) proposed by Mehrota and detailed in [4] Section 4.1. (A potential improvement would be to implement the method of multiple corrections described in [4] Section 4.2.) In practice, this is accomplished by solving the normal equations, [4] Section 5.1 Equations 8.31 and 8.32, derived from the Newton equations [4] Section 5 Equations 8.25 (compare to [4] Section 4 Equations 8.6-8.8). The advantage of solving the normal equations rather than 8.25 directly is that the matrices involved are symmetric positive definite, so Cholesky decomposition can be used rather than the more expensive LU factorization.

With default options, the solver used to perform the factorization depends on third-party software availability and the conditioning of the problem.

For dense problems, solvers are tried in the following order:

1. `scipy.linalg.cho_factor`
2. `scipy.linalg.solve` with option `sym_pos=True`
3. `scipy.linalg.solve` with option `sym_pos=False`
4. `scipy.linalg.lstsq`

For sparse problems:

1. `sksparse.cholmod.cholesky` (if scikit-sparse and SuiteSparse are installed)

2. `scipy.sparse.linalg.factorized` (if scikit-umfpack and SuiteSparse are installed)
3. `scipy.sparse.linalg.splu` (which uses SuperLU distributed with SciPy)
4. `scipy.sparse.linalg.lsqr`

If the solver fails for any reason, successively more robust (but slower) solvers are attempted in the order indicated. Attempting, failing, and re-starting factorization can be time consuming, so if the problem is numerically challenging, options can be set to bypass solvers that are failing. Setting `cholesky=False` skips to solver 2, `sym_pos=False` skips to solver 3, and `lstsq=True` skips to solver 4 for both sparse and dense problems.

Potential improvements for combatting issues associated with dense columns in otherwise sparse problems are outlined in [4] Section 5.3 and [10] Section 4.1-4.2; the latter also discusses the alleviation of accuracy issues associated with the substitution approach to free variables.

After calculating the search direction, the maximum possible step size that does not activate the non-negativity constraints is calculated, and the smaller of this step size and unity is applied (as in [4] Section 4.1.) [4] Section 4.3 suggests improvements for choosing the step size.

The new point is tested according to the termination conditions of [4] Section 4.5. The same tolerance, which can be set using the `tol` option, is used for all checks. (A potential improvement would be to expose the different tolerances to be set independently.) If optimality, unboundedness, or infeasibility is detected, the solve procedure terminates; otherwise it repeats.

Whereas the top level `linprog` module expects a problem of form:

Minimize:

```
c @ x
```

Subject to:

```
A_ub @ x <= b_ub
A_eq @ x == b_eq
 lb <= x <= ub
```

where `lb = 0` and `ub = None` unless set in `bounds`. The problem is automatically converted to the form:

Minimize:

```
c @ x
```

Subject to:

```
A @ x == b
    x >= 0
```

for solution. That is, the original problem contains equality, upper-bound and variable constraints whereas the method specific solver requires equality constraints and variable non-negativity. `linprog` converts the original problem to standard form by converting the simple bounds to upper bound constraints, introducing non-negative slack variables for inequality constraints, and expressing unbounded variables as the difference between two non-negative variables. The problem is converted back to the original form before results are reported.

linprog(method='revised simplex')

scipy.optimize.**linprog**(*c*, *A_ub=None*, *b_ub=None*, *A_eq=None*, *b_eq=None*, *bounds=None*, *method='revised_simplex'*, *callback=None*, *options={'maxiter': 5000, 'disp': False, 'presolve': True, 'tol': 1e-12, 'autoscale': False, 'rr': True, 'maxupdate': 10, 'mast': False, 'pivot': 'mrc'}*, *x0=None*)

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using the revised simplex method.

Linear programming solves problems of the following form:

$$\begin{aligned} \min_x \ & c^T x \\ \text{such that } & A_{ub} x \leq b_{ub}, \\ & A_{eq} x = b_{eq}, \\ & l \leq x \leq u, \end{aligned}$$

where x is a vector of decision variables; c, b_{ub}, b_{eq}, l, and u are vectors; and A_{ub} and A_{eq} are matrices.

Alternatively, that's:

minimize:

```
c @ x
```

such that:

```
A_ub @ x <= b_ub
A_eq @ x == b_eq
lb <= x <= ub
```

Note that by default `lb = 0` and `ub = None` unless specified with `bounds`.

Parameters

c [1-D array] The coefficients of the linear objective function to be minimized.

A_ub [2-D array, optional] The inequality constraint matrix. Each row of `A_ub` specifies the coefficients of a linear inequality constraint on `x`.

b_ub [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of `A_ub @ x`.

A_eq [2-D array, optional] The equality constraint matrix. Each row of `A_eq` specifies the coefficients of a linear equality constraint on `x`.

b_eq [1-D array, optional] The equality constraint vector. Each element of `A_eq @ x` must equal the corresponding element of `b_eq`.

bounds [sequence, optional] A sequence of `(min, max)` pairs for each element in `x`, defining the minimum and maximum values of that decision variable. Use `None` to indicate that there is no bound. By default, bounds are `(0, None)` (all decision variables are non-negative). If a single tuple `(min, max)` is provided, then `min` and `max` will serve as bounds for all decision variables.

method [str] This is the method-specific documentation for 'revised simplex'. *'highs'*, *'highs-ds'*, *'highs-ipm'*, *'interior-point'* (default), and *'simplex'* (legacy) are also available.

callback [callable, optional] Callback function to be executed once per iteration.

x0 [1-D array, optional] Guess values of the decision variables, which will be refined by the optimization algorithm. This argument is currently used only by the 'revised simplex' method, and can only be used if *x0* represents a basic feasible solution.

Returns

res [OptimizeResult] A *scipy.optimize.OptimizeResult* consisting of the fields:

- **x** [1-D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
- **fun** [float] The optimal value of the objective function `c @ x`.
- **slack** [1-D array] The (nominally positive) values of the slack variables, `b_ub - A_ub @ x`.
- **con** [1-D array] The (nominally zero) residuals of the equality constraints, `b_eq - A_eq @ x`.
- **success** [bool] `True` when the algorithm succeeds in finding an optimal solution.
- **status** [int] An integer representing the exit status of the algorithm.
  - `0` : Optimization terminated successfully.
  - `1` : Iteration limit reached.
  - `2` : Problem appears to be infeasible.
  - `3` : Problem appears to be unbounded.
  - `4` : Numerical difficulties encountered.
  - `5` : Problem has no constraints; turn presolve on.
  - `6` : Invalid guess provided.
- **message** [str] A string descriptor of the exit status of the algorithm.
- **nit** [int] The total number of iterations performed in all phases.

See also:

For documentation for the rest of the parameters, see *scipy.optimize.linprog*

Options

maxiter [int (default: 5000)] The maximum number of iterations to perform in either phase.

disp [bool (default: False)] Set to `True` if indicators of optimization status are to be printed to the console each iteration.

presolve [bool (default: True)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting `True`; set to `False` if presolve is to be disabled.

tol [float (default: 1e-12)] The tolerance which determines when a solution is "close enough" to zero in Phase 1 to be considered a basic feasible solution or close enough to positive to serve as an optimal solution.

autoscale [bool (default: False)] Set to `True` to automatically perform equilibration. Consider using this option if the numerical values in the constraints are separated by several orders of magnitude.

rr [bool (default: True)] Set to `False` to disable automatic redundancy removal.

maxupdate [int (default: 10)] The maximum number of updates performed on the LU factorization. After this many updates is reached, the basis matrix is factorized from scratch.

mast [bool (default: False)] Minimize Amortized Solve Time. If enabled, the average time to solve a linear system using the basis factorization is measured. Typically, the average solve time will decrease with each successive solve after initial factorization, as factorization takes much more time than the solve operation (and updates). Eventually, however, the updated factorization becomes sufficiently complex that the average solve time begins to increase. When this is detected, the basis is refactorized from scratch. Enable this option to maximize speed at the risk of nondeterministic behavior. Ignored if `maxupdate` is 0.

pivot ["mrc" or "bland" (default: "mrc")] Pivot rule: Minimum Reduced Cost ("mrc") or Bland's rule ("bland"). Choose Bland's rule if iteration limit is reached and cycling is suspected.

unknown_options
[dict] Optional arguments not used by this particular solver. If *unknown_options* is non-empty a warning is issued listing all unused options.

Notes

Method *revised simplex* uses the revised simplex method as described in [9], except that a factorization [11] of the basis matrix, rather than its inverse, is efficiently maintained and used to solve the linear systems at each iteration of the algorithm.

linprog(method='highs-ipm')

`scipy.optimize.linprog`(*c*, *A_ub=None*, *b_ub=None*, *A_eq=None*, *b_eq=None*, *bounds=None*, *method='highs-ipm'*, *callback=None*, *options={'maxiter': None, 'disp': False, 'presolve': True, 'time_limit': None, 'dual_feasibility_tolerance': None, 'primal_feasibility_tolerance': None, 'ipm_optimality_tolerance': None}*, *x0=None*)

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using the HiGHS interior point solver.

Linear programming solves problems of the following form:

$$\begin{aligned} \min_x \ & c^T x \\ \text{such that } & A_{ub} x \leq b_{ub}, \\ & A_{eq} x = b_{eq}, \\ & l \leq x \leq u, \end{aligned}$$

where x is a vector of decision variables; c, b_{ub}, b_{eq}, l, and u are vectors; and A_{ub} and A_{eq} are matrices.

Alternatively, that's:

minimize:

```
c @ x
```

such that:

```
A_ub @ x <= b_ub
A_eq @ x == b_eq
lb <= x <= ub
```

Note that by default `lb = 0` and `ub = None` unless specified with `bounds`.

Parameters

c [1-D array] The coefficients of the linear objective function to be minimized.

A_ub [2-D array, optional] The inequality constraint matrix. Each row of `A_ub` specifies the coefficients of a linear inequality constraint on `x`.

b_ub [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of `A_ub @ x`.

A_eq [2-D array, optional] The equality constraint matrix. Each row of `A_eq` specifies the coefficients of a linear equality constraint on `x`.

b_eq [1-D array, optional] The equality constraint vector. Each element of `A_eq @ x` must equal the corresponding element of `b_eq`.

bounds [sequence, optional] A sequence of `(min, max)` pairs for each element in `x`, defining the minimum and maximum values of that decision variable. Use `None` to indicate that there is no bound. By default, bounds are `(0, None)` (all decision variables are non-negative). If a single tuple `(min, max)` is provided, then `min` and `max` will serve as bounds for all decision variables.

method [str] This is the method-specific documentation for 'highs-ipm'. *'highs-ipm'*, *'highs-ds'*, *'interior-point'* (default), *'revised simplex'*, and *'simplex'* (legacy) are also available.

Returns

res [OptimizeResult] A *scipy.optimize.OptimizeResult* consisting of the fields:

- **x** [1D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
- **fun** [float] The optimal value of the objective function `c @ x`.
- **slack** [1D array] The (nominally positive) values of the slack, `b_ub - A_ub @ x`.
- **con** [1D array] The (nominally zero) residuals of the equality constraints, `b_eq - A_eq @ x`.
- **success** [bool] `True` when the algorithm succeeds in finding an optimal solution.
- **status** [int] An integer representing the exit status of the algorithm.
  `0` : Optimization terminated successfully.
  `1` : Iteration or time limit reached.
  `2` : Problem appears to be infeasible.
  `3` : Problem appears to be unbounded.
  `4` : The HiGHS solver ran into a problem.
- **message** [str] A string descriptor of the exit status of the algorithm.
- **nit** [int] The total number of iterations performed. For the HiGHS interior-point method, this does not include crossover iterations.
- **crossover_nit** [int] The number of primal/dual pushes performed during the crossover routine for the HiGHS interior-point method.
- **ineqlin** [OptimizeResult] Solution and sensitivity information corresponding to the inequality constraints, *b_ub*. A dictionary consisting of the fields:
  - **residual** [np.ndnarray] The (nominally positive) values of the slack variables, `b_ub - A_ub @ x`. This quantity is also commonly referred to as "slack".
  - **marginals** [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the right-hand side of the inequality constraints, *b_ub*.
- **eqlin** [OptimizeResult] Solution and sensitivity information corresponding to the equality constraints, *b_eq*. A dictionary consisting of the fields:
  - **residual** [np.ndarray] The (nominally zero) residuals of the equality constraints, `b_eq - A_eq @ x`.
  - **marginals** [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the right-hand side of the equality constraints, *b_eq*.
- **lower, upper** [OptimizeResult] Solution and sensitivity information corresponding to the lower and upper bounds on decision variables, *bounds*.
  - **residual** [np.ndarray] The (nominally positive) values of the quantity `x - lb` (lower) or `ub - x` (upper).

marginals [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the lower and upper *bounds*.

See also:

For documentation for the rest of the parameters, see *scipy.optimize.linprog*

Options

maxiter [int] The maximum number of iterations to perform in either phase. For *'highs-ipm'*, this does not include the number of crossover iterations. Default is the largest possible value for an `int` on the platform.

disp [bool (default: `False`)] Set to `True` if indicators of optimization status are to be printed to the console during optimization.

presolve [bool (default: `True`)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting `True`; set to `False` if presolve is to be disabled.

time_limit [float] The maximum time in seconds allotted to solve the problem; default is the largest possible value for a `double` on the platform.

dual_feasibility_tolerance
[double (default: 1e-07)] The minimum of this and `primal_feasibility_tolerance` is used for the feasibility tolerance of *'highs-ipm'*.

primal_feasibility_tolerance
[double (default: 1e-07)] The minimum of this and `dual_feasibility_tolerance` is used for the feasibility tolerance of *'highs-ipm'*.

ipm_optimality_tolerance
[double (default: `1e-08`)] Optimality tolerance for *'highs-ipm'*. Minimum allowable value is 1e-12.

unknown_options
[dict] Optional arguments not used by this particular solver. If `unknown_options` is non-empty, a warning is issued listing all unused options.

Notes

Method *'highs-ipm'* is a wrapper of a C++ implementation of an **i**nterior-**p**oint **m**ethod [13]; it features a crossover routine, so it is as accurate as a simplex solver. Method *'highs-ds'* is a wrapper of the C++ high performance dual revised simplex implementation (HSOL) [13], [14]. Method *'highs'* chooses between the two automatically. For new code involving *linprog*, we recommend explicitly choosing one of these three method values instead of *'interior-point'* (default), *'revised simplex'*, and *'simplex'* (legacy).

The result fields *ineqlin*, *eqlin*, *lower*, and *upper* all contain *marginals*, or partial derivatives of the objective function with respect to the right-hand side of each constraint. These partial derivatives are also referred to as "Lagrange multipliers", "dual values", and "shadow prices". The sign convention of *marginals* is opposite that of Lagrange multipliers produced by many nonlinear solvers.

linprog(method='highs-ds')

scipy.optimize.**linprog**(*c*, *A_ub=None*, *b_ub=None*, *A_eq=None*, *b_eq=None*, *bounds=None*, *method='highs-ds'*, *callback=None*, *options={'maxiter': None, 'disp': False, 'presolve': True, 'time_limit': None, 'dual_feasibility_tolerance': None, 'primal_feasibility_tolerance': None, 'simplex_dual_edge_weight_strategy': None}*, *x0=None*)

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using the HiGHS dual simplex solver.

Linear programming solves problems of the following form:

$$\begin{aligned} \min_x \ & c^T x \\ \text{such that } & A_{ub} x \leq b_{ub}, \\ & A_{eq} x = b_{eq}, \\ & l \leq x \leq u, \end{aligned}$$

where x is a vector of decision variables; c, b_{ub}, b_{eq}, l, and u are vectors; and A_{ub} and A_{eq} are matrices.

Alternatively, that's:

minimize:

```
c @ x
```

such that:

```
A_ub @ x <= b_ub
A_eq @ x == b_eq
lb <= x <= ub
```

Note that by default `lb = 0` and `ub = None` unless specified with `bounds`.

Parameters

c [1-D array] The coefficients of the linear objective function to be minimized.

A_ub [2-D array, optional] The inequality constraint matrix. Each row of `A_ub` specifies the coefficients of a linear inequality constraint on `x`.

b_ub [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of `A_ub @ x`.

A_eq [2-D array, optional] The equality constraint matrix. Each row of `A_eq` specifies the coefficients of a linear equality constraint on `x`.

b_eq [1-D array, optional] The equality constraint vector. Each element of `A_eq @ x` must equal the corresponding element of `b_eq`.

bounds [sequence, optional] A sequence of `(min, max)` pairs for each element in `x`, defining the minimum and maximum values of that decision variable. Use `None` to indicate that there is no bound. By default, bounds are `(0, None)` (all decision variables are non-negative). If a single tuple `(min, max)` is provided, then `min` and `max` will serve as bounds for all decision variables.

method [str] This is the method-specific documentation for 'highs-ds'. *'highs'*, *'highs-ipm'*, *'interior-point'* (default), *'revised simplex'*, and *'simplex'* (legacy) are also available.

Returns

res [OptimizeResult] A *scipy.optimize.OptimizeResult* consisting of the fields:

- **x** [1D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
- **fun** [float] The optimal value of the objective function `c @ x`.
- **slack** [1D array] The (nominally positive) values of the slack, `b_ub - A_ub @ x`.
- **con** [1D array] The (nominally zero) residuals of the equality constraints, `b_eq - A_eq @ x`.
- **success** [bool] `True` when the algorithm succeeds in finding an optimal solution.
- **status** [int] An integer representing the exit status of the algorithm.
  `0` : Optimization terminated successfully.
  `1` : Iteration or time limit reached.
  `2` : Problem appears to be infeasible.
  `3` : Problem appears to be unbounded.
  `4` : The HiGHS solver ran into a problem.
- **message** [str] A string descriptor of the exit status of the algorithm.
- **nit** [int] The total number of iterations performed. This includes iterations in all phases.
- **crossover_nit** [int] This is always `0` for the HiGHS simplex method. For the HiGHS interior-point method, this is the number of primal/dual pushes performed during the crossover routine.
- **ineqlin** [OptimizeResult] Solution and sensitivity information corresponding to the inequality constraints, *b_ub*. A dictionary consisting of the fields:
  - **residual** [np.ndnarray] The (nominally positive) values of the slack variables, `b_ub - A_ub @ x`. This quantity is also commonly referred to as "slack".
  - **marginals** [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the right-hand side of the inequality constraints, *b_ub*.
- **eqlin** [OptimizeResult] Solution and sensitivity information corresponding to the equality constraints, *b_eq*. A dictionary consisting of the fields:
  - **residual** [np.ndarray] The (nominally zero) residuals of the equality constraints, `b_eq - A_eq @ x`.
  - **marginals** [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the right-hand side of the equality constraints, *b_eq*.
- **lower, upper** [OptimizeResult] Solution and sensitivity information corresponding to the lower and upper bounds on decision variables, *bounds*.
  - **residual** [np.ndarray] The (nominally positive) values of the quantity `x - lb` (lower) or `ub - x` (upper).
  - **marginals** [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the lower and upper *bounds*.

See also:

For documentation for the rest of the parameters, see *scipy.optimize.linprog*

Options

- **maxiter** [int] The maximum number of iterations to perform in either phase. Default is the largest possible value for an `int` on the platform.
- **disp** [bool (default: `False`)] Set to `True` if indicators of optimization status are to be printed to the console during optimization.

presolve [bool (default: `True`)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting `True`; set to `False` if presolve is to be disabled.

time_limit [float] The maximum time in seconds allotted to solve the problem; default is the largest possible value for a `double` on the platform.

dual_feasibility_tolerance
[double (default: 1e-07)] Dual feasibility tolerance for *'highs-ds'*.

primal_feasibility_tolerance
[double (default: 1e-07)] Primal feasibility tolerance for *'highs-ds'*.

simplex_dual_edge_weight_strategy
[str (default: None)] Strategy for simplex dual edge weights. The default, `None`, automatically selects one of the following.
`'dantzig'` uses Dantzig's original strategy of choosing the most negative reduced cost.
`'devex'` uses the strategy described in [15].
`steepest` uses the exact steepest edge strategy as described in [16].
`'steepest-devex'` begins with the exact steepest edge strategy until the computation is too costly or inexact and then switches to the devex method.
Curently, `None` always selects `'steepest-devex'`, but this may change as new options become available.

unknown_options
[dict] Optional arguments not used by this particular solver. If `unknown_options` is non-empty, a warning is issued listing all unused options.

Notes

Method *'highs-ds'* is a wrapper of the C++ high performance dual revised simplex implementation (HSOL) [13], [14]. Method *'highs-ipm'* is a wrapper of a C++ implementation of an **i**nterior-**p**oint **m**ethod [13]; it features a crossover routine, so it is as accurate as a simplex solver. Method *'highs'* chooses between the two automatically. For new code involving *linprog*, we recommend explicitly choosing one of these three method values instead of *'interior-point'* (default), *'revised simplex'*, and *'simplex'* (legacy).

The result fields *ineqlin*, *eqlin*, *lower*, and *upper* all contain *marginals*, or partial derivatives of the objective function with respect to the right-hand side of each constraint. These partial derivatives are also referred to as "Lagrange multipliers", "dual values", and "shadow prices". The sign convention of *marginals* is opposite that of Lagrange multipliers produced by many nonlinear solvers.

[13], [14], [15], [16]

linprog(method='highs')

`scipy.optimize.`**`linprog`**(*c*, *A_ub=None*, *b_ub=None*, *A_eq=None*, *b_eq=None*, *bounds=None*, *method='highs'*, *callback=None*, *options={'maxiter': None, 'disp': False, 'presolve': True, 'time_limit': None, 'dual_feasibility_tolerance': None, 'primal_feasibility_tolerance': None, 'ipm_optimality_tolerance': None, 'simplex_dual_edge_weight_strategy': None}*, *x0=None*)

Linear programming: minimize a linear objective function subject to linear equality and inequality constraints using one of the HiGHS solvers.

Linear programming solves problems of the following form:

$$\min_x c^T x$$
$$\text{such that } A_{ub} x \leq b_{ub},$$
$$A_{eq} x = b_{eq},$$
$$l \leq x \leq u,$$

where x is a vector of decision variables; c, b_{ub}, b_{eq}, l, and u are vectors; and A_{ub} and A_{eq} are matrices.

Alternatively, that's:

minimize:

```
c @ x
```

such that:

```
A_ub @ x <= b_ub
A_eq @ x == b_eq
lb <= x <= ub
```

Note that by default `lb = 0` and `ub = None` unless specified with `bounds`.

Parameters

c [1-D array] The coefficients of the linear objective function to be minimized.

A_ub [2-D array, optional] The inequality constraint matrix. Each row of `A_ub` specifies the coefficients of a linear inequality constraint on `x`.

b_ub [1-D array, optional] The inequality constraint vector. Each element represents an upper bound on the corresponding value of `A_ub @ x`.

A_eq [2-D array, optional] The equality constraint matrix. Each row of `A_eq` specifies the coefficients of a linear equality constraint on `x`.

b_eq [1-D array, optional] The equality constraint vector. Each element of `A_eq @ x` must equal the corresponding element of `b_eq`.

bounds [sequence, optional] A sequence of `(min, max)` pairs for each element in `x`, defining the minimum and maximum values of that decision variable. Use `None` to indicate that there is no bound. By default, bounds are `(0, None)` (all decision variables are non-negative). If a single tuple `(min, max)` is provided, then `min` and `max` will serve as bounds for all decision variables.

method [str] This is the method-specific documentation for 'highs', which chooses automatically between *'highs-ds'* and *'highs-ipm'*. *'interior-point'* (default), *'revised simplex'*, and *'simplex'* (legacy) are also available.

Returns

res [OptimizeResult] A *`scipy.optimize.OptimizeResult`* consisting of the fields:

- **x** [1D array] The values of the decision variables that minimizes the objective function while satisfying the constraints.
- **fun** [float] The optimal value of the objective function `c @ x`.
- **slack** [1D array] The (nominally positive) values of the slack, `b_ub - A_ub @ x`.
- **con** [1D array] The (nominally zero) residuals of the equality constraints, `b_eq - A_eq @ x`.
- **success** [bool] `True` when the algorithm succeeds in finding an optimal solution.
- **status** [int] An integer representing the exit status of the algorithm.
  `0` : Optimization terminated successfully.
  `1` : Iteration or time limit reached.
  `2` : Problem appears to be infeasible.

`3` : Problem appears to be unbounded.
`4` : The HiGHS solver ran into a problem.

message [str] A string descriptor of the exit status of the algorithm.

nit [int] The total number of iterations performed. For the HiGHS simplex method, this includes iterations in all phases. For the HiGHS interior-point method, this does not include crossover iterations.

crossover_nit
[int] The number of primal/dual pushes performed during the crossover routine for the HiGHS interior-point method. This is `0` for the HiGHS simplex method.

ineqlin [OptimizeResult] Solution and sensitivity information corresponding to the inequality constraints, *b_ub*. A dictionary consisting of the fields:

- **residual** [np.ndnarray] The (nominally positive) values of the slack variables, `b_ub - A_ub @ x`. This quantity is also commonly referred to as "slack".
- **marginals** [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the right-hand side of the inequality constraints, *b_ub*.

eqlin [OptimizeResult] Solution and sensitivity information corresponding to the equality constraints, *b_eq*. A dictionary consisting of the fields:

- **residual** [np.ndarray] The (nominally zero) residuals of the equality constraints, `b_eq - A_eq @ x`.
- **marginals** [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the right-hand side of the equality constraints, *b_eq*.

lower, upper
[OptimizeResult] Solution and sensitivity information corresponding to the lower and upper bounds on decision variables, *bounds*.

- **residual** [np.ndarray] The (nominally positive) values of the quantity `x - lb` (lower) or `ub - x` (upper).
- **marginals** [np.ndarray] The sensitivity (partial derivative) of the objective function with respect to the lower and upper *bounds*.

See also:

For documentation for the rest of the parameters, see *scipy.optimize.linprog*

Options

maxiter [int] The maximum number of iterations to perform in either phase. For *'highs-ipm'*, this does not include the number of crossover iterations. Default is the largest possible value for an `int` on the platform.

disp [bool (default: `False`)] Set to `True` if indicators of optimization status are to be printed to the console during optimization.

presolve [bool (default: `True`)] Presolve attempts to identify trivial infeasibilities, identify trivial unboundedness, and simplify the problem before sending it to the main solver. It is generally recommended to keep the default setting `True`; set to `False` if presolve is to be disabled.

time_limit [float] The maximum time in seconds allotted to solve the problem; default is the largest possible value for a `double` on the platform.

dual_feasibility_tolerance
[double (default: 1e-07)] Dual feasibility tolerance for *'highs-ds'*. The minimum of this and `primal_feasibility_tolerance` is used for the feasibility tolerance of *'highs-ipm'*.

primal_feasibility_tolerance
[double (default: 1e-07)] Primal feasibility tolerance for *'highs-ds'*. The minimum of this and `dual_feasibility_tolerance` is used for the feasibility tolerance of *'highs-ipm'*.

ipm_optimality_tolerance
: [double (default: `1e-08`)] Optimality tolerance for *'highs-ipm'*. Minimum allowable value is 1e-12.

simplex_dual_edge_weight_strategy
: [str (default: None)] Strategy for simplex dual edge weights. The default, `None`, automatically selects one of the following.
`'dantzig'` uses Dantzig's original strategy of choosing the most negative reduced cost.
`'devex'` uses the strategy described in [15].
`steepest` uses the exact steepest edge strategy as described in [16].
`'steepest-devex'` begins with the exact steepest edge strategy until the computation is too costly or inexact and then switches to the devex method.
Curently, `None` always selects `'steepest-devex'`, but this may change as new options become available.

unknown_options
: [dict] Optional arguments not used by this particular solver. If `unknown_options` is non-empty, a warning is issued listing all unused options.

Notes

Method *'highs-ds'* is a wrapper of the C++ high performance dual revised simplex implementation (HSOL) [13], [14]. Method *'highs-ipm'* is a wrapper of a C++ implementation of an **i**nterior-**p**oint **m**ethod [13]; it features a crossover routine, so it is as accurate as a simplex solver. Method *'highs'* chooses between the two automatically. For new code involving *linprog*, we recommend explicitly choosing one of these three method values instead of *'interior-point'* (default), *'revised simplex'*, and *'simplex'* (legacy).

The result fields *ineqlin*, *eqlin*, *lower*, and *upper* all contain *marginals*, or partial derivatives of the objective function with respect to the right-hand side of each constraint. These partial derivatives are also referred to as "Lagrange multipliers", "dual values", and "shadow prices". The sign convention of *marginals* is opposite that of Lagrange multipliers produced by many nonlinear solvers.

[13], [14], [15], [16]

The simplex, interior-point, and revised simplex methods support callback functions, such as:

linprog_verbose_callback(res)	A sample callback function demonstrating the linprog callback interface.

scipy.optimize.linprog_verbose_callback

scipy.optimize.**linprog_verbose_callback**(*res*)
: A sample callback function demonstrating the linprog callback interface. This callback produces detailed output to sys.stdout before each iteration and after the final iteration of the simplex algorithm.

Parameters

res
: [A *scipy.optimize.OptimizeResult* consisting of the following fields:]

x
: [1-D array] The independent variable vector which optimizes the linear programming problem.

fun
: [float] Value of the objective function.

success
: [bool] True if the algorithm succeeded in finding an optimal solution.

slack
: [1-D array] The values of the slack variables. Each slack variable corresponds to an inequality constraint. If the slack is zero, then the corresponding constraint

is active.

con [1-D array] The (nominally zero) residuals of the equality constraints, that is, `b - A_eq @ x`

phase [int] The phase of the optimization being executed. In phase 1 a basic feasible solution is sought and the T has an additional row representing an alternate objective function.

status [int] An integer representing the exit status of the optimization:

```
0 : Optimization terminated successfully
1 : Iteration limit reached
2 : Problem appears to be infeasible
3 : Problem appears to be unbounded
4 : Serious numerical difficulties encountered
```

nit [int] The number of iterations performed.

message [str] A string descriptor of the exit status of the optimization.

Assignment problems

linear_sum_assignment(cost_matrix[, maximize])	Solve the linear sum assignment problem.
quadratic_assignment(A, B[, method, options])	Approximates solution to the quadratic assignment problem and the graph matching problem.

scipy.optimize.linear_sum_assignment

scipy.optimize.**linear_sum_assignment**(*cost_matrix*, *maximize=False*)

Solve the linear sum assignment problem.

Parameters

cost_matrix
[array] The cost matrix of the bipartite graph.

maximize [bool (default: False)] Calculates a maximum weight matching if true.

Returns

row_ind, col_ind
[array] An array of row indices and one of corresponding column indices giving the optimal assignment. The cost of the assignment can be computed as `cost_matrix[row_ind, col_ind].sum()`. The row indices will be sorted; in the case of a square cost matrix they will be equal to `numpy.arange(cost_matrix.shape[0])`.

See also:

scipy.sparse.csgraph.min_weight_full_bipartite_matching

for sparse inputs

Notes

The linear sum assignment problem [1] is also known as minimum weight matching in bipartite graphs. A problem instance is described by a matrix C, where each C[i,j] is the cost of matching vertex i of the first partite set (a "worker") and vertex j of the second set (a "job"). The goal is to find a complete assignment of workers to jobs of minimal cost.

Formally, let X be a boolean matrix where $X[i,j] = 1$ iff row i is assigned to column j. Then the optimal assignment has cost

$$\min \sum_i \sum_j C_{i,j} X_{i,j}$$

where, in the case where the matrix X is square, each row is assigned to exactly one column, and each column to exactly one row.

This function can also solve a generalization of the classic assignment problem where the cost matrix is rectangular. If it has more rows than columns, then not every row needs to be assigned to a column, and vice versa.

This implementation is a modified Jonker-Volgenant algorithm with no initialization, described in ref. [2].

New in version 0.17.0.

Examples

```
>>> cost = np.array([[4, 1, 3], [2, 0, 5], [3, 2, 2]])
>>> from scipy.optimize import linear_sum_assignment
>>> row_ind, col_ind = linear_sum_assignment(cost)
>>> col_ind
array([1, 0, 2])
>>> cost[row_ind, col_ind].sum()
5
```

scipy.optimize.quadratic_assignment

scipy.optimize.**quadratic_assignment**(*A*, *B*, *method='faq'*, *options=None*)

Approximates solution to the quadratic assignment problem and the graph matching problem.

Quadratic assignment solves problems of the following form:

$$\min_P \ \text{trace}(A^T P B P^T)$$
$$\text{s.t. } P \in \mathcal{P}$$

where $\mathcal{P}$ is the set of all permutation matrices, and A and B are square matrices.

Graph matching tries to *maximize* the same objective function. This algorithm can be thought of as finding the alignment of the nodes of two graphs that minimizes the number of induced edge disagreements, or, in the case of weighted graphs, the sum of squared edge weight differences.

Note that the quadratic assignment problem is NP-hard. The results given here are approximations and are not guaranteed to be optimal.

Parameters

A [2-D array, square] The square matrix A in the objective function above.
B [2-D array, square] The square matrix B in the objective function above.
method [str in {'faq', '2opt'} (default: 'faq')] The algorithm used to solve the problem. *'faq'* (default) and *'2opt'* are available.
options [dict, optional] A dictionary of solver options. All solvers support the following:
maximize [bool (default: False)] Maximizes the objective function if `True`.
partial_match
[2-D array of integers, optional (default: None)] Fixes part of the matching. Also known as a "seed" [2].
Each row of *partial_match* specifies a pair of matched nodes: node `partial_match[i, 0]` of *A* is matched to node `partial_match[i, 1]` of *B*. The array has shape `(m, 2)`, where `m` is not greater than the number of nodes, n.
rng [{None, int, `numpy.random.Generator`,]
`numpy.random.RandomState`}, optional
If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.
For method-specific options, see *`show_options('quadratic_assignment')`*.

Returns

res [OptimizeResult] *`OptimizeResult`* containing the following fields.
col_ind [1-D array] Column indices corresponding to the best permutation found of the nodes of *B*.
fun [float] The objective value of the solution.
nit [int] The number of iterations performed during optimization.

Notes

The default method *'faq'* uses the Fast Approximate QAP algorithm [1]; it typically offers the best combination of speed and accuracy. Method *'2opt'* can be computationally expensive, but may be a useful alternative, or it can be used to refine the solution returned by another method.

References

[1], [2], [3]

Examples

```
>>> from scipy.optimize import quadratic_assignment
>>> A = np.array([[0, 80, 150, 170], [80, 0, 130, 100],
...               [150, 130, 0, 120], [170, 100, 120, 0]])
>>> B = np.array([[0, 5, 2, 7], [0, 0, 3, 8],
...               [0, 0, 0, 3], [0, 0, 0, 0]])
>>> res = quadratic_assignment(A, B)
>>> print(res)
 col_ind: array([0, 3, 2, 1])
     fun: 3260
     nit: 9
```

The see the relationship between the returned `col_ind` and `fun`, use `col_ind` to form the best permutation matrix found, then evaluate the objective function $f(P) = trace(A^T P B P^T)$.

```
>>> perm = res['col_ind']
>>> P = np.eye(len(A), dtype=int)[perm]
>>> fun = np.trace(A.T @ P @ B @ P.T)
>>> print(fun)
3260
```

Alternatively, to avoid constructing the permutation matrix explicitly, directly permute the rows and columns of the distance matrix.

```
>>> fun = np.trace(A.T @ B[perm][:, perm])
>>> print(fun)
3260
```

Although not guaranteed in general, `quadratic_assignment` happens to have found the globally optimal solution.

```
>>> from itertools import permutations
>>> perm_opt, fun_opt = None, np.inf
>>> for perm in permutations([0, 1, 2, 3]):
...     perm = np.array(perm)
...     fun = np.trace(A.T @ B[perm][:, perm])
...     if fun < fun_opt:
...         fun_opt, perm_opt = fun, perm
>>> print(np.array_equal(perm_opt, res['col_ind']))
True
```

Here is an example for which the default method, *'faq'*, does not find the global optimum.

```
>>> A = np.array([[0, 5, 8, 6], [5, 0, 5, 1],
...               [8, 5, 0, 2], [6, 1, 2, 0]])
>>> B = np.array([[0, 1, 8, 4], [1, 0, 5, 2],
...               [8, 5, 0, 5], [4, 2, 5, 0]])
>>> res = quadratic_assignment(A, B)
>>> print(res)
 col_ind: array([1, 0, 3, 2])
     fun: 178
     nit: 13
```

If accuracy is important, consider using *'2opt'* to refine the solution.

```
>>> guess = np.array([np.arange(len(A)), res.col_ind]).T
>>> res = quadratic_assignment(A, B, method="2opt",
...                            options = {'partial_guess': guess})
>>> print(res)
 col_ind: array([1, 2, 3, 0])
     fun: 176
     nit: 17
```

The *quadratic_assignment* function supports the following methods:

quadratic_assignment(method='faq')

scipy.optimize.**quadratic_assignment**(*A*, *B*, *method='faq'*, *options={'maximize': False, 'partial_match': None, 'rng': None, 'P0': 'barycenter', 'shuffle_input': False, 'maxiter': 30, 'tol': 0.03}*)

Solve the quadratic assignment problem (approximately).

This function solves the Quadratic Assignment Problem (QAP) and the Graph Matching Problem (GMP) using the Fast Approximate QAP Algorithm (FAQ) [1].

Quadratic assignment solves problems of the following form:

$$\min_P \ \text{trace}(A^T P B P^T)$$
$$\text{s.t. } P \in \mathcal{P}$$

where $\mathcal{P}$ is the set of all permutation matrices, and A and B are square matrices.

Graph matching tries to *maximize* the same objective function. This algorithm can be thought of as finding the alignment of the nodes of two graphs that minimizes the number of induced edge disagreements, or, in the case of weighted graphs, the sum of squared edge weight differences.

Note that the quadratic assignment problem is NP-hard. The results given here are approximations and are not guaranteed to be optimal.

Parameters

A [2-D array, square] The square matrix A in the objective function above.

B [2-D array, square] The square matrix B in the objective function above.

method [str in {'faq', '2opt'} (default: 'faq')] The algorithm used to solve the problem. This is the method-specific documentation for 'faq'. *'2opt'* is also available.

Returns

res [OptimizeResult] `OptimizeResult` containing the following fields.

- **col_ind** [1-D array] Column indices corresponding to the best permutation found of the nodes of *B*.
- **fun** [float] The objective value of the solution.
- **nit** [int] The number of Frank-Wolfe iterations performed.

See also:

For documentation for the rest of the parameters, see `scipy.optimize.quadratic_assignment`

Options

maximize [bool (default: False)] Maximizes the objective function if `True`.

partial_match
[2-D array of integers, optional (default: None)] Fixes part of the matching. Also known as a "seed" [2].
Each row of *partial_match* specifies a pair of matched nodes: node `partial_match[i, 0]` of *A* is matched to node `partial_match[i, 1]` of *B*. The array has shape `(m, 2)`, where `m` is not greater than the number of nodes, n.

rng [{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional
If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

P0 [2-D array, "barycenter", or "randomized" (default: "barycenter")] Initial position. Must be a doubly-stochastic matrix [3].
If the initial position is an array, it must be a doubly stochastic matrix of size $m' \times m'$ where $m' = n - m$.
If `"barycenter"` (default), the initial position is the barycenter of the Birkhoff polytope (the space of doubly stochastic matrices). This is a $m' \times m'$ matrix with all entries equal to $1/m'$.
If `"randomized"` the initial search position is $P_0 = (J+K)/2$, where J is the barycenter and K is a random doubly stochastic matrix.

shuffle_input
[bool (default: False)] Set to *True* to resolve degenerate gradients randomly. For non-degenerate gradients this option has no effect.

maxiter [int, positive (default: 30)] Integer specifying the max number of Frank-Wolfe iterations performed.

tol [float (default: 0.03)] Tolerance for termination. Frank-Wolfe iteration terminates when $\frac{||P_i - P_{i+1}||_F}{\sqrt{m'}} \leq tol$, where i is the iteration number.

Notes

The algorithm may be sensitive to the initial permutation matrix (or search "position") due to the possibility of several local minima within the feasible region. A barycenter initialization is more likely to result in a better solution than a single random initialization. However, calling `quadratic_assignment` several times with different random initializations may result in a better optimum at the cost of longer total execution time.

References

[1], [2], [3]

Examples

As mentioned above, a barycenter initialization often results in a better solution than a single random initialization.

```
>>> from numpy.random import default_rng
>>> rng = default_rng()
>>> n = 15
>>> A = rng.random((n, n))
>>> B = rng.random((n, n))
>>> res = quadratic_assignment(A, B)  # FAQ is default method
>>> print(res.fun)
46.871483385480545  # may vary
```

```
>>> options = {"P0": "randomized"}  # use randomized initialization
>>> res = quadratic_assignment(A, B, options=options)
>>> print(res.fun)
47.224831071310625 # may vary
```

However, consider running from several randomized initializations and keeping the best result.

```
>>> res = min([quadratic_assignment(A, B, options=options)
...             for i in range(30)], key=lambda x: x.fun)
```

(continues on next page)

(continued from previous page)

```
>>> print(res.fun)
46.671852533681516 # may vary
```

The '2-opt' method can be used to further refine the results.

```
>>> options = {"partial_guess": np.array([np.arange(n), res.col_ind]).T}
>>> res = quadratic_assignment(A, B, method="2opt", options=options)
>>> print(res.fun)
46.47160735721583 # may vary
```

quadratic_assignment(method='2opt')

scipy.optimize.**quadratic_assignment**(*A*, *B*, *method='2opt'*, *options={'maximize': False, 'rng': None, 'partial_match': None, 'partial_guess': None}*)

Solve the quadratic assignment problem (approximately).

This function solves the Quadratic Assignment Problem (QAP) and the Graph Matching Problem (GMP) using the 2-opt algorithm [1].

Quadratic assignment solves problems of the following form:

$$\min_P \ \text{trace}(A^T P B P^T)$$
$$\text{s.t. } P \in \mathcal{P}$$

where $\mathcal{P}$ is the set of all permutation matrices, and A and B are square matrices.

Graph matching tries to *maximize* the same objective function. This algorithm can be thought of as finding the alignment of the nodes of two graphs that minimizes the number of induced edge disagreements, or, in the case of weighted graphs, the sum of squared edge weight differences.

Note that the quadratic assignment problem is NP-hard. The results given here are approximations and are not guaranteed to be optimal.

Parameters

A [2-D array, square] The square matrix A in the objective function above.
B [2-D array, square] The square matrix B in the objective function above.
method [str in {'faq', '2opt'} (default: 'faq')] The algorithm used to solve the problem. This is the method-specific documentation for '2opt'. *'faq'* is also available.

Returns

res [OptimizeResult] *OptimizeResult* containing the following fields.
- **col_ind** [1-D array] Column indices corresponding to the best permutation found of the nodes of *B*.
- **fun** [float] The objective value of the solution.
- **nit** [int] The number of iterations performed during optimization.

See also:

For documentation for the rest of the parameters, see *scipy.optimize.quadratic_assignment*

Options

maximize [bool (default: False)] Maximizes the objective function if `True`.
rng [{None, int, `numpy.random.Generator`,] `numpy.random.RandomState`}, optional

If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

partial_match
: [2-D array of integers, optional (default: None)] Fixes part of the matching. Also known as a "seed" [2].
Each row of *partial_match* specifies a pair of matched nodes: node `partial_match[i, 0]` of *A* is matched to node `partial_match[i, 1]` of *B*. The array has shape `(m, 2)`, where `m` is not greater than the number of nodes, n.

partial_guess
: [2-D array of integers, optional (default: None)] A guess for the matching between the two matrices. Unlike *partial_match*, *partial_guess* does not fix the indices; they are still free to be optimized.
Each row of *partial_guess* specifies a pair of matched nodes: node `partial_guess[i, 0]` of *A* is matched to node `partial_guess[i, 1]` of *B*. The array has shape `(m, 2)`, where `m` is not greater than the number of nodes, n.

Notes

This is a greedy algorithm that works similarly to bubble sort: beginning with an initial permutation, it iteratively swaps pairs of indices to improve the objective function until no such improvements are possible.

[1], [2]

Utilities

Finite-difference approximation

approx_fprime(xk, f, epsilon, *args)	Finite-difference approximation of the gradient of a scalar function.
check_grad(func, grad, x0, *args, **kwargs)	Check the correctness of a gradient function by comparing it against a (forward) finite-difference approximation of the gradient.

scipy.optimize.approx_fprime

`scipy.optimize.`**`approx_fprime`**(*xk*, *f*, *epsilon*, **args*)
Finite-difference approximation of the gradient of a scalar function.

Parameters

xk [array_like] The coordinate vector at which to determine the gradient of *f*.

f [callable] The function of which to determine the gradient (partial derivatives). Should take *xk* as first argument, other arguments to *f* can be supplied in `*args`. Should return a scalar, the value of the function at *xk*.

epsilon [array_like] Increment to *xk* to use for determining the function gradient. If a scalar, uses the same finite difference delta for all partial derivatives. If an array, should contain one value per element of *xk*.

***args** [args, optional] Any other arguments that are to be passed to *f*.

Returns

grad [ndarray] The partial derivatives of f to xk.

See also:

`check_grad`

Check correctness of gradient function against approx_fprime.

Notes

The function gradient is determined by the forward finite difference formula:

```
             f(xk[i] + epsilon[i]) - f(xk[i])
f'[i] = ---------------------------------
                        epsilon[i]
```

The main use of *approx_fprime* is in scalar function optimizers like *fmin_bfgs*, to determine numerically the Jacobian of a function.

Examples

```
>>> from scipy import optimize
>>> def func(x, c0, c1):
...     "Coordinate vector `x` should be an array of size two."
...     return c0 * x[0]**2 + c1*x[1]**2
```

```
>>> x = np.ones(2)
>>> c0, c1 = (1, 200)
>>> eps = np.sqrt(np.finfo(float).eps)
>>> optimize.approx_fprime(x, func, [eps, np.sqrt(200) * eps], c0, c1)
array([   2.        ,  400.00004198])
```

scipy.optimize.check_grad

scipy.optimize.**check_grad**(*func*, *grad*, *x0*, **args*, ***kwargs*)

Check the correctness of a gradient function by comparing it against a (forward) finite-difference approximation of the gradient.

Parameters

func [callable `func(x0, *args)`] Function whose derivative is to be checked.

grad [callable `grad(x0, *args)`] Gradient of *func*.

x0 [ndarray] Points to check *grad* against forward difference approximation of grad using *func*.

args [*args, optional] Extra arguments passed to *func* and *grad*.

epsilon [float, optional] Step size used for the finite difference approximation. It defaults to `sqrt(np.finfo(float).eps)`, which is approximately 1.49e-08.

Returns

err [float] The square root of the sum of squares (i.e., the 2-norm) of the difference between `grad(x0, *args)` and the finite difference approximation of *grad* using func at the points *x0*.

See also:

`approx_fprime`

Examples

```
>>> def func(x):
...     return x[0]**2 - 0.5 * x[1]**3
>>> def grad(x):
...     return [2 * x[0], -1.5 * x[1]**2]
>>> from scipy.optimize import check_grad
>>> check_grad(func, grad, [1.5, -1.5])
2.9802322387695312e-08
```

Line search

bracket(func[, xa, xb, args, grow_limit, …])	Bracket the minimum of the function.
line_search(f, myfprime, xk, pk[, gfk, …])	Find alpha that satisfies strong Wolfe conditions.

scipy.optimize.bracket

scipy.optimize.**bracket**(*func*, *xa=0.0*, *xb=1.0*, *args=()*, *grow_limit=110.0*, *maxiter=1000*)

Bracket the minimum of the function.

Given a function and distinct initial points, search in the downhill direction (as defined by the initial points) and return new points xa, xb, xc that bracket the minimum of the function f(xa) > f(xb) < f(xc). It doesn't always mean that obtained solution will satisfy xa<=x<=xb.

Parameters

func	[callable f(x,*args)] Objective function to minimize.
xa, xb	[float, optional] Bracketing interval. Defaults *xa* to 0.0, and *xb* to 1.0.
args	[tuple, optional] Additional arguments (if present), passed to *func*.
grow_limit	[float, optional] Maximum grow limit. Defaults to 110.0
maxiter	[int, optional] Maximum number of iterations to perform. Defaults to 1000.

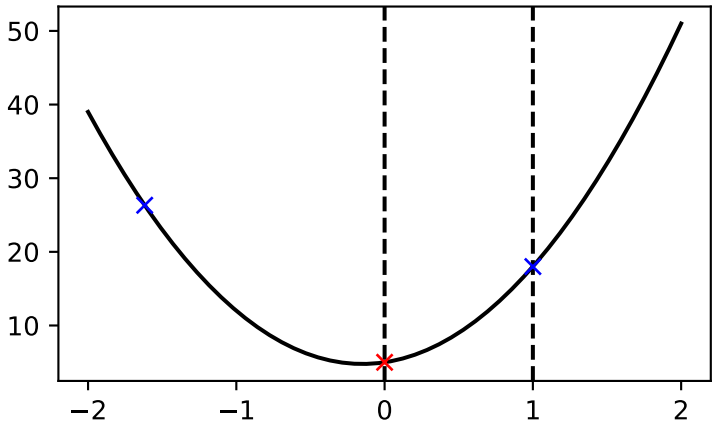
Returns

xa, xb, xc	[float] Bracket.
fa, fb, fc	[float] Objective function values in bracket.
funcalls	[int] Number of function evaluations made.

Examples

This function can find a downward convex region of a function:

```
>>> import matplotlib.pyplot as plt
>>> from scipy.optimize import bracket
>>> def f(x):
...     return 10*x**2 + 3*x + 5
>>> x = np.linspace(-2, 2)
>>> y = f(x)
>>> init_xa, init_xb = 0, 1
>>> xa, xb, xc, fa, fb, fc, funcalls = bracket(f, xa=init_xa, xb=init_xb)
>>> plt.axvline(x=init_xa, color="k", linestyle="--")
>>> plt.axvline(x=init_xb, color="k", linestyle="--")
>>> plt.plot(x, y, "-k")
>>> plt.plot(xa, fa, "bx")
>>> plt.plot(xb, fb, "rx")
>>> plt.plot(xc, fc, "bx")
>>> plt.show()
```



scipy.optimize.line_search

scipy.optimize.**line_search**(*f*, *myfprime*, *xk*, *pk*, *gfk=None*, *old_fval=None*, *old_old_fval=None*, *args=()*, *c1=0.0001*, *c2=0.9*, *amax=None*, *extra_condition=None*, *maxiter=10*)

Find alpha that satisfies strong Wolfe conditions.

Parameters

f	[callable f(x,*args)] Objective function.
myfprime	[callable f'(x,*args)] Objective function gradient.
xk	[ndarray] Starting point.
pk	[ndarray] Search direction.
gfk	[ndarray, optional] Gradient value for x=xk (xk being the current parameter estimate). Will be recomputed if omitted.

old_fval [float, optional] Function value for x=xk. Will be recomputed if omitted.
old_old_fval
[float, optional] Function value for the point preceding x=xk.
args [tuple, optional] Additional arguments passed to objective function.
c1 [float, optional] Parameter for Armijo condition rule.
c2 [float, optional] Parameter for curvature condition rule.
amax [float, optional] Maximum step size
extra_condition
[callable, optional] A callable of the form `extra_condition(alpha, x, f, g)` returning a boolean. Arguments are the proposed step `alpha` and the corresponding `x`, `f` and `g` values. The line search accepts the value of `alpha` only if this callable returns `True`. If the callable returns `False` for the step length, the algorithm will continue with new iterates. The callable is only called for iterates satisfying the strong Wolfe conditions.
maxiter [int, optional] Maximum number of iterations to perform.

Returns

alpha [float or None] Alpha for which `x_new = x0 + alpha * pk`, or None if the line search algorithm did not converge.
fc [int] Number of function evaluations made.
gc [int] Number of gradient evaluations made.
new_fval [float or None] New function value `f(x_new)=f(x0+alpha*pk)`, or None if the line search algorithm did not converge.
old_fval [float] Old function value `f(x0)`.
new_slope [float or None] The local slope along the search direction at the new value `<myfprime(x_new), pk>`, or None if the line search algorithm did not converge.

Notes

Uses the line search algorithm to enforce strong Wolfe conditions. See Wright and Nocedal, 'Numerical Optimization', 1999, pp. 59-61.

Examples

```
>>> from scipy.optimize import line_search
```

A objective function and its gradient are defined.

```
>>> def obj_func(x):
...     return (x[0])**2+(x[1])**2
>>> def obj_grad(x):
...     return [2*x[0], 2*x[1]]
```

We can find alpha that satisfies strong Wolfe conditions.

```
>>> start_point = np.array([1.8, 1.7])
>>> search_gradient = np.array([-1.0, -1.0])
>>> line_search(obj_func, obj_grad, start_point, search_gradient)
(1.0, 2, 1, 1.1300000000000001, 6.13, [1.6, 1.4])
```

Hessian approximation

LbfgsInvHessProduct(*args, **kwargs)	Linear operator for the L-BFGS approximate inverse Hessian.
HessianUpdateStrategy()	Interface for implementing Hessian update strategies.

scipy.optimize.LbfgsInvHessProduct

class scipy.optimize.**LbfgsInvHessProduct**(**args*, ***kwargs*)

Linear operator for the L-BFGS approximate inverse Hessian.

This operator computes the product of a vector with the approximate inverse of the Hessian of the objective function, using the L-BFGS limited memory approximation to the inverse Hessian, accumulated during the optimization.

Objects of this class implement the `scipy.sparse.linalg.LinearOperator` interface.

Parameters

sk [array_like, shape=(n_corr, n)] Array of *n_corr* most recent updates to the solution vector. (See [1]).

yk [array_like, shape=(n_corr, n)] Array of *n_corr* most recent updates to the gradient. (See [1]).

References

[1]

Attributes

H Hermitian adjoint.

T Transpose this linear operator.

Methods

__call__(x)	Call self as a function.
adjoint()	Hermitian adjoint.
dot(x)	Matrix-matrix or matrix-vector multiplication.
matmat(X)	Matrix-matrix multiplication.
matvec(x)	Matrix-vector multiplication.
rmatmat(X)	Adjoint matrix-matrix multiplication.
rmatvec(x)	Adjoint matrix-vector multiplication.
todense()	Return a dense array representation of this operator.
transpose()	Transpose this linear operator.

scipy.optimize.LbfgsInvHessProduct.__call__

LbfgsInvHessProduct.**__call__**(*x*)
Call self as a function.

scipy.optimize.LbfgsInvHessProduct.adjoint

LbfgsInvHessProduct.**adjoint**()
Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated self.H instead of self.adjoint().

Returns

A_H [LinearOperator] Hermitian adjoint of self.

scipy.optimize.LbfgsInvHessProduct.dot

LbfgsInvHessProduct.**dot**(*x*)
Matrix-matrix or matrix-vector multiplication.

Parameters

x [array_like] 1-d or 2-d array, representing a vector or matrix.

Returns

Ax [array] 1-d or 2-d array (depending on the shape of x) that represents the result of applying this linear operator on x.

scipy.optimize.LbfgsInvHessProduct.matmat

LbfgsInvHessProduct.**matmat**(*X*)
Matrix-matrix multiplication.

Performs the operation y=A*X where A is an MxN linear operator and X dense N*K matrix or ndarray.

Parameters

X [{matrix, ndarray}] An array with shape (N,K).

Returns

Y [{matrix, ndarray}] A matrix or ndarray with shape (M,K) depending on the type of the X argument.

Notes

This matmat wraps any user-specified matmat routine or overridden _matmat method to ensure that y has the correct type.

scipy.optimize.LbfgsInvHessProduct.matvec

LbfgsInvHessProduct.**matvec**(*x*)

Matrix-vector multiplication.

Performs the operation y=A*x where A is an MxN linear operator and x is a column vector or 1-d array.

Parameters

x [{matrix, ndarray}] An array with shape (N,) or (N,1).

Returns

y [{matrix, ndarray}] A matrix or ndarray with shape (M,) or (M,1) depending on the type and shape of the x argument.

Notes

This matvec wraps the user-specified matvec routine or overridden _matvec method to ensure that y has the correct shape and type.

scipy.optimize.LbfgsInvHessProduct.rmatmat

LbfgsInvHessProduct.**rmatmat**(*X*)

Adjoint matrix-matrix multiplication.

Performs the operation y = A^H * x where A is an MxN linear operator and x is a column vector or 1-d array, or 2-d array. The default implementation defers to the adjoint.

Parameters

X [{matrix, ndarray}] A matrix or 2D array.

Returns

Y [{matrix, ndarray}] A matrix or 2D array depending on the type of the input.

Notes

This rmatmat wraps the user-specified rmatmat routine.

scipy.optimize.LbfgsInvHessProduct.rmatvec

LbfgsInvHessProduct.**rmatvec**(*x*)

Adjoint matrix-vector multiplication.

Performs the operation y = A^H * x where A is an MxN linear operator and x is a column vector or 1-d array.

Parameters

x [{matrix, ndarray}] An array with shape (M,) or (M,1).

Returns

y [{matrix, ndarray}] A matrix or ndarray with shape (N,) or (N,1) depending on the type and shape of the x argument.

Notes

This rmatvec wraps the user-specified rmatvec routine or overridden _rmatvec method to ensure that y has the correct shape and type.

scipy.optimize.LbfgsInvHessProduct.todense

LbfgsInvHessProduct.**todense**()

Return a dense array representation of this operator.

Returns

arr [ndarray, shape=(n, n)] An array with the same shape and containing the same data represented by this *LinearOperator*.

scipy.optimize.LbfgsInvHessProduct.transpose

LbfgsInvHessProduct.**transpose**()

Transpose this linear operator.

Returns a LinearOperator that represents the transpose of this one. Can be abbreviated self.T instead of self.transpose().

__mul__	

scipy.optimize.HessianUpdateStrategy

class scipy.optimize.**HessianUpdateStrategy**

Interface for implementing Hessian update strategies.

Many optimization methods make use of Hessian (or inverse Hessian) approximations, such as the quasi-Newton methods BFGS, SR1, L-BFGS. Some of these approximations, however, do not actually need to store the entire matrix or can compute the internal matrix product with a given vector in a very efficiently manner. This class serves as an abstract interface between the optimization algorithm and the quasi-Newton update strategies, giving freedom of implementation to store and update the internal matrix as efficiently as possible. Different choices of initialization and update procedure will result in different quasi-Newton strategies.

Four methods should be implemented in derived classes: `initialize`, `update`, `dot` and `get_matrix`.

Notes

Any instance of a class that implements this interface, can be accepted by the method `minimize` and used by the compatible solvers to approximate the Hessian (or inverse Hessian) used by the optimization algorithms.

Methods

dot(p)	Compute the product of the internal matrix with the given vector.
get_matrix()	Return current internal matrix.
initialize(n, approx_type)	Initialize internal matrix.
update(delta_x, delta_grad)	Update internal matrix.

scipy.optimize.HessianUpdateStrategy.dot

HessianUpdateStrategy.**dot**(*p*)

Compute the product of the internal matrix with the given vector.

Parameters

p [array_like] 1-D array representing a vector.

Returns

Hp [array] 1-D represents the result of multiplying the approximation matrix by vector p.

scipy.optimize.HessianUpdateStrategy.get_matrix

HessianUpdateStrategy.**get_matrix**()

Return current internal matrix.

Returns

H [ndarray, shape (n, n)] Dense matrix containing either the Hessian or its inverse (depending on how 'approx_type' is defined).

scipy.optimize.HessianUpdateStrategy.initialize

HessianUpdateStrategy.**initialize**(*n*, *approx_type*)

Initialize internal matrix.

Allocate internal memory for storing and updating the Hessian or its inverse.

Parameters

n [int] Problem dimension.

approx_type

[{'hess', 'inv_hess'}] Selects either the Hessian or the inverse Hessian. When set to 'hess' the Hessian will be stored and updated. When set to 'inv_hess' its inverse will be used instead.

scipy.optimize.HessianUpdateStrategy.update

HessianUpdateStrategy.**update**(*delta_x*, *delta_grad*)

Update internal matrix.

Update Hessian matrix or its inverse (depending on how 'approx_type' is defined) using information about the last evaluated points.

Parameters

delta_x [ndarray] The difference between two points the gradient function have been evaluated at: `delta_x = x2 - x1`.

delta_grad [ndarray] The difference between the gradients: `delta_grad = grad(x2) - grad(x1)`.

Benchmark problems

rosen(x)	The Rosenbrock function.
rosen_der(x)	The derivative (i.e.
rosen_hess(x)	The Hessian matrix of the Rosenbrock function.
rosen_hess_prod(x, p)	Product of the Hessian matrix of the Rosenbrock function with a vector.

scipy.optimize.rosen

scipy.optimize.**rosen**(*x*)

The Rosenbrock function.

The function computed is:

```
sum(100.0*(x[1:] - x[:-1]**2.0)**2.0 + (1 - x[:-1])**2.0)
```

Parameters

x [array_like] 1-D array of points at which the Rosenbrock function is to be computed.

Returns

f [float] The value of the Rosenbrock function.

See also:

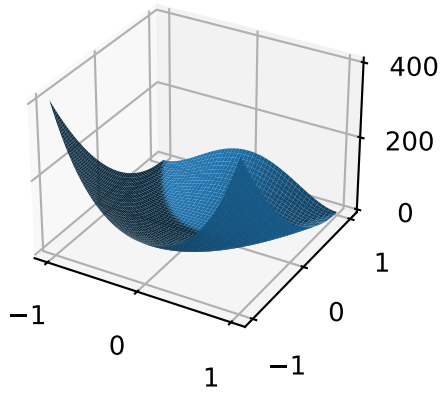
rosen_der, **rosen_hess**, **rosen_hess_prod**

Examples

```
>>> from scipy.optimize import rosen
>>> X = 0.1 * np.arange(10)
>>> rosen(X)
76.56
```

For higher-dimensional input `rosen` broadcasts. In the following example, we use this to plot a 2D landscape. Note that `rosen_hess` does not broadcast in this manner.

```
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.mplot3d import Axes3D
>>> x = np.linspace(-1, 1, 50)
>>> X, Y = np.meshgrid(x, x)
>>> ax = plt.subplot(111, projection='3d')
>>> ax.plot_surface(X, Y, rosen([X, Y]))
>>> plt.show()
```



scipy.optimize.rosen_der

scipy.optimize.**rosen_der**(*x*)

The derivative (i.e. gradient) of the Rosenbrock function.

Parameters

x [array_like] 1-D array of points at which the derivative is to be computed.

Returns

rosen_der [(N,) ndarray] The gradient of the Rosenbrock function at *x*.

See also:

rosen, **rosen_hess**, **rosen_hess_prod**

Examples

```
>>> from scipy.optimize import rosen_der
>>> X = 0.1 * np.arange(9)
>>> rosen_der(X)
array([ -2. ,  10.6,  15.6,  13.4,   6.4,  -3. , -12.4, -19.4,  62. ])
```

scipy.optimize.rosen_hess

scipy.optimize.**rosen_hess**(*x*)

The Hessian matrix of the Rosenbrock function.

Parameters

x [array_like] 1-D array of points at which the Hessian matrix is to be computed.

Returns

rosen_hess [ndarray] The Hessian matrix of the Rosenbrock function at *x*.

See also:

rosen, **rosen_der**, **rosen_hess_prod**

Examples

```
>>> from scipy.optimize import rosen_hess
>>> X = 0.1 * np.arange(4)
>>> rosen_hess(X)
array([[-38.,   0.,   0.,   0.],
       [  0., 134., -40.,   0.],
       [  0., -40., 130., -80.],
       [  0.,   0., -80., 200.]])
```

scipy.optimize.rosen_hess_prod

scipy.optimize.**rosen_hess_prod**(*x*, *p*)

Product of the Hessian matrix of the Rosenbrock function with a vector.

Parameters

x [array_like] 1-D array of points at which the Hessian matrix is to be computed.

p [array_like] 1-D array, the vector to be multiplied by the Hessian matrix.

Returns

rosen_hess_prod [ndarray] The Hessian matrix of the Rosenbrock function at *x* multiplied by the vector *p*.

See also:

rosen, **rosen_der**, **rosen_hess**

Examples

```
>>> from scipy.optimize import rosen_hess_prod
>>> X = 0.1 * np.arange(9)
>>> p = 0.5 * np.arange(9)
>>> rosen_hess_prod(X, p)
array([  -0.,   27.,  -10.,  -95., -192., -265., -278., -195., -180.])
```

Legacy functions

The functions below are not recommended for use in new scripts; all of these methods are accessible via a newer, more consistent interfaces, provided by the interfaces above.

Optimization

General-purpose multivariate methods:

fmin(func, x0[, args, xtol, ftol, maxiter, …])	Minimize a function using the downhill simplex algorithm.
fmin_powell(func, x0[, args, xtol, ftol, …])	Minimize a function using modified Powell's method.
fmin_cg(f, x0[, fprime, args, gtol, norm, …])	Minimize a function using a nonlinear conjugate gradient algorithm.
fmin_bfgs(f, x0[, fprime, args, gtol, norm, …])	Minimize a function using the BFGS algorithm.
fmin_ncg(f, x0, fprime[, fhess_p, fhess, …])	Unconstrained minimization of a function using the Newton-CG method.

scipy.optimize.fmin

scipy.optimize.**fmin**(*func*, *x0*, *args=()*, *xtol=0.0001*, *ftol=0.0001*, *maxiter=None*, *maxfun=None*, *full_output=0*, *disp=1*, *retall=0*, *callback=None*, *initial_simplex=None*)

Minimize a function using the downhill simplex algorithm.

This algorithm only uses function values, not derivatives or second derivatives.

Parameters

func [callable func(x,*args)] The objective function to be minimized.

x0 [ndarray] Initial guess.

args [tuple, optional] Extra arguments passed to func, i.e., `f(x,*args)`.

xtol [float, optional] Absolute error in xopt between iterations that is acceptable for convergence.

ftol [number, optional] Absolute error in func(xopt) between iterations that is acceptable for convergence.

maxiter [int, optional] Maximum number of iterations to perform.

maxfun [number, optional] Maximum number of function evaluations to make.

full_output [bool, optional] Set to True if fopt and warnflag outputs are desired.

disp [bool, optional] Set to True to print convergence messages.

retall [bool, optional] Set to True to return list of solutions at each iteration.

callback [callable, optional] Called after each iteration, as callback(xk), where xk is the current parameter vector.

initial_simplex

[array_like of shape (N + 1, N), optional] Initial simplex. If given, overrides *x0*. `initial_simplex[j,:]` should contain the coordinates of the jth vertex of the `N+1` vertices in the simplex, where `N` is the dimension.

Returns

xopt	[ndarray] Parameter that minimizes function.
fopt	[float] Value of function at minimum: `fopt = func(xopt)`.
iter	[int] Number of iterations performed.
funcalls	[int] Number of function calls made.
warnflag	[int] 1 : Maximum number of function evaluations made. 2 : Maximum number of iterations reached.
allvecs	[list] Solution at each iteration.

See also:

minimize

Interface to minimization algorithms for multivariate functions. See the 'Nelder-Mead' *method* in particular.

Notes

Uses a Nelder-Mead simplex algorithm to find the minimum of function of one or more variables.

This algorithm has a long history of successful use in applications. But it will usually be slower than an algorithm that uses first or second derivative information. In practice, it can have poor performance in high-dimensional problems and is not robust to minimizing complicated functions. Additionally, there currently is no complete theory describing when the algorithm will successfully converge to the minimum, or how fast it will if it does. Both the ftol and xtol criteria must be met for convergence.

References

[1], [2]

Examples

```
>>> def f(x):
...     return x**2
```

```
>>> from scipy import optimize
```

```
>>> minimum = optimize.fmin(f, 1)
Optimization terminated successfully.
         Current function value: 0.000000
         Iterations: 17
         Function evaluations: 34
>>> minimum[0]
-8.8817841970012523e-16
```

scipy.optimize.fmin_powell

scipy.optimize.**fmin_powell**(*func*, *x0*, *args=()*, *xtol=0.0001*, *ftol=0.0001*, *maxiter=None*, *maxfun=None*, *full_output=0*, *disp=1*, *retall=0*, *callback=None*, *direc=None*)

Minimize a function using modified Powell's method.

This method only uses function values, not derivatives.

Parameters

func [callable f(x,*args)] Objective function to be minimized.
x0 [ndarray] Initial guess.
args [tuple, optional] Extra arguments passed to func.
xtol [float, optional] Line-search error tolerance.
ftol [float, optional] Relative error in `func(xopt)` acceptable for convergence.
maxiter [int, optional] Maximum number of iterations to perform.
maxfun [int, optional] Maximum number of function evaluations to make.
full_output [bool, optional] If True, `fopt`, `xi`, `direc`, `iter`, `funcalls`, and `warnflag` are returned.
disp [bool, optional] If True, print convergence messages.
retall [bool, optional] If True, return a list of the solution at each iteration.
callback [callable, optional] An optional user-supplied function, called after each iteration. Called as `callback(xk)`, where `xk` is the current parameter vector.
direc [ndarray, optional] Initial fitting step and parameter order set as an (N, N) array, where N is the number of fitting parameters in *x0*. Defaults to step size 1.0 fitting all parameters simultaneously (`np.eye((N, N))`). To prevent initial consideration of values in a step or to change initial step size, set to 0 or desired step size in the Jth position in the Mth block, where J is the position in *x0* and M is the desired evaluation step, with steps being evaluated in index order. Step size and ordering will change freely as minimization proceeds.

Returns

xopt [ndarray] Parameter which minimizes *func*.
fopt [number] Value of function at minimum: `fopt = func(xopt)`.
direc [ndarray] Current direction set.
iter [int] Number of iterations.
funcalls [int] Number of function calls made.
warnflag [int]
Integer warning flag:
1 : Maximum number of function evaluations. 2 : Maximum number of iterations. 3 : NaN result encountered. 4 : The result is out of the provided bounds.
allvecs [list] List of solutions at each iteration.

See also:

minimize

Interface to unconstrained minimization algorithms for multivariate functions. See the 'Powell' method in particular.

Notes

Uses a modification of Powell's method to find the minimum of a function of N variables. Powell's method is a conjugate direction method.

The algorithm has two loops. The outer loop merely iterates over the inner loop. The inner loop minimizes over each current direction in the direction set. At the end of the inner loop, if certain conditions are met, the direction that gave the largest decrease is dropped and replaced with the difference between the current estimated x and the estimated x from the beginning of the inner-loop.

The technical conditions for replacing the direction of greatest increase amount to checking that

1. No further gain can be made along the direction of greatest increase from that iteration.
2. The direction of greatest increase accounted for a large sufficient fraction of the decrease in the function value from that iteration of the inner loop.

Examples

```
>>> def f(x):
...     return x**2
```

```
>>> from scipy import optimize
```

```
>>> minimum = optimize.fmin_powell(f, -1)
Optimization terminated successfully.
         Current function value: 0.000000
         Iterations: 2
         Function evaluations: 18
>>> minimum
array(0.0)
```

scipy.optimize.fmin_cg

scipy.optimize.**fmin_cg**(*f*, *x0*, *fprime=None*, *args=()*, *gtol=1e-05*, *norm=inf*, *epsilon=1.4901161193847656e-08*, *maxiter=None*, *full_output=0*, *disp=1*, *retall=0*, *callback=None*)

Minimize a function using a nonlinear conjugate gradient algorithm.

Parameters

f [callable, `f(x, *args)`] Objective function to be minimized. Here *x* must be a 1-D array of the variables that are to be changed in the search for a minimum, and *args* are the other (fixed) parameters of *f*.

x0 [ndarray] A user-supplied initial estimate of *xopt*, the optimal value of *x*. It must be a 1-D array of values.

fprime [callable, `fprime(x, *args)`, optional] A function that returns the gradient of *f* at *x*. Here *x* and *args* are as described above for *f*. The returned value must be a 1-D array. Defaults to None, in which case the gradient is approximated numerically (see *epsilon*, below).

args [tuple, optional] Parameter values passed to *f* and *fprime*. Must be supplied whenever additional fixed parameters are needed to completely specify the functions *f* and *fprime*.

gtol [float, optional] Stop when the norm of the gradient is less than *gtol*.

norm [float, optional] Order to use for the norm of the gradient (`-np.Inf` is min, `np.Inf` is max).

epsilon [float or ndarray, optional] Step size(s) to use when *fprime* is approximated numerically. Can be a scalar or a 1-D array. Defaults to `sqrt(eps)`, with eps the floating point machine precision. Usually `sqrt(eps)` is about 1.5e-8.

maxiter [int, optional] Maximum number of iterations to perform. Default is `200 * len(x0)`.

full_output [bool, optional] If True, return *fopt*, *func_calls*, *grad_calls*, and *warnflag* in addition to *xopt*. See the Returns section below for additional information on optional return values.

disp [bool, optional] If True, return a convergence message, followed by *xopt*.

retall [bool, optional] If True, add to the returned values the results of each iteration.

callback [callable, optional] An optional user-supplied function, called after each iteration. Called as `callback(xk)`, where `xk` is the current value of *x0*.

Returns

xopt [ndarray] Parameters which minimize f, i.e., `f(xopt) == fopt`.

fopt [float, optional] Minimum value found, f(xopt). Only returned if *full_output* is True.

func_calls [int, optional] The number of function_calls made. Only returned if *full_output* is True.

grad_calls [int, optional] The number of gradient calls made. Only returned if *full_output* is True.

warnflag [int, optional] Integer value with warning status, only returned if *full_output* is True.
0 : Success.
1 : The maximum number of iterations was exceeded.
2 [Gradient and/or function calls were not changing. May indicate] that precision was lost, i.e., the routine did not converge.
3 : NaN result encountered.

allvecs [list of ndarray, optional] List of arrays, containing the results at each iteration. Only returned if *retall* is True.

See also:

`minimize`

common interface to all *`scipy.optimize`* algorithms for unconstrained and constrained minimization of multivariate functions. It provides an alternative way to call `fmin_cg`, by specifying `method='CG'`.

Notes

This conjugate gradient algorithm is based on that of Polak and Ribiere [1].

Conjugate gradient methods tend to work better when:

1. *f* has a unique global minimizing point, and no local minima or other stationary points,
2. *f* is, at least locally, reasonably well approximated by a quadratic function of the variables,
3. *f* is continuous and has a continuous gradient,
4. *fprime* is not too large, e.g., has a norm less than 1000,
5. The initial guess, *x0*, is reasonably close to *f* 's global minimizing point, *xopt*.

References

[1]

Examples

Example 1: seek the minimum value of the expression `a*u**2 + b*u*v + c*v**2 + d*u + e*v + f` for given values of the parameters and an initial guess `(u, v) = (0, 0)`.

```
>>> args = (2, 3, 7, 8, 9, 10)  # parameter values
>>> def f(x, *args):
...     u, v = x
...     a, b, c, d, e, f = args
...     return a*u**2 + b*u*v + c*v**2 + d*u + e*v + f
>>> def gradf(x, *args):
...     u, v = x
...     a, b, c, d, e, f = args
...     gu = 2*a*u + b*v + d     # u-component of the gradient
...     gv = b*u + 2*c*v + e     # v-component of the gradient
...     return np.asarray((gu, gv))
>>> x0 = np.asarray((0, 0))  # Initial guess.
>>> from scipy import optimize
>>> res1 = optimize.fmin_cg(f, x0, fprime=gradf, args=args)
Optimization terminated successfully.
         Current function value: 1.617021
         Iterations: 4
         Function evaluations: 8
         Gradient evaluations: 8
>>> res1
array([-1.80851064, -0.25531915])
```

Example 2: solve the same problem using the *minimize* function. (This *myopts* dictionary shows all of the available options, although in practice only non-default values would be needed. The returned value will be a dictionary.)

```
>>> opts = {'maxiter' : None,    # default value.
...         'disp' : True,    # non-default value.
...         'gtol' : 1e-5,    # default value.
...         'norm' : np.inf,  # default value.
...         'eps' : 1.4901161193847656e-08}  # default value.
>>> res2 = optimize.minimize(f, x0, jac=gradf, args=args,
...                          method='CG', options=opts)
Optimization terminated successfully.
        Current function value: 1.617021
        Iterations: 4
        Function evaluations: 8
        Gradient evaluations: 8
>>> res2.x  # minimum found
array([-1.80851064, -0.25531915])
```

scipy.optimize.fmin_bfgs

scipy.optimize.**fmin_bfgs**(*f*, *x0*, *fprime=None*, *args=()*, *gtol=1e-05*, *norm=inf*, *epsilon=1.4901161193847656e-08*, *maxiter=None*, *full_output=0*, *disp=1*, *retall=0*, *callback=None*)

Minimize a function using the BFGS algorithm.

Parameters

f	[callable `f(x,*args)`] Objective function to be minimized.
x0	[ndarray] Initial guess.
fprime	[callable `f'(x,*args)`, optional] Gradient of f.
args	[tuple, optional] Extra arguments passed to f and fprime.
gtol	[float, optional] Gradient norm must be less than *gtol* before successful termination.
norm	[float, optional] Order of norm (Inf is max, -Inf is min)
epsilon	[int or ndarray, optional] If *fprime* is approximated, use this value for the step size.
callback	[callable, optional] An optional user-supplied function to call after each iteration. Called as `callback(xk)`, where `xk` is the current parameter vector.
maxiter	[int, optional] Maximum number of iterations to perform.
full_output	[bool, optional] If True, return `fopt`, `func_calls`, `grad_calls`, and `warnflag` in addition to `xopt`.
disp	[bool, optional] Print convergence message if True.
retall	[bool, optional] Return a list of results at each iteration if True.

Returns

xopt	[ndarray] Parameters which minimize f, i.e., `f(xopt) == fopt`.
fopt	[float] Minimum value.
gopt	[ndarray] Value of gradient at minimum, f'(xopt), which should be near 0.
Bopt	[ndarray] Value of 1/f''(xopt), i.e., the inverse Hessian matrix.
func_calls	[int] Number of function_calls made.
grad_calls	[int] Number of gradient calls made.
warnflag	[integer] 1 : Maximum number of iterations exceeded. 2 : Gradient and/or function calls not changing. 3 : NaN result encountered.
allvecs	[list] The value of *xopt* at each iteration. Only returned if *retall* is True.

array([ 2.85169950e-06, -4.61820139e-07])
```

```
>>> def quadratic_cost_grad(x, Q):
...     return 2 * Q @ x
...
>>> fmin_bfgs(quadratic_cost, x0, quadratic_cost_grad, args=(cost_weight,
 ↪))
Optimization terminated successfully.
        Current function value: 0.000000
        Iterations: 7
        Function evaluations: 8
        Gradient evaluations: 8
array([ 2.85916637e-06, -4.54371951e-07])
```

scipy.optimize.fmin_ncg

scipy.optimize.**fmin_ncg**(*f*, *x0*, *fprime*, *fhess_p=None*, *fhess=None*, *args=()*, *avextol=1e-05*, *epsilon=1.4901161193847656e-08*, *maxiter=None*, *full_output=0*, *disp=1*, *retall=0*, *callback=None*)

Unconstrained minimization of a function using the Newton-CG method.

Parameters

f	[callable `f(x, *args)`] Objective function to be minimized.
x0	[ndarray] Initial guess.
fprime	[callable `f'(x, *args)`] Gradient of f.
fhess_p	[callable `fhess_p(x, p, *args)`, optional] Function which computes the Hessian of f times an arbitrary vector, p.
fhess	[callable `fhess(x, *args)`, optional] Function to compute the Hessian matrix of f.
args	[tuple, optional] Extra arguments passed to f, fprime, fhess_p, and fhess (the same set of extra arguments is supplied to all of these functions).
epsilon	[float or ndarray, optional] If fhess is approximated, use this value for the step size.

callback [callable, optional] An optional user-supplied function which is called after each iteration. Called as callback(xk), where xk is the current parameter vector.
avextol [float, optional] Convergence is assumed when the average relative error in the minimizer falls below this amount.
maxiter [int, optional] Maximum number of iterations to perform.
full_output [bool, optional] If True, return the optional outputs.
disp [bool, optional] If True, print convergence message.
retall [bool, optional] If True, return a list of results at each iteration.

Returns

xopt [ndarray] Parameters which minimize f, i.e., `f(xopt) == fopt`.
fopt [float] Value of the function at xopt, i.e., `fopt = f(xopt)`.
fcalls [int] Number of function calls made.
gcalls [int] Number of gradient calls made.
hcalls [int] Number of Hessian calls made.
warnflag [int] Warnings generated by the algorithm. 1 : Maximum number of iterations exceeded. 2 : Line search failure (precision loss). 3 : NaN result encountered.
allvecs [list] The result at each iteration, if retall is True (see below).

See also:

`minimize`

Interface to minimization algorithms for multivariate functions. See the 'Newton-CG' *method* in particular.

Notes

Only one of *fhess_p* or *fhess* need to be given. If *fhess* is provided, then *fhess_p* will be ignored. If neither *fhess* nor *fhess_p* is provided, then the hessian product will be approximated using finite differences on *fprime*. *fhess_p* must compute the hessian times an arbitrary vector. If it is not given, finite-differences on *fprime* are used to compute it.

Newton-CG methods are also called truncated Newton methods. This function differs from scipy.optimize.fmin_tnc because

1. ***scipy.optimize.fmin_ncg is written purely in Python using NumPy***

   and scipy while scipy.optimize.fmin_tnc calls a C function.

2. ***scipy.optimize.fmin_ncg is only for unconstrained minimization***

   while scipy.optimize.fmin_tnc is for unconstrained minimization or box constrained minimization. (Box constraints give lower and upper bounds for each variable separately.)

scipy.optimize.fmin_l_bfgs_b

scipy.optimize.**fmin_l_bfgs_b**(*func*, *x0*, *fprime=None*, *args=()*, *approx_grad=0*, *bounds=None*, *m=10*, *factr=10000000.0*, *pgtol=1e-05*, *epsilon=1e-08*, *iprint=-1*, *maxfun=15000*, *maxiter=15000*, *disp=None*, *callback=None*, *maxls=20*)

Minimize a function func using the L-BFGS-B algorithm.

Parameters

func [callable f(x,*args)] Function to minimize.

x0 [ndarray] Initial guess.

fprime [callable fprime(x,*args), optional] The gradient of *func*. If None, then *func* returns the function value and the gradient (`f, g = func(x, *args)`), unless *approx_grad* is True in which case *func* returns only `f`.

args [sequence, optional] Arguments to pass to *func* and *fprime*.

approx_grad [bool, optional] Whether to approximate the gradient numerically (in which case *func* returns only the function value).

bounds [list, optional] `(min, max)` pairs for each element in `x`, defining the bounds on that parameter. Use None or +-inf for one of `min` or `max` when there is no bound in that direction.

m [int, optional] The maximum number of variable metric corrections used to define the limited memory matrix. (The limited memory BFGS method does not store the full hessian but uses this many terms in an approximation to it.)

factr [float, optional] The iteration stops when `(f^k - f^{k+1})/max{|f^k|, |f^{k+1}|,1} <= factr * eps`, where `eps` is the machine precision, which is automatically generated by the code. Typical values for *factr* are: 1e12 for low accuracy; 1e7 for moderate accuracy; 10.0 for extremely high accuracy. See Notes for relationship to *ftol*, which is exposed (instead of *factr*) by the *scipy.optimize.minimize* interface to L-BFGS-B.

pgtol [float, optional] The iteration will stop when `max{|proj g_i | i = 1, ..., n} <= pgtol` where `pg_i` is the i-th component of the projected gradient.

epsilon [float, optional] Step size used when *approx_grad* is True, for numerically calculating the gradient

iprint [int, optional] Controls the frequency of output. `iprint < 0` means no output; `iprint = 0` print only one line at the last iteration; `0 < iprint < 99` print also f and `|proj g|` every iprint iterations; `iprint = 99` print details of every iteration except n-vectors; `iprint = 100` print also the changes of active set and final x; `iprint > 100` print details of every iteration including x and g.

disp [int, optional] If zero, then no output. If a positive number, then this over-rides *iprint* (i.e., *iprint* gets the value of *disp*).

maxfun [int, optional] Maximum number of function evaluations.

maxiter [int, optional] Maximum number of iterations.

callback [callable, optional] Called after each iteration, as `callback(xk)`, where `xk` is the current parameter vector.

maxls [int, optional] Maximum number of line search steps (per iteration). Default is 20.

Returns

x [array_like] Estimated position of the minimum.
f [float] Value of *func* at the minimum.
d [dict] Information dictionary.

- d['warnflag'] is
  - 0 if converged,
  - 1 if too many function evaluations or too many iterations,
  - 2 if stopped for another reason, given in d['task']
- d['grad'] is the gradient at the minimum (should be 0 ish)
- d['funcalls'] is the number of function calls made.
- d['nit'] is the number of iterations.

See also:

`minimize`

Interface to minimization algorithms for multivariate functions. See the 'L-BFGS-B' *method* in particular. Note that the *ftol* option is made available via that interface, while *factr* is provided via this interface, where *factr* is the factor multiplying the default machine floating-point precision to arrive at *ftol*: `ftol = factr * numpy.finfo(float).eps`.

scipy.optimize.fmin_tnc

`scipy.optimize.`**`fmin_tnc`**(*func*, *x0*, *fprime=None*, *args=()*, *approx_grad=0*, *bounds=None*, *epsilon=1e-08*, *scale=None*, *offset=None*, *messages=15*, *maxCGit=- 1*, *maxfun=None*, *eta=- 1*, *stepmx=0*, *accuracy=0*, *fmin=0*, *ftol=- 1*, *xtol=- 1*, *pgtol=- 1*, *rescale=- 1*, *disp=None*, *callback=None*)

Minimize a function with variables subject to bounds, using gradient information in a truncated Newton algorithm. This method wraps a C implementation of the algorithm.

Parameters

func [callable `func(x, *args)`] Function to minimize. Must do one of:

1. Return f and g, where f is the value of the function and g its gradient (a list of floats).
2. Return the function value but supply gradient function separately as *fprime*.
3. Return the function value and set `approx_grad=True`.

If the function returns None, the minimization is aborted.

x0 [array_like] Initial estimate of minimum.

fprime [callable `fprime(x, *args)`, optional] Gradient of *func*. If None, then either *func* must return the function value and the gradient (`f,g = func(x, *args)`) or *approx_grad* must be True.

args [tuple, optional] Arguments to pass to function.

approx_grad [bool, optional] If true, approximate the gradient numerically.

bounds [list, optional] (min, max) pairs for each element in x0, defining the bounds on that parameter. Use None or +/-inf for one of min or max when there is no bound in that direction.

epsilon [float, optional] Used if approx_grad is True. The stepsize in a finite difference approximation for fprime.

scale [array_like, optional] Scaling factors to apply to each variable. If None, the factors are up-low for interval bounded variables and 1+|x| for the others. Defaults to None.

offset [array_like, optional] Value to subtract from each variable. If None, the offsets are (up+low)/2 for interval bounded variables and x for the others.

messages [int, optional] Bit mask used to select messages display during minimization values defined in the MSGS dict. Defaults to MGS_ALL.

disp [int, optional] Integer interface to messages. 0 = no message, 5 = all messages

maxCGit [int, optional] Maximum number of hessian*vector evaluations per main iteration. If maxCGit == 0, the direction chosen is -gradient if maxCGit < 0, maxCGit is set to max(1,min(50,n/2)). Defaults to -1.

maxfun [int, optional] Maximum number of function evaluation. If None, maxfun is set to max(100, 10*len(x0)). Defaults to None.

eta [float, optional] Severity of the line search. If < 0 or > 1, set to 0.25. Defaults to -1.

stepmx [float, optional] Maximum step for the line search. May be increased during call. If too small, it will be set to 10.0. Defaults to 0.

accuracy [float, optional] Relative precision for finite difference calculations. If <= machine_precision, set to sqrt(machine_precision). Defaults to 0.

fmin [float, optional] Minimum function value estimate. Defaults to 0.

ftol [float, optional] Precision goal for the value of f in the stopping criterion. If ftol < 0.0, ftol is set to 0.0 defaults to -1.

xtol [float, optional] Precision goal for the value of x in the stopping criterion (after applying x scaling factors). If xtol < 0.0, xtol is set to sqrt(machine_precision). Defaults to -1.

pgtol [float, optional] Precision goal for the value of the projected gradient in the stopping criterion (after applying x scaling factors). If pgtol < 0.0, pgtol is set to 1e-2 * sqrt(accuracy). Setting it to 0.0 is not recommended. Defaults to -1.

rescale [float, optional] Scaling factor (in log10) used to trigger f value rescaling. If 0, rescale at each iteration. If a large value, never rescale. If < 0, rescale is set to 1.3.

callback [callable, optional] Called after each iteration, as callback(xk), where xk is the current parameter vector.

Returns

x [ndarray] The solution.

nfeval [int] The number of function evaluations.

rc [int] Return code, see below

See also:

minimize

Interface to minimization algorithms for multivariate functions. See the 'TNC' *method* in particular.

Notes

The underlying algorithm is truncated Newton, also called Newton Conjugate-Gradient. This method differs from scipy.optimize.fmin_ncg in that

1. it wraps a C implementation of the algorithm
2. it allows each variable to be given an upper and lower bound.

The algorithm incorporates the bound constraints by determining the descent direction as in an unconstrained truncated Newton, but never taking a step-size large enough to leave the space of feasible x's. The algorithm keeps track of a set of currently active constraints, and ignores them when computing the minimum allowable step size. (The x's associated with the active constraint are kept fixed.) If the maximum allowable step size is zero then a new constraint is added. At the end of each iteration one of the constraints may be deemed no longer active and removed. A constraint is considered no longer active is if it is currently active but the gradient for that variable points inward from the constraint. The specific constraint removed is the one associated with the variable of largest index whose constraint is no longer active.

Return codes are defined as follows:

```
-1 : Infeasible (lower bound > upper bound)
 0 : Local minimum reached (|pg| ~= 0)
 1 : Converged (|f_n-f_(n-1)| ~= 0)
 2 : Converged (|x_n-x_(n-1)| ~= 0)
 3 : Max. number of function evaluations reached
 4 : Linear search failed
 5 : All lower bounds are equal to the upper bounds
 6 : Unable to progress
 7 : User requested end of minimization
```

scipy.optimize.fmin_cobyla

scipy.optimize.**fmin_cobyla**(*func*, *x0*, *cons*, *args=()*, *consargs=None*, *rhobeg=1.0*, *rhoend=0.0001*, *maxfun=1000*, *disp=None*, *catol=0.0002*)

Minimize a function using the Constrained Optimization By Linear Approximation (COBYLA) method. This method wraps a FORTRAN implementation of the algorithm.

Parameters

func	[callable] Function to minimize. In the form func(x, *args).
x0	[ndarray] Initial guess.
cons	[sequence] Constraint functions; must all be `>=0` (a single function if only 1 constraint). Each function takes the parameters *x* as its first argument, and it can return either a single number or an array or list of numbers.
args	[tuple, optional] Extra arguments to pass to function.
consargs	[tuple, optional] Extra arguments to pass to constraint functions (default of None means use same extra arguments as those passed to func). Use `()` for no extra arguments.
rhobeg	[float, optional] Reasonable initial changes to the variables.

rhoend [float, optional] Final accuracy in the optimization (not precisely guaranteed). This is a lower bound on the size of the trust region.
disp [{0, 1, 2, 3}, optional] Controls the frequency of output; 0 implies no output.
maxfun [int, optional] Maximum number of function evaluations.
catol [float, optional] Absolute tolerance for constraint violations.

Returns

x [ndarray] The argument that minimises *f*.

See also:

minimize

Interface to minimization algorithms for multivariate functions. See the 'COBYLA' *method* in particular.

Notes

This algorithm is based on linear approximations to the objective function and each constraint. We briefly describe the algorithm.

Suppose the function is being minimized over k variables. At the jth iteration the algorithm has k+1 points v_1, …, v_(k+1), an approximate solution x_j, and a radius RHO_j. (i.e., linear plus a constant) approximations to the objective function and constraint functions such that their function values agree with the linear approximation on the k+1 points v_1,.., v_(k+1). This gives a linear program to solve (where the linear approximations of the constraint functions are constrained to be non-negative).

However, the linear approximations are likely only good approximations near the current simplex, so the linear program is given the further requirement that the solution, which will become x_(j+1), must be within RHO_j from x_j. RHO_j only decreases, never increases. The initial RHO_j is rhobeg and the final RHO_j is rhoend. In this way COBYLA's iterations behave like a trust region algorithm.

Additionally, the linear program may be inconsistent, or the approximation may give poor improvement. For details about how these issues are resolved, as well as how the points v_i are updated, refer to the source code or the references below.

Examples

Minimize the objective function f(x,y) = x*y subject to the constraints x**2 + y**2 < 1 and y > 0:

```
>>> def objective(x):
...     return x[0]*x[1]
...
>>> def constr1(x):
...     return 1 - (x[0]**2 + x[1]**2)
...
>>> def constr2(x):
...     return x[1]
...
>>> from scipy.optimize import fmin_cobyla
>>> fmin_cobyla(objective, [0.0, 0.1], [constr1, constr2], rhoend=1e-7)
array([-0.70710685,  0.70710671])
```

The exact solution is (-sqrt(2)/2, sqrt(2)/2).

scipy.optimize.fmin_slsqp

scipy.optimize.**fmin_slsqp**(*func*, *x0*, *eqcons=()*, *f_eqcons=None*, *ieqcons=()*, *f_ieqcons=None*, *bounds=()*, *fprime=None*, *fprime_eqcons=None*, *fprime_ieqcons=None*, *args=()*, *iter=100*, *acc=1e-06*, *iprint=1*, *disp=None*, *full_output=0*, *epsilon=1.4901161193847656e-08*, *callback=None*)

Minimize a function using Sequential Least Squares Programming

Python interface function for the SLSQP Optimization subroutine originally implemented by Dieter Kraft.

Parameters

func [callable f(x,*args)] Objective function. Must return a scalar.

x0 [1-D ndarray of float] Initial guess for the independent variable(s).

eqcons [list, optional] A list of functions of length n such that eqcons[j](x,*args) == 0.0 in a successfully optimized problem.

f_eqcons [callable f(x,*args), optional] Returns a 1-D array in which each element must equal 0.0 in a successfully optimized problem. If f_eqcons is specified, eqcons is ignored.

ieqcons [list, optional] A list of functions of length n such that ieqcons[j](x,*args) >= 0.0 in a successfully optimized problem.

f_ieqcons [callable f(x,*args), optional] Returns a 1-D ndarray in which each element must be greater or equal to 0.0 in a successfully optimized problem. If f_ieqcons is specified, ieqcons is ignored.

bounds [list, optional] A list of tuples specifying the lower and upper bound for each independent variable [(xl0, xu0),(xl1, xu1),…] Infinite values will be interpreted as large floating values.

fprime [callable *f(x,*args)*, optional] A function that evaluates the partial derivatives of func.

fprime_eqcons [callable *f(x,*args)*, optional] A function of the form *f(x, *args)* that returns the m by n array of equality constraint normals. If not provided, the normals will be approximated. The array returned by fprime_eqcons should be sized as (len(eqcons), len(x0)).

fprime_ieqcons [callable *f(x,*args)*, optional] A function of the form *f(x, *args)* that returns the m by n array of inequality constraint normals. If not provided, the normals will be approximated. The array returned by fprime_ieqcons should be sized as (len(ieqcons), len(x0)).

args [sequence, optional] Additional arguments passed to func and fprime.

iter [int, optional] The maximum number of iterations.

acc [float, optional] Requested accuracy.
iprint [int, optional] The verbosity of fmin_slsqp :
- iprint <= 0 : Silent operation
- iprint == 1 : Print summary upon completion (default)
- iprint >= 2 : Print status of each iterate and summary

disp [int, optional] Overrides the iprint interface (preferred).
full_output [bool, optional] If False, return only the minimizer of func (default). Otherwise, output final objective function and summary information.
epsilon [float, optional] The step size for finite-difference derivative estimates.
callback [callable, optional] Called after each iteration, as `callback(x)`, where `x` is the current parameter vector.

Returns

out [ndarray of float] The final minimizer of func.
fx [ndarray of float, if full_output is true] The final value of the objective function.
its [int, if full_output is true] The number of iterations.
imode [int, if full_output is true] The exit mode from the optimizer (see below).
smode [string, if full_output is true] Message describing the exit mode from the optimizer.

See also:

`minimize`

Interface to minimization algorithms for multivariate functions. See the 'SLSQP' *method* in particular.

Notes

Exit modes are defined as follows

```
-1 : Gradient evaluation required (g & a)
 0 : Optimization terminated successfully
 1 : Function evaluation required (f & c)
 2 : More equality constraints than independent variables
 3 : More than 3*n iterations in LSQ subproblem
 4 : Inequality constraints incompatible
 5 : Singular matrix E in LSQ subproblem
 6 : Singular matrix C in LSQ subproblem
 7 : Rank-deficient equality constraint subproblem HFTI
 8 : Positive directional derivative for linesearch
 9 : Iteration limit reached
```

Examples

Examples are given *in the tutorial*.

Univariate (scalar) minimization methods:

fminbound(func, x1, x2[, args, xtol, …])	Bounded minimization for scalar functions.
brent(func[, args, brack, tol, full_output, …])	Given a function of one variable and a possible bracket, return the local minimum of the function isolated to a fractional precision of tol.

continues on next page

Table 147 – continued from previous page

golden(func[, args, brack, tol, …])	Return the minimum of a function of one variable using golden section method.

scipy.optimize.fminbound

scipy.optimize.**fminbound**(*func*, *x1*, *x2*, *args=()*, *xtol=1e-05*, *maxfun=500*, *full_output=0*, *disp=1*)

Bounded minimization for scalar functions.

Parameters

func [callable f(x,*args)] Objective function to be minimized (must accept and return scalars).
x1, x2 [float or array scalar] The optimization bounds.
args [tuple, optional] Extra arguments passed to function.
xtol [float, optional] The convergence tolerance.
maxfun [int, optional] Maximum number of function evaluations allowed.
full_output [bool, optional] If True, return optional outputs.
disp [int, optional] **If non-zero, print messages.** 0 : no message printing. 1 : non-convergence notification messages only. 2 : print a message on convergence too. 3 : print iteration results.

Returns

xopt [ndarray] Parameters (over given interval) which minimize the objective function.
fval [number] The function value at the minimum point.
ierr [int] An error flag (0 if converged, 1 if maximum number of function calls reached).
numfunc [int] The number of function calls made.

See also:

minimize_scalar

Interface to minimization algorithms for scalar univariate functions. See the 'Bounded' *method* in particular.

Notes

Finds a local minimizer of the scalar function *func* in the interval x1 < xopt < x2 using Brent's method. (See *brent* for auto-bracketing.)

Examples

fminbound finds the minimum of the function in the given range. The following examples illustrate the same

```
>>> def f(x):
...     return x**2
```

```
>>> from scipy import optimize
```

```
>>> minimum = optimize.fminbound(f, -1, 2)
>>> minimum
0.0
>>> minimum = optimize.fminbound(f, 1, 2)
>>> minimum
1.0000059608609866
```

scipy.optimize.brent

scipy.optimize.**brent**(*func*, *args=()*, *brack=None*, *tol=1.48e-08*, *full_output=0*, *maxiter=500*)

Given a function of one variable and a possible bracket, return the local minimum of the function isolated to a fractional precision of tol.

Parameters

func	[callable f(x,*args)] Objective function.
args	[tuple, optional] Additional arguments (if present).
brack	[tuple, optional] Either a triple (xa,xb,xc) where xa<xb<xc and func(xb) < func(xa), func(xc) or a pair (xa,xb) which are used as a starting interval for a downhill bracket search (see *bracket*). Providing the pair (xa,xb) does not always mean the obtained solution will satisfy xa<=x<=xb.
tol	[float, optional] Stop if between iteration change is less than *tol*.
full_output	[bool, optional] If True, return all output args (xmin, fval, iter, funcalls).
maxiter	[int, optional] Maximum number of iterations in solution.

Returns

xmin	[ndarray] Optimum point.
fval	[float] Optimum value.
iter	[int] Number of iterations.
funcalls	[int] Number of objective function evaluations made.

See also:

minimize_scalar

Interface to minimization algorithms for scalar univariate functions. See the 'Brent' *method* in particular.

Notes

Uses inverse parabolic interpolation when possible to speed up convergence of golden section method.

Does not ensure that the minimum lies in the range specified by *brack*. See *fminbound*.

Examples

We illustrate the behaviour of the function when *brack* is of size 2 and 3 respectively. In the case where *brack* is of the form (xa,xb), we can see for the given values, the output need not necessarily lie in the range (xa,xb).

```
>>> def f(x):
...     return x**2
```

```
>>> from scipy import optimize
```

```
>>> minimum = optimize.brent(f,brack=(1,2))
>>> minimum
0.0
>>> minimum = optimize.brent(f,brack=(-1,0.5,2))
>>> minimum
-2.7755575615628914e-17
```

scipy.optimize.golden

scipy.optimize.**golden**(*func*, *args=()*, *brack=None*, *tol=1.4901161193847656e-08*, *full_output=0*, *maxiter=5000*)

Return the minimum of a function of one variable using golden section method.

Given a function of one variable and a possible bracketing interval, return the minimum of the function isolated to a fractional precision of tol.

Parameters

func	[callable func(x,*args)] Objective function to minimize.
args	[tuple, optional] Additional arguments (if present), passed to func.
brack	[tuple, optional] Triple (a,b,c), where (a<b<c) and func(b) < func(a),func(c). If bracket consists of two numbers (a, c), then they are assumed to be a starting interval for a downhill bracket search (see *bracket*); it doesn't always mean that obtained solution will satisfy a<=x<=c.
tol	[float, optional] x tolerance stop criterion
full_output	[bool, optional] If True, return optional outputs.
maxiter	[int] Maximum number of iterations to perform.

See also:

minimize_scalar

Interface to minimization algorithms for scalar univariate functions. See the 'Golden' *method* in particular.

Notes

Uses analog of bisection method to decrease the bracketed interval.

Examples

We illustrate the behaviour of the function when *brack* is of size 2 and 3, respectively. In the case where *brack* is of the form (xa,xb), we can see for the given values, the output need not necessarily lie in the range `(xa, xb)`.

```
>>> def f(x):
...     return x**2
```

```
>>> from scipy import optimize
```

```
>>> minimum = optimize.golden(f, brack=(1, 2))
>>> minimum
1.5717277788484873e-162
>>> minimum = optimize.golden(f, brack=(-1, 0.5, 2))
>>> minimum
-1.5717277788484873e-162
```

Least-squares

leastsq(func, x0[, args, Dfun, full_output, …])	Minimize the sum of squares of a set of equations.

scipy.optimize.leastsq

scipy.optimize.**leastsq**(*func*, *x0*, *args=()*, *Dfun=None*, *full_output=0*, *col_deriv=0*, *ftol=1.49012e-08*, *xtol=1.49012e-08*, *gtol=0.0*, *maxfev=0*, *epsfcn=None*, *factor=100*, *diag=None*)

Minimize the sum of squares of a set of equations.

```
x = arg min(sum(func(y)**2,axis=0))
         y
```

Parameters

func [callable] Should take at least one (possibly length `N` vector) argument and returns `M` floating point numbers. It must not return NaNs or fitting might fail. `M` must be greater than or equal to `N`.

x0 [ndarray] The starting estimate for the minimization.

args [tuple, optional] Any extra arguments to func are placed in this tuple.

Dfun [callable, optional] A function or method to compute the Jacobian of func with derivatives across the rows. If this is None, the Jacobian will be estimated.

full_output [bool, optional] non-zero to return all optional outputs.

col_deriv [bool, optional] non-zero to specify that the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).

ftol [float, optional] Relative error desired in the sum of squares.

xtol [float, optional] Relative error desired in the approximate solution.

gtol [float, optional] Orthogonality desired between the function vector and the columns of the Jacobian.

maxfev [int, optional] The maximum number of calls to the function. If *Dfun* is provided, then the default *maxfev* is 100*(N+1) where N is the number of elements in x0, otherwise the default *maxfev* is 200*(N+1).

epsfcn [float, optional] A variable used in determining a suitable step length for the forward- difference approximation of the Jacobian (for Dfun=None). Normally the actual step length will be sqrt(epsfcn)*x If epsfcn is less than the machine precision, it is assumed that the relative errors are of the order of the machine precision.

factor [float, optional] A parameter determining the initial step bound (`factor * || diag * x||`). Should be in interval `(0.1, 100)`.

diag [sequence, optional] N positive entries that serve as a scale factors for the variables.

Returns

x [ndarray] The solution (or the result of the last iteration for an unsuccessful call).

cov_x [ndarray] The inverse of the Hessian. *fjac* and *ipvt* are used to construct an estimate of the Hessian. A value of None indicates a singular matrix, which means the curvature in parameters *x* is numerically flat. To obtain the covariance matrix of the parameters *x*, *cov_x* must be multiplied by the variance of the residuals – see curve_fit.

infodict [dict] a dictionary of optional outputs with the keys:

- **`nfev`** The number of function calls
- **`fvec`** The function evaluated at the output
- **`fjac`** A permutation of the R matrix of a QR factorization of the final approximate Jacobian matrix, stored column wise. Together with ipvt, the covariance of the estimate can be approximated.
- **`ipvt`** An integer array of length N which defines a permutation matrix, p, such that fjac*p = q*r, where r is upper triangular with diagonal elements of nonincreasing magnitude. Column j of p is column ipvt(j) of the identity matrix.
- **`qtf`** The vector (transpose(q) * fvec).

mesg [str] A string message giving information about the cause of failure.

ier [int] An integer flag. If it is equal to 1, 2, 3 or 4, the solution was found. Otherwise, the solution was not found. In either case, the optional output variable 'mesg' gives more information.

See also:

`least_squares`

Newer interface to solve nonlinear least-squares problems with bounds on the variables. See `method=='lm'` in particular.

Notes

"leastsq" is a wrapper around MINPACK's lmdif and lmder algorithms.

cov_x is a Jacobian approximation to the Hessian of the least squares objective function. This approximation assumes that the objective function is based on the difference between some observed target data (ydata) and a (non-linear) function of the parameters *f(xdata, params)*

```
func(params) = ydata - f(xdata, params)
```

so that the objective function is

```
  min   sum((ydata - f(xdata, params))**2, axis=0)
params
```

The solution, *x*, is always a 1-D array, regardless of the shape of *x0*, or whether *x0* is a scalar.

Examples

```
>>> from scipy.optimize import leastsq
>>> def func(x):
...     return 2*(x-3)**2+1
>>> leastsq(func, 0)
(array([2.99999999]), 1)
```

Root finding

General nonlinear solvers:

fsolve(func, x0[, args, fprime, …])	Find the roots of a function.
broyden1(F, xin[, iter, alpha, …])	Find a root of a function, using Broyden's first Jacobian approximation.
broyden2(F, xin[, iter, alpha, …])	Find a root of a function, using Broyden's second Jacobian approximation.

scipy.optimize.fsolve

scipy.optimize.**fsolve**(*func*, *x0*, *args=()*, *fprime=None*, *full_output=0*, *col_deriv=0*, *xtol=1.49012e-08*, *maxfev=0*, *band=None*, *epsfcn=None*, *factor=100*, *diag=None*)

Find the roots of a function.

Return the roots of the (non-linear) equations defined by `func(x) = 0` given a starting estimate.

Parameters

func [callable `f(x, *args)`] A function that takes at least one (possibly vector) argument, and returns a value of the same length.

x0 [ndarray] The starting estimate for the roots of `func(x) = 0`.

args [tuple, optional] Any extra arguments to *func*.

fprime [callable `f(x, *args)`, optional] A function to compute the Jacobian of *func* with derivatives across the rows. By default, the Jacobian will be estimated.

full_output [bool, optional] If True, return optional outputs.

col_deriv [bool, optional] Specify whether the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).

xtol [float, optional] The calculation will terminate if the relative error between two consecutive iterates is at most *xtol*.

maxfev [int, optional] The maximum number of calls to the function. If zero, then `100*(N+1)` is the maximum where N is the number of elements in *x0*.

band [tuple, optional] If set to a two-sequence containing the number of sub- and super-diagonals within the band of the Jacobi matrix, the Jacobi matrix is considered banded (only for `fprime=None`).

epsfcn [float, optional] A suitable step length for the forward-difference approximation of the Jacobian (for `fprime=None`). If *epsfcn* is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision.

factor [float, optional] A parameter determining the initial step bound (`factor * || diag * x||`). Should be in the interval `(0.1, 100)`.

diag [sequence, optional] N positive entries that serve as a scale factors for the variables.

Returns

x [ndarray] The solution (or the result of the last iteration for an unsuccessful call).

infodict [dict] A dictionary of optional outputs with the keys:

- **nfev** number of function calls
- **njev** number of Jacobian calls
- **fvec** function evaluated at the output
- **fjac** the orthogonal matrix, q, produced by the QR factorization of the final approximate Jacobian matrix, stored column wise
- **r** upper triangular matrix produced by QR factorization of the same matrix
- **qtf** the vector `(transpose(q) * fvec)`

ier [int] An integer flag. Set to 1 if a solution was found, otherwise refer to *mesg* for more information.

mesg [str] If no solution is found, *mesg* details the cause of failure.

See also:

`root`

Interface to root finding algorithms for multivariate functions. See the `method=='hybr'` in particular.

Notes

`fsolve` is a wrapper around MINPACK's hybrd and hybrj algorithms.

Examples

Find a solution to the system of equations: `x0*cos(x1) = 4, x1*x0 - x1 = 5`.

```
>>> from scipy.optimize import fsolve
>>> def func(x):
...     return [x[0] * np.cos(x[1]) - 4,
...             x[1] * x[0] - x[1] - 5]
>>> root = fsolve(func, [1, 1])
>>> root
array([6.50409711, 0.90841421])
>>> np.isclose(func(root), [0.0, 0.0])  # func(root) should be almost 0.0.
array([ True,  True])
```

scipy.optimize.broyden1

scipy.optimize.**broyden1**(*F*, *xin*, *iter=None*, *alpha=None*, *reduction_method='restart'*, *max_rank=None*, *verbose=False*, *maxiter=None*, *f_tol=None*, *f_rtol=None*, *x_tol=None*, *x_rtol=None*, *tol_norm=None*, *line_search='armijo'*, *callback=None*, ***kw*)

Find a root of a function, using Broyden's first Jacobian approximation.

This method is also known as "Broyden's good method".

Parameters

F [function(x) -> f] Function whose root to find; should take and return an array-like object.

xin [array_like] Initial guess for the solution

alpha [float, optional] Initial guess for the Jacobian is `(-1/alpha)`.

reduction_method

[str or tuple, optional] Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form `(method, param1, param2, ...)` that gives the name of the method and values for additional parameters.

Methods available:

- `restart`: drop all matrix columns. Has no extra parameters.
- `simple`: drop oldest matrix column. Has no extra parameters.
- `svd`: keep only the most significant SVD components. Takes an extra parameter, `to_retain`, which determines the number of SVD components to retain when rank reduction is done. Default is `max_rank - 2`.

max_rank [int, optional] Maximum rank for the Broyden matrix. Default is infinity (i.e., no rank reduction).

iter [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

verbose [bool, optional] Print status to stdout on every iteration.

maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.

f_tol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

f_rtol [float, optional] Relative tolerance for the residual. If omitted, not used.

x_tol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

x_rtol [float, optional] Relative minimum step size. If omitted, not used.

tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search

[{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

callback [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where *x* is the current solution and *f* the corresponding residual.

Returns

sol [ndarray] An array (of similar array type as *x0*) containing the final solution.

Raises

NoConvergence

When a solution was not found.

See also:

root

Interface to root finding algorithms for multivariate functions. See `method=='broyden1'` in particular.

Notes

This algorithm implements the inverse Jacobian Quasi-Newton update

$$H_+ = H + (dx - Hdf)dx^\dagger H/(dx^\dagger Hdf)$$

which corresponds to Broyden's first Jacobian update

$$J_+ = J + (df - Jdx)dx^\dagger/dx^\dagger dx$$

References

[1]

Examples

The following functions define a system of nonlinear equations

```
>>> def fun(x):
...     return [x[0]  + 0.5 * (x[0] - x[1])**3 - 1.0,
...             0.5 * (x[1] - x[0])**3 + x[1]]
```

A solution can be obtained as follows.

```
>>> from scipy import optimize
>>> sol = optimize.broyden1(fun, [0, 0])
>>> sol
array([0.84116396, 0.15883641])
```

scipy.optimize.broyden2

scipy.optimize.**broyden2**(*F*, *xin*, *iter=None*, *alpha=None*, *reduction_method='restart'*, *max_rank=None*, *verbose=False*, *maxiter=None*, *f_tol=None*, *f_rtol=None*, *x_tol=None*, *x_rtol=None*, *tol_norm=None*, *line_search='armijo'*, *callback=None*, ***kw*)

Find a root of a function, using Broyden's second Jacobian approximation.

This method is also known as "Broyden's bad method".

Parameters

F [function(x) -> f] Function whose root to find; should take and return an array-like object.

xin [array_like] Initial guess for the solution

alpha [float, optional] Initial guess for the Jacobian is `(-1/alpha)`.

reduction_method

[str or tuple, optional] Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form `(method, param1, param2, ...)` that gives the name of the method and values for additional parameters.
Methods available:

- `restart`: drop all matrix columns. Has no extra parameters.
- `simple`: drop oldest matrix column. Has no extra parameters.
- `svd`: keep only the most significant SVD components. Takes an extra parameter, `to_retain`, which determines the number of SVD components to retain when rank reduction is done. Default is `max_rank - 2`.

max_rank [int, optional] Maximum rank for the Broyden matrix. Default is infinity (i.e., no rank reduction).

iter [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

verbose [bool, optional] Print status to stdout on every iteration.

maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.

f_tol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

f_rtol [float, optional] Relative tolerance for the residual. If omitted, not used.

x_tol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

x_rtol [float, optional] Relative minimum step size. If omitted, not used.

tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search [{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

callback [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where *x* is the current solution and *f* the corresponding residual.

Returns

sol [ndarray] An array (of similar array type as *x0*) containing the final solution.

Raises

NoConvergence When a solution was not found.

See also:

root

Interface to root finding algorithms for multivariate functions. See `method=='broyden2'` in particular.

Notes

This algorithm implements the inverse Jacobian Quasi-Newton update

$$H_+ = H + (dx - Hdf)df^\dagger/(df^\dagger df)$$

corresponding to Broyden's second method.

Examples

The following functions define a system of nonlinear equations

```
>>> def fun(x):
...     return [x[0]  + 0.5 * (x[0] - x[1])**3 - 1.0,
...             0.5 * (x[1] - x[0])**3 + x[1]]
```

A solution can be obtained as follows.

```
>>> from scipy import optimize
>>> sol = optimize.broyden2(fun, [0, 0])
>>> sol
array([0.84116365, 0.15883529])
```

Large-scale nonlinear solvers:

newton_krylov(F, xin[, iter, rdiff, method, …])	Find a root of a function, using Krylov approximation for inverse Jacobian.
anderson(F, xin[, iter, alpha, w0, M, …])	Find a root of a function, using (extended) Anderson mixing.

scipy.optimize.newton_krylov

scipy.optimize.**newton_krylov**(*F*, *xin*, *iter=None*, *rdiff=None*, *method='lgmres'*, *inner_maxiter=20*, *inner_M=None*, *outer_k=10*, *verbose=False*, *maxiter=None*, *f_tol=None*, *f_rtol=None*, *x_tol=None*, *x_rtol=None*, *tol_norm=None*, *line_search='armijo'*, *callback=None*, ***kw*)

Find a root of a function, using Krylov approximation for inverse Jacobian.

This method is suitable for solving large-scale problems.

Parameters

F [function(x) -> f] Function whose root to find; should take and return an array-like object.

xin [array_like] Initial guess for the solution

rdiff [float, optional] Relative step size to use in numerical differentiation.

method [{'lgmres', 'gmres', 'bicgstab', 'cgs', 'minres'} or function] Krylov method to use to approximate the Jacobian. Can be a string, or a function implementing the same interface as the iterative solvers in *scipy.sparse.linalg*.
The default is *scipy.sparse.linalg.lgmres*.

inner_maxiter
[int, optional] Parameter to pass to the "inner" Krylov solver: maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

inner_M [LinearOperator or InverseJacobian] Preconditioner for the inner Krylov iteration. Note that you can use also inverse Jacobians as (adaptive) preconditioners. For example,

```
>>> from scipy.optimize.nonlin import BroydenFirst,␣
↪KrylovJacobian
>>> from scipy.optimize.nonlin import InverseJacobian
>>> jac = BroydenFirst()
>>> kjac = KrylovJacobian(inner_M=InverseJacobian(jac))
```

If the preconditioner has a method named 'update', it will be called as `update(x, f)` after each nonlinear step, with `x` giving the current point, and `f` the current function value.

outer_k [int, optional] Size of the subspace kept across LGMRES nonlinear iterations. See *scipy.sparse.linalg.lgmres* for details.

inner_kwargs
[kwargs] Keyword parameters for the "inner" Krylov solver (defined with *method*). Parameter names must start with the *inner_* prefix which will be stripped before passing on the inner method. See, e.g., *scipy.sparse.linalg.gmres* for details.

iter [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

verbose [bool, optional] Print status to stdout on every iteration.

maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.

f_tol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

f_rtol [float, optional] Relative tolerance for the residual. If omitted, not used.

x_tol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

x_rtol [float, optional] Relative minimum step size. If omitted, not used.

tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search
[{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

callback [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where *x* is the current solution and *f* the corresponding residual.

Returns

sol [ndarray] An array (of similar array type as *x0*) containing the final solution.

Raises

NoConvergence
When a solution was not found.

root

Interface to root finding algorithms for multivariate functions. See `method=='krylov'` in particular.

scipy.sparse.linalg.gmres

scipy.sparse.linalg.lgmres

Notes

This function implements a Newton-Krylov solver. The basic idea is to compute the inverse of the Jacobian with an iterative Krylov method. These methods require only evaluating the Jacobian-vector products, which are conveniently approximated by a finite difference:

$$Jv \approx (f(x + \omega * v/|v|) - f(x))/\omega$$

Due to the use of iterative matrix inverses, these methods can deal with large nonlinear problems.

SciPy's *scipy.sparse.linalg* module offers a selection of Krylov solvers to choose from. The default here is *lgmres*, which is a variant of restarted GMRES iteration that reuses some of the information obtained in the previous Newton steps to invert Jacobians in subsequent steps.

For a review on Newton-Krylov methods, see for example [1], and for the LGMRES sparse inverse method, see [2].

References

[1], [2]

Examples

The following functions define a system of nonlinear equations

```
>>> def fun(x):
...     return [x[0] + 0.5 * x[1] - 1.0,
...             0.5 * (x[1] - x[0]) ** 2]
```

A solution can be obtained as follows.

```
>>> from scipy import optimize
>>> sol = optimize.newton_krylov(fun, [0, 0])
>>> sol
array([0.66731771, 0.66536458])
```

scipy.optimize.anderson

scipy.optimize.**anderson**(*F*, *xin*, *iter=None*, *alpha=None*, *w0=0.01*, *M=5*, *verbose=False*, *maxiter=None*, *f_tol=None*, *f_rtol=None*, *x_tol=None*, *x_rtol=None*, *tol_norm=None*, *line_search='armijo'*, *callback=None*, ***kw*)

Find a root of a function, using (extended) Anderson mixing.

The Jacobian is formed by for a 'best' solution in the space spanned by last *M* vectors. As a result, only a MxM matrix inversions and MxN multiplications are required. [Ey]

Parameters

F	[function(x) -> f] Function whose root to find; should take and return an array-like object.
xin	[array_like] Initial guess for the solution
alpha	[float, optional] Initial guess for the Jacobian is (-1/alpha).
M	[float, optional] Number of previous vectors to retain. Defaults to 5.
w0	[float, optional] Regularization parameter for numerical stability. Compared to unity, good values of the order of 0.01.

iter [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

verbose [bool, optional] Print status to stdout on every iteration.

maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.

f_tol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

f_rtol [float, optional] Relative tolerance for the residual. If omitted, not used.

x_tol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

x_rtol [float, optional] Relative minimum step size. If omitted, not used.

tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search [{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

callback [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where *x* is the current solution and *f* the corresponding residual.

Returns

sol [ndarray] An array (of similar array type as *x0*) containing the final solution.

Raises

NoConvergence
When a solution was not found.

[Ey]

Examples

The following functions define a system of nonlinear equations

```
>>> def fun(x):
...     return [x[0]  + 0.5 * (x[0] - x[1])**3 - 1.0,
...             0.5 * (x[1] - x[0])**3 + x[1]]
```

A solution can be obtained as follows.

```
>>> from scipy import optimize
>>> sol = optimize.anderson(fun, [0, 0])
>>> sol
array([0.84116588, 0.15883789])
```

Simple iteration solvers:

excitingmixing(F, xin[, iter, alpha, …])	Find a root of a function, using a tuned diagonal Jacobian approximation.
linearmixing(F, xin[, iter, alpha, verbose, …])	Find a root of a function, using a scalar Jacobian approximation.
diagbroyden(F, xin[, iter, alpha, verbose, …])	Find a root of a function, using diagonal Broyden Jacobian approximation.

scipy.optimize.excitingmixing

scipy.optimize.**excitingmixing**(*F*, *xin*, *iter=None*, *alpha=None*, *alphamax=1.0*, *verbose=False*, *maxiter=None*, *f_tol=None*, *f_rtol=None*, *x_tol=None*, *x_rtol=None*, *tol_norm=None*, *line_search='armijo'*, *callback=None*, ***kw*)

Find a root of a function, using a tuned diagonal Jacobian approximation.

The Jacobian matrix is diagonal and is tuned on each iteration.

Warning: This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.

Parameters

F [function(x) -> f] Function whose root to find; should take and return an array-like object.
xin [array_like] Initial guess for the solution
alpha [float, optional] Initial Jacobian approximation is (-1/alpha).
alphamax [float, optional] The entries of the diagonal Jacobian are kept in the range `[alpha, alphamax]`.
iter [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
verbose [bool, optional] Print status to stdout on every iteration.
maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.
f_tol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
f_rtol [float, optional] Relative tolerance for the residual. If omitted, not used.
x_tol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
x_rtol [float, optional] Relative minimum step size. If omitted, not used.
tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
line_search [{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.
callback [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where *x* is the current solution and *f* the corresponding residual.

Returns

sol [ndarray] An array (of similar array type as *x0*) containing the final solution.

Raises

NoConvergence
When a solution was not found.

See also:

`root`

Interface to root finding algorithms for multivariate functions. See `method=='excitingmixing'` in particular.

scipy.optimize.linearmixing

`scipy.optimize.linearmixing(F, xin, iter=None, alpha=None, verbose=False, maxiter=None, f_tol=None, f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None, line_search='armijo', callback=None, **kw)`

Find a root of a function, using a scalar Jacobian approximation.

Warning: This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.

Parameters

F [function(x) -> f] Function whose root to find; should take and return an array-like object.
xin [array_like] Initial guess for the solution
alpha [float, optional] The Jacobian approximation is (-1/alpha).
iter [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
verbose [bool, optional] Print status to stdout on every iteration.
maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.
f_tol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
f_rtol [float, optional] Relative tolerance for the residual. If omitted, not used.
x_tol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
x_rtol [float, optional] Relative minimum step size. If omitted, not used.
tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.
line_search [{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.
callback [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where *x* is the current solution and *f* the corresponding residual.

Returns

sol [ndarray] An array (of similar array type as *x0*) containing the final solution.

Raises

NoConvergence
When a solution was not found.

See also:

`root`

Interface to root finding algorithms for multivariate functions. See `method=='linearmixing'` in particular.

scipy.optimize.diagbroyden

scipy.optimize.**diagbroyden**(*F*, *xin*, *iter=None*, *alpha=None*, *verbose=False*, *maxiter=None*, *f_tol=None*, *f_rtol=None*, *x_tol=None*, *x_rtol=None*, *tol_norm=None*, *line_search='armijo'*, *callback=None*, ***kw*)

Find a root of a function, using diagonal Broyden Jacobian approximation.

The Jacobian approximation is derived from previous iterations, by retaining only the diagonal of Broyden matrices.

Warning: This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.

Parameters

F [function(x) -> f] Function whose root to find; should take and return an array-like object.

xin [array_like] Initial guess for the solution

alpha [float, optional] Initial guess for the Jacobian is (-1/alpha).

iter [int, optional] Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

verbose [bool, optional] Print status to stdout on every iteration.

maxiter [int, optional] Maximum number of iterations to make. If more are needed to meet convergence, *NoConvergence* is raised.

f_tol [float, optional] Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

f_rtol [float, optional] Relative tolerance for the residual. If omitted, not used.

x_tol [float, optional] Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

x_rtol [float, optional] Relative minimum step size. If omitted, not used.

tol_norm [function(vector) -> scalar, optional] Norm to use in convergence check. Default is the maximum norm.

line_search [{None, 'armijo' (default), 'wolfe'}, optional] Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to 'armijo'.

callback [function, optional] Optional callback function. It is called on every iteration as `callback(x, f)` where *x* is the current solution and *f* the corresponding residual.

Returns

sol [ndarray] An array (of similar array type as *x0*) containing the final solution.

Raises

NoConvergence When a solution was not found.

See also:

root

Interface to root finding algorithms for multivariate functions. See `method=='diagbroyden'` in particular.

Examples

The following functions define a system of nonlinear equations

```
>>> def fun(x):
...     return [x[0]  + 0.5 * (x[0] - x[1])**3 - 1.0,
...             0.5 * (x[1] - x[0])**3 + x[1]]
```

A solution can be obtained as follows.

```
>>> from scipy import optimize
>>> sol = optimize.diagbroyden(fun, [0, 0])
>>> sol
array([0.84116403, 0.15883384])
```

Additional information on the nonlinear solvers

3.3.20 Nonlinear solvers

This is a collection of general-purpose nonlinear multidimensional solvers. These solvers find *x* for which *F(x) = 0*. Both *x* and *F* can be multidimensional.

Routines

Large-scale nonlinear solvers:

newton_krylov(F, xin[, iter, rdiff, method, …])	Find a root of a function, using Krylov approximation for inverse Jacobian.
anderson(F, xin[, iter, alpha, w0, M, …])	Find a root of a function, using (extended) Anderson mixing.

General nonlinear solvers:

broyden1(F, xin[, iter, alpha, …])	Find a root of a function, using Broyden's first Jacobian approximation.
broyden2(F, xin[, iter, alpha, …])	Find a root of a function, using Broyden's second Jacobian approximation.

Simple iterations:

excitingmixing(F, xin[, iter, alpha, …])	Find a root of a function, using a tuned diagonal Jacobian approximation.
linearmixing(F, xin[, iter, alpha, verbose, …])	Find a root of a function, using a scalar Jacobian approximation.

continues on next page

Table 154 – continued from previous page

diagbroyden(F, xin[, iter, alpha, verbose, …])	Find a root of a function, using diagonal Broyden Jacobian approximation.

Examples

Small problem

```
>>> def F(x):
...     return np.cos(x) + x[::-1] - [1, 2, 3, 4]
>>> import scipy.optimize
>>> x = scipy.optimize.broyden1(F, [1,1,1,1], f_tol=1e-14)
>>> x
array([ 4.04674914,  3.91158389,  2.71791677,  1.61756251])
>>> np.cos(x) + x[::-1]
array([ 1.,  2.,  3.,  4.])
```

Large problem

Suppose that we needed to solve the following integrodifferential equation on the square $[0,1] \times [0,1]$:

$$\nabla^2 P = 10 \left(\int_0^1 \int_0^1 \cosh(P)\, dx\, dy \right)^2$$

with $P(x,1) = 1$ and $P = 0$ elsewhere on the boundary of the square.

The solution can be found using the *newton_krylov* solver:

```
import numpy as np
from scipy.optimize import newton_krylov
from numpy import cosh, zeros_like, mgrid, zeros

# parameters
nx, ny = 75, 75
hx, hy = 1./(nx-1), 1./(ny-1)

P_left, P_right = 0, 0
P_top, P_bottom = 1, 0

def residual(P):
    d2x = zeros_like(P)
    d2y = zeros_like(P)

    d2x[1:-1] = (P[2:]   - 2*P[1:-1] + P[:-2]) / hx/hx
    d2x[0]    = (P[1]    - 2*P[0]    + P_left)/hx/hx
    d2x[-1]   = (P_right - 2*P[-1]   + P[-2])/hx/hx

    d2y[:,1:-1] = (P[:,2:] - 2*P[:,1:-1] + P[:,:-2])/hy/hy
    d2y[:,0]    = (P[:,1]  - 2*P[:,0]    + P_bottom)/hy/hy
    d2y[:,-1]   = (P_top   - 2*P[:,-1]   + P[:,-2])/hy/hy

    return d2x + d2y - 10*cosh(P).mean()**2

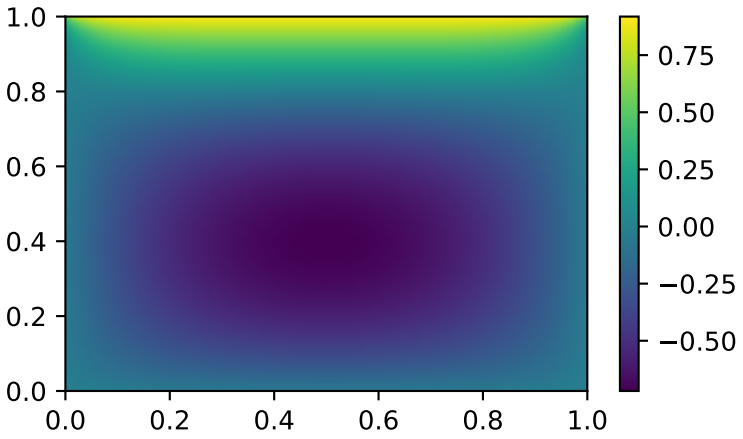
# solve
```

(continues on next page)

(continued from previous page)

```
guess = zeros((nx, ny), float)
sol = newton_krylov(residual, guess, method='lgmres', verbose=1)
print('Residual: %g' % abs(residual(sol)).max())

# visualize
import matplotlib.pyplot as plt
x, y = mgrid[0:1:(nx*1j), 0:1:(ny*1j)]
plt.pcolormesh(x, y, sol, shading='gouraud')
plt.colorbar()
plt.show()
```



3.3.21 Cython optimize zeros API

The underlying C functions for the following root finders can be accessed directly using Cython:

- *bisect*
- *ridder*
- *brenth*
- *brentq*

The Cython API for the zeros functions is similar except there is no `disp` argument. Import the zeros functions using `cimport` from *scipy.optimize.cython_optimize*.

```
from scipy.optimize.cython_optimize cimport bisect, ridder, brentq, brenth
```

Callback signature

The zeros functions in *cython_optimize* expect a callback that takes a double for the scalar independent variable as the 1st argument and a user defined `struct` with any extra parameters as the 2nd argument.

```
double (*callback_type)(double, void*)
```

Examples

Usage of *cython_optimize* requires Cython to write callbacks that are compiled into C. For more information on compiling Cython, see the Cython Documentation.

These are the basic steps:

1. Create a Cython `.pyx` file, for example: `myexample.pyx`.
2. Import the desired root finder from *cython_optimize*.
3. Write the callback function, and call the selected zeros function passing the callback, any extra arguments, and the other solver parameters.

```
from scipy.optimize.cython_optimize cimport brentq

# import math from Cython
from libc cimport math

myargs = {'C0': 1.0, 'C1': 0.7}  # a dictionary of extra arguments
XLO, XHI = 0.5, 1.0  # lower and upper search boundaries
XTOL, RTOL, MITR = 1e-3, 1e-3, 10  # other solver parameters

# user-defined struct for extra parameters
ctypedef struct test_params:
    double C0
    double C1

# user-defined callback
cdef double f(double x, void *args):
    cdef test_params *myargs = <test_params *> args
    return myargs.C0 - math.exp(-(x - myargs.C1))

# Cython wrapper function
cdef double brentq_wrapper_example(dict args, double xa, double xb,
                                   double xtol, double rtol, int mitr):
    # Cython automatically casts dictionary to struct
    cdef test_params myargs = args
    return brentq(
        f, xa, xb, <test_params *> &myargs, xtol, rtol, mitr, NULL)

# Python function
def brentq_example(args=myargs, xa=XLO, xb=XHI, xtol=XTOL, rtol=RTOL,
                   mitr=MITR):
```

(continues on next page)

(continued from previous page)

```
    '''Calls Cython wrapper from Python.'''
    return brentq_wrapper_example(args, xa, xb, xtol, rtol, mitr)
```

4. If you want to call your function from Python, create a Cython wrapper, and a Python function that calls the wrapper, or use `cpdef`. Then, in Python, you can import and run the example.

```
from myexample import brentq_example

x = brentq_example()
# 0.6999942848231314
```

5. Create a Cython `.pxd` file if you need to export any Cython functions.

Full output

The functions in *cython_optimize* can also copy the full output from the solver to a C `struct` that is passed as its last argument. If you don't want the full output, just pass `NULL`. The full output `struct` must be type `zeros_full_output`, which is defined in *scipy.optimize.cython_optimize* with the following fields:

- `int funcalls`: number of function calls
- `int iterations`: number of iterations
- `int error_num`: error number
- `double root`: root of function

The root is copied by *cython_optimize* to the full output `struct`. An error number of -1 means a sign error, -2 means a convergence error, and 0 means the solver converged. Continuing from the previous example:

```
from scipy.optimize.cython_optimize cimport zeros_full_output

# cython brentq solver with full output
cdef brent_full_output brentq_full_output_wrapper_example(
        dict args, double xa, double xb, double xtol, double rtol,
        int mitr):
    cdef test_params myargs = args
    cdef zeros_full_output my_full_output
    # use my_full_output instead of NULL
    brentq(f, xa, xb, &myargs, xtol, rtol, mitr, &my_full_output)
    return my_full_output

# Python function
def brent_full_output_example(args=myargs, xa=XLO, xb=XHI, xtol=XTOL,
                              rtol=RTOL, mitr=MITR):
    '''Returns full output'''
    return brentq_full_output_wrapper_example(args, xa, xb, xtol, rtol,
                                              mitr)

result = brent_full_output_example()
# {'error_num': 0,
#  'funcalls': 6,
```

(continues on next page)

(continued from previous page)

```
#  'iterations': 5,
#  'root': 0.6999942848231314}
```

3.3.22 Signal processing (`scipy.signal`)

Convolution

convolve(in1, in2[, mode, method])	Convolve two N-dimensional arrays.
correlate(in1, in2[, mode, method])	Cross-correlate two N-dimensional arrays.
fftconvolve(in1, in2[, mode, axes])	Convolve two N-dimensional arrays using FFT.
oaconvolve(in1, in2[, mode, axes])	Convolve two N-dimensional arrays using the overlap-add method.
convolve2d(in1, in2[, mode, boundary, fillvalue])	Convolve two 2-dimensional arrays.
correlate2d(in1, in2[, mode, boundary, …])	Cross-correlate two 2-dimensional arrays.
sepfir2d(input, hrow, hcol)	Convolve with a 2-D separable FIR filter.
choose_conv_method(in1, in2[, mode, measure])	Find the fastest convolution/correlation method.
correlation_lags(in1_len, in2_len[, mode])	Calculates the lag / displacement indices array for 1D cross-correlation.

scipy.signal.convolve

scipy.signal.**convolve**(*in1*, *in2*, *mode='full'*, *method='auto'*)

Convolve two N-dimensional arrays.

Convolve *in1* and *in2*, with the output size determined by the *mode* argument.

Parameters

in1 [array_like] First input.

in2 [array_like] Second input. Should have the same number of dimensions as *in1*.

mode [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:

- **full** The output is the full discrete linear convolution of the inputs. (Default)
- **valid** The output consists only of those elements that do not rely on the zero-padding. In 'valid' mode, either *in1* or *in2* must be at least as large as the other in every dimension.
- **same** The output is the same size as *in1*, centered with respect to the 'full' output.

method [str {'auto', 'direct', 'fft'}, optional] A string indicating which method to use to calculate the convolution.

- **direct** The convolution is determined directly from sums, the definition of convolution.
- **fft** The Fourier Transform is used to perform the convolution by calling *fftconvolve*.
- **auto** Automatically chooses direct or Fourier method based on an estimate of which is faster (default). See Notes for more detail.
  New in version 0.19.0.

Returns

convolve [array] An N-dimensional array containing a subset of the discrete linear convolution of *in1* with *in2*.

See also:

numpy.polymul

performs polynomial multiplication (same operation, but also accepts poly1d objects)

choose_conv_method

chooses the fastest appropriate convolution method

fftconvolve

Always uses the FFT method.

oaconvolve

Uses the overlap-add method to do convolution, which is generally faster when the input arrays are large and significantly different in size.

Notes

By default, *convolve* and *correlate* use `method='auto'`, which calls *choose_conv_method* to choose the fastest method using pre-computed values (*choose_conv_method* can also measure real-world timing with a keyword argument). Because *fftconvolve* relies on floating point numbers, there are certain constraints that may force *method=direct* (more detail in *choose_conv_method* docstring).

Examples

Smooth a square pulse using a Hann window:

```
>>> from scipy import signal
>>> sig = np.repeat([0., 1., 0.], 100)
>>> win = signal.windows.hann(50)
>>> filtered = signal.convolve(sig, win, mode='same') / sum(win)
```

```
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_win, ax_filt) = plt.subplots(3, 1, sharex=True)
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('Original pulse')
>>> ax_orig.margins(0, 0.1)
>>> ax_win.plot(win)
>>> ax_win.set_title('Filter impulse response')
>>> ax_win.margins(0, 0.1)
>>> ax_filt.plot(filtered)
>>> ax_filt.set_title('Filtered signal')
>>> ax_filt.margins(0, 0.1)
>>> fig.tight_layout()
>>> fig.show()
```

scipy.signal.correlate

scipy.signal.**correlate**(*in1*, *in2*, *mode='full'*, *method='auto'*)

Cross-correlate two N-dimensional arrays.

Cross-correlate *in1* and *in2*, with the output size determined by the *mode* argument.

Parameters

in1	[array_like] First input.
in2	[array_like] Second input. Should have the same number of dimensions as *in1*.
mode	[str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:

	full	The output is the full discrete linear cross-correlation of the inputs. (Default)
	valid	The output consists only of those elements that do not rely on the zero-padding. In 'valid' mode, either *in1* or *in2* must be at least as large as the other in every dimension.
	same	The output is the same size as *in1*, centered with respect to the 'full' output.
method	[str {'auto', 'direct', 'fft'}, optional] A string indicating which method to use to calculate the correlation.	
	direct	The correlation is determined directly from sums, the definition of correlation.
	fft	The Fast Fourier Transform is used to perform the correlation more quickly (only available for numerical arrays.)
	auto	Automatically chooses direct or Fourier method based on an estimate of which is faster (default). See `convolve` Notes for more detail. New in version 0.19.0.

Returns

correlate	[array] An N-dimensional array containing a subset of the discrete linear cross-correlation of *in1* with *in2*.

See also:

`choose_conv_method`

contains more documentation on *method*.

`correlation_lags`

calculates the lag / displacement indices array for 1D cross-correlation.

Notes

The correlation z of two d-dimensional arrays x and y is defined as:

```
z[...,k,...] = sum[..., i_l, ...] x[..., i_l,...] * conj(y[..., i_l - k,..
↪.])
```

This way, if x and y are 1-D arrays and `z = correlate(x, y, 'full')` then

$$z[k] = (x * y)(k - N + 1) = \sum_{l=0}^{||x||-1} x_l y^*_{l-k+N-1}$$

for $k = 0, 1, ..., ||x|| + ||y|| - 2$

where $||x||$ is the length of `x`, $N = \max(||x||, ||y||)$, and y_m is 0 when m is outside the range of y.

`method='fft'` only works for numerical arrays as it relies on *fftconvolve*. In certain cases (i.e., arrays of objects or when rounding integers can lose precision), `method='direct'` is always used.

When using "same" mode with even-length inputs, the outputs of *correlate* and *correlate2d* differ: There is a 1-index offset between them.

Examples

Implement a matched filter using cross-correlation, to recover a signal that has passed through a noisy channel.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
```

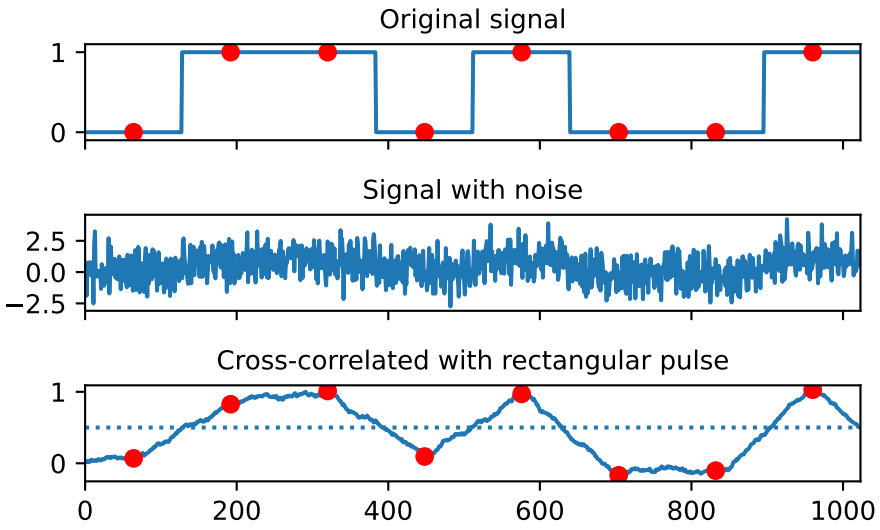
```
>>> sig = np.repeat([0., 1., 1., 0., 1., 0., 0., 1.], 128)
>>> sig_noise = sig + rng.standard_normal(len(sig))
>>> corr = signal.correlate(sig_noise, np.ones(128), mode='same') / 128
```

```
>>> clock = np.arange(64, len(sig), 128)
>>> fig, (ax_orig, ax_noise, ax_corr) = plt.subplots(3, 1, sharex=True)
>>> ax_orig.plot(sig)
>>> ax_orig.plot(clock, sig[clock], 'ro')
>>> ax_orig.set_title('Original signal')
>>> ax_noise.plot(sig_noise)
>>> ax_noise.set_title('Signal with noise')
>>> ax_corr.plot(corr)
>>> ax_corr.plot(clock, corr[clock], 'ro')
>>> ax_corr.axhline(0.5, ls=':')
>>> ax_corr.set_title('Cross-correlated with rectangular pulse')
>>> ax_orig.margins(0, 0.1)
>>> fig.tight_layout()
>>> plt.show()
```

Compute the cross-correlation of a noisy signal with the original signal.

```
>>> x = np.arange(128) / 128
>>> sig = np.sin(2 * np.pi * x)
>>> sig_noise = sig + rng.standard_normal(len(sig))
```

(continues on next page)



(continued from previous page)

```
>>> corr = signal.correlate(sig_noise, sig)
>>> lags = signal.correlation_lags(len(sig), len(sig_noise))
>>> corr /= np.max(corr)
```

```
>>> fig, (ax_orig, ax_noise, ax_corr) = plt.subplots(3, 1, figsize=(4.8,␣
↪4.8))
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('Original signal')
>>> ax_orig.set_xlabel('Sample Number')
>>> ax_noise.plot(sig_noise)
>>> ax_noise.set_title('Signal with noise')
>>> ax_noise.set_xlabel('Sample Number')
>>> ax_corr.plot(lags, corr)
>>> ax_corr.set_title('Cross-correlated signal')
>>> ax_corr.set_xlabel('Lag')
>>> ax_orig.margins(0, 0.1)
>>> ax_noise.margins(0, 0.1)
>>> ax_corr.margins(0, 0.1)
>>> fig.tight_layout()
>>> plt.show()
```

scipy.signal.fftconvolve

scipy.signal.**fftconvolve**(*in1*, *in2*, *mode='full'*, *axes=None*)

Convolve two N-dimensional arrays using FFT.

Convolve *in1* and *in2* using the fast Fourier transform method, with the output size determined by the *mode* argument.

This is generally much faster than *convolve* for large arrays (n > ~500), but can be slower when only a few output values are needed, and can only output float arrays (int or object array inputs will be cast to float).

As of v0.19, *convolve* automatically chooses this method or the direct method based on an estimation of which is faster.

Lag

Parameters

in1 [array_like] First input.

in2 [array_like] Second input. Should have the same number of dimensions as *in1*.

mode [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:

- **full** The output is the full discrete linear convolution of the inputs. (Default)
- **valid** The output consists only of those elements that do not rely on the zero-padding. In 'valid' mode, either *in1* or *in2* must be at least as large as the other in every dimension.
- **same** The output is the same size as *in1*, centered with respect to the 'full' output.

axes [int or array_like of ints or None, optional] Axes over which to compute the convolution. The default is over all axes.

Returns

out [array] An N-dimensional array containing a subset of the discrete linear convolution of *in1* with *in2*.

See also:

convolve

Uses the direct convolution or FFT convolution algorithm depending on which is faster.

oaconvolve

Uses the overlap-add method to do convolution, which is generally faster when the input arrays are large and significantly different in size.

Examples

Autocorrelation of white noise is an impulse.

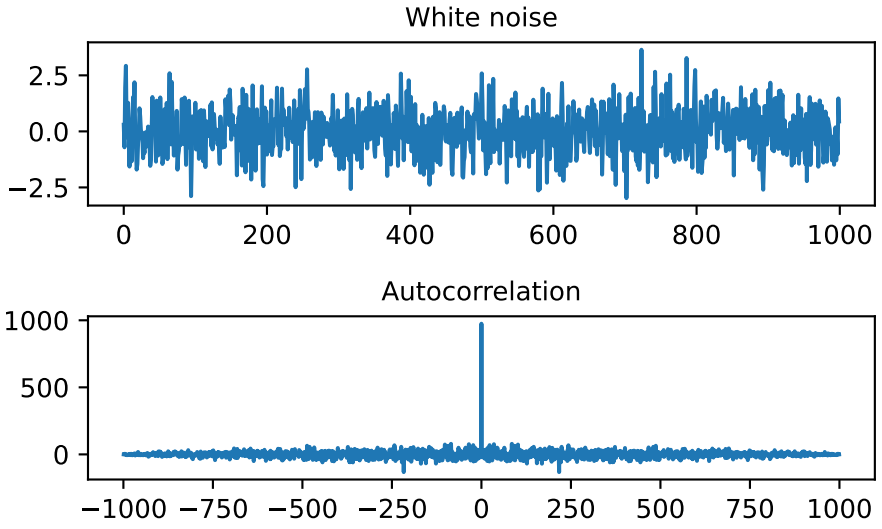
```
>>> from scipy import signal
>>> rng = np.random.default_rng()
>>> sig = rng.standard_normal(1000)
>>> autocorr = signal.fftconvolve(sig, sig[::-1], mode='full')
```

```
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_mag) = plt.subplots(2, 1)
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('White noise')
>>> ax_mag.plot(np.arange(-len(sig)+1,len(sig)), autocorr)
>>> ax_mag.set_title('Autocorrelation')
>>> fig.tight_layout()
>>> fig.show()
```

Gaussian blur implemented using FFT convolution. Notice the dark borders around the image, due to the zero-padding beyond its boundaries. The *convolve2d* function allows for other types of image boundaries, but is far slower.

```
>>> from scipy import misc
>>> face = misc.face(gray=True)
>>> kernel = np.outer(signal.windows.gaussian(70, 8),
...                   signal.windows.gaussian(70, 8))
>>> blurred = signal.fftconvolve(face, kernel, mode='same')
```

```
>>> fig, (ax_orig, ax_kernel, ax_blurred) = plt.subplots(3, 1,
...                                                      figsize=(6, 15))
>>> ax_orig.imshow(face, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_kernel.imshow(kernel, cmap='gray')
>>> ax_kernel.set_title('Gaussian kernel')
>>> ax_kernel.set_axis_off()
>>> ax_blurred.imshow(blurred, cmap='gray')
>>> ax_blurred.set_title('Blurred')
>>> ax_blurred.set_axis_off()
>>> fig.show()
```



scipy.signal.oaconvolve

`scipy.signal.`**`oaconvolve`**(*in1*, *in2*, *mode='full'*, *axes=None*)

Convolve two N-dimensional arrays using the overlap-add method.

Convolve *in1* and *in2* using the overlap-add method, with the output size determined by the *mode* argument.

This is generally much faster than *convolve* for large arrays (n > ~500), and generally much faster than *fftconvolve* when one array is much larger than the other, but can be slower when only a few output values are needed or when the arrays are very similar in shape, and can only output float arrays (int or object array inputs will be cast to float).

Parameters

in1 [array_like] First input.

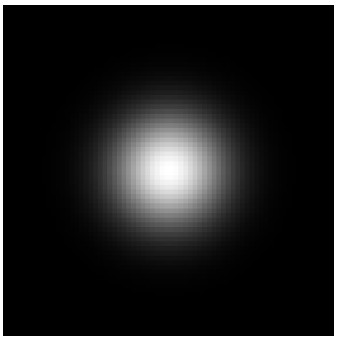
in2 [array_like] Second input. Should have the same number of dimensions as *in1*.

mode [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:

- **full** The output is the full discrete linear convolution of the inputs. (Default)
- **valid** The output consists only of those elements that do not rely on the zero-padding. In 'valid' mode, either *in1* or *in2* must be at least as large as the other in every dimension.
- **same** The output is the same size as *in1*, centered with respect to the 'full' output.

Original

Gaussian kernel



Blurred

axes [int or array_like of ints or None, optional] Axes over which to compute the convolution. The default is over all axes.

Returns

out [array] An N-dimensional array containing a subset of the discrete linear convolution of *in1* with *in2*.

See also:

convolve

Uses the direct convolution or FFT convolution algorithm depending on which is faster.

fftconvolve

An implementation of convolution using FFT.

Notes

New in version 1.4.0.

References

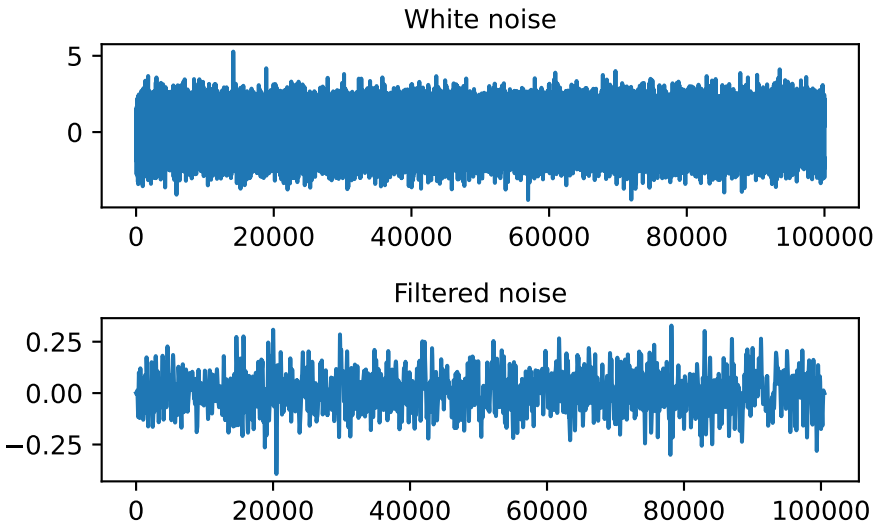
[1], [2]

Examples

Convolve a 100,000 sample signal with a 512-sample filter.

```
>>> from scipy import signal
>>> rng = np.random.default_rng()
>>> sig = rng.standard_normal(100000)
>>> filt = signal.firwin(512, 0.01)
>>> fsig = signal.oaconvolve(sig, filt)
```

```
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_mag) = plt.subplots(2, 1)
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('White noise')
>>> ax_mag.plot(fsig)
>>> ax_mag.set_title('Filtered noise')
>>> fig.tight_layout()
>>> fig.show()
```



scipy.signal.convolve2d

`scipy.signal.`**`convolve2d`**(*in1*, *in2*, *mode='full'*, *boundary='fill'*, *fillvalue=0*)

Convolve two 2-dimensional arrays.

Convolve *in1* and *in2* with output size determined by *mode*, and boundary conditions determined by *boundary* and *fillvalue*.

Parameters

in1 [array_like] First input.

in2 [array_like] Second input. Should have the same number of dimensions as *in1*.

mode [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:

- **`full`** The output is the full discrete linear convolution of the inputs. (Default)
- **`valid`** The output consists only of those elements that do not rely on the zero-padding. In 'valid' mode, either *in1* or *in2* must be at least as large as the other in every dimension.
- **`same`** The output is the same size as *in1*, centered with respect to the 'full' output.

boundary [str {'fill', 'wrap', 'symm'}, optional] A flag indicating how to handle boundaries:

- **`fill`** pad input arrays with fillvalue. (default)
- **`wrap`** circular boundary conditions.
- **`symm`** symmetrical boundary conditions.

fillvalue [scalar, optional] Value to fill pad input arrays with. Default is 0.

Returns

out [ndarray] A 2-dimensional array containing a subset of the discrete linear convolution of *in1* with *in2*.

Examples

Compute the gradient of an image by 2D convolution with a complex Scharr operator. (Horizontal operator is real, vertical is imaginary.) Use symmetric boundary condition to avoid creating edges at the image boundaries.

```
>>> from scipy import signal
>>> from scipy import misc
>>> ascent = misc.ascent()
>>> scharr = np.array([[ -3-3j, 0-10j,  +3 -3j],
...                    [-10+0j, 0+ 0j, +10 +0j],
...                    [ -3+3j, 0+10j,  +3 +3j]]) # Gx + j*Gy
>>> grad = signal.convolve2d(ascent, scharr, boundary='symm', mode='same')
```

```
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_mag, ax_ang) = plt.subplots(3, 1, figsize=(6, 15))
>>> ax_orig.imshow(ascent, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_mag.imshow(np.absolute(grad), cmap='gray')
>>> ax_mag.set_title('Gradient magnitude')
>>> ax_mag.set_axis_off()
>>> ax_ang.imshow(np.angle(grad), cmap='hsv') # hsv is cyclic, like angles
>>> ax_ang.set_title('Gradient orientation')
>>> ax_ang.set_axis_off()
>>> fig.show()
```

scipy.signal.correlate2d

scipy.signal.**correlate2d**(*in1*, *in2*, *mode='full'*, *boundary='fill'*, *fillvalue=0*)

Cross-correlate two 2-dimensional arrays.

Cross correlate *in1* and *in2* with output size determined by *mode*, and boundary conditions determined by *boundary* and *fillvalue*.

Parameters

in1 [array_like] First input.

in2 [array_like] Second input. Should have the same number of dimensions as *in1*.

mode [str {'full', 'valid', 'same'}, optional] A string indicating the size of the output:

- **full** The output is the full discrete linear cross-correlation of the inputs. (Default)
- **valid** The output consists only of those elements that do not rely on the zero-padding. In 'valid' mode, either *in1* or *in2* must be at least as large as the other in every dimension.
- **same** The output is the same size as *in1*, centered with respect to the 'full' output.

boundary [str {'fill', 'wrap', 'symm'}, optional] A flag indicating how to handle boundaries:

- **fill** pad input arrays with fillvalue. (default)
- **wrap** circular boundary conditions.
- **symm** symmetrical boundary conditions.

fillvalue [scalar, optional] Value to fill pad input arrays with. Default is 0.

Returns

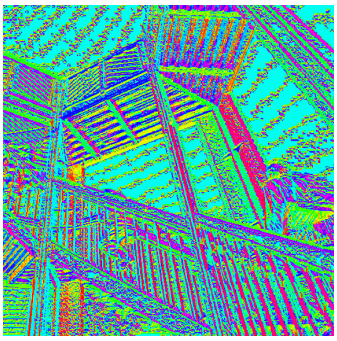
correlate2d

[ndarray] A 2-dimensional array containing a subset of the discrete linear cross-correlation of *in1* with *in2*.

Original

Gradient magnitude

Gradient orientation



Notes

When using "same" mode with even-length inputs, the outputs of *correlate* and *correlate2d* differ: There is a 1-index offset between them.

Examples

Use 2D cross-correlation to find the location of a template in a noisy image:

```
>>> from scipy import signal
>>> from scipy import misc
>>> rng = np.random.default_rng()
>>> face = misc.face(gray=True) - misc.face(gray=True).mean()
>>> template = np.copy(face[300:365, 670:750])  # right eye
>>> template -= template.mean()
>>> face = face + rng.standard_normal(face.shape) * 50  # add noise
>>> corr = signal.correlate2d(face, template, boundary='symm', mode='same
 ↪')
>>> y, x = np.unravel_index(np.argmax(corr), corr.shape)  # find the match
```

```
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_template, ax_corr) = plt.subplots(3, 1,
...                                                     figsize=(6, 15))
>>> ax_orig.imshow(face, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_template.imshow(template, cmap='gray')
>>> ax_template.set_title('Template')
>>> ax_template.set_axis_off()
>>> ax_corr.imshow(corr, cmap='gray')
>>> ax_corr.set_title('Cross-correlation')
>>> ax_corr.set_axis_off()
>>> ax_orig.plot(x, y, 'ro')
>>> fig.show()
```

scipy.signal.sepfir2d

scipy.signal.**sepfir2d**(*input*, *hrow*, *hcol*)

Convolve with a 2-D separable FIR filter.

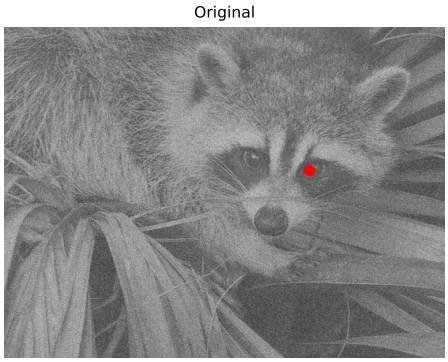
Convolve the rank-2 input array with the separable filter defined by the rank-1 arrays hrow, and hcol. Mirror symmetric boundary conditions are assumed. This function can be used to find an image given its B-spline representation.

Parameters

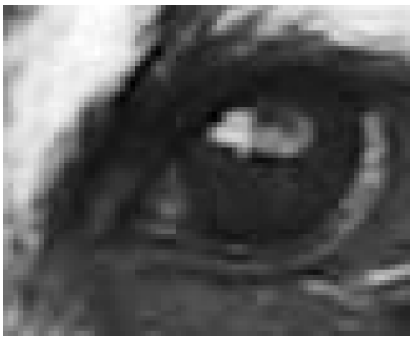
input	[ndarray] The input signal. Must be a rank-2 array.
hrow	[ndarray] A rank-1 array defining the row direction of the filter. Must be odd-length
hcol	[ndarray] A rank-1 array defining the column direction of the filter. Must be odd-length

Returns

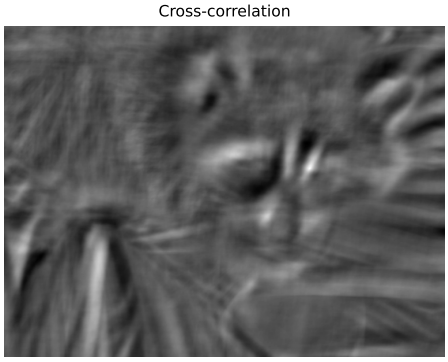
output	[ndarray] The filtered signal.



Original



Template



Cross-correlation

Examples

Examples are given *in the tutorial*.

scipy.signal.choose_conv_method

scipy.signal.**choose_conv_method**(*in1*, *in2*, *mode='full'*, *measure=False*)

Find the fastest convolution/correlation method.

This primarily exists to be called during the `method='auto'` option in *convolve* and *correlate*. It can also be used to determine the value of `method` for many different convolutions of the same dtype/shape. In addition, it supports timing the convolution to adapt the value of `method` to a particular set of inputs and/or hardware.

Parameters

in1	[array_like] The first argument passed into the convolution function.
in2	[array_like] The second argument passed into the convolution function.
mode	[str {'full', 'valid', 'same'}, optional] A string indicating the size of the output: **full** The output is the full discrete linear convolution of the inputs. (Default) **valid** The output consists only of those elements that do not rely on the zero-padding. **same** The output is the same size as *in1*, centered with respect to the 'full' output.
measure	[bool, optional] If True, run and time the convolution of *in1* and *in2* with both methods and return the fastest. If False (default), predict the fastest method using precomputed values.

Returns

method	[str] A string indicating which convolution method is fastest, either 'direct' or 'fft'
times	[dict, optional] A dictionary containing the times (in seconds) needed for each method. This value is only returned if `measure=True`.

See also:

convolve

correlate

Notes

Generally, this method is 99% accurate for 2D signals and 85% accurate for 1D signals for randomly chosen input sizes. For precision, use `measure=True` to find the fastest method by timing the convolution. This can be used to avoid the minimal overhead of finding the fastest `method` later, or to adapt the value of `method` to a particular set of inputs.

Experiments were run on an Amazon EC2 r5a.2xlarge machine to test this function. These experiments measured the ratio between the time required when using `method='auto'` and the time required for the fastest method (i.e., `ratio = time_auto / min(time_fft, time_direct)`). In these experiments, we found:

- There is a 95% chance of this ratio being less than 1.5 for 1D signals and a 99% chance of being less than 2.5 for 2D signals.
- The ratio was always less than 2.5/5 for 1D/2D signals respectively.
- This function is most inaccurate for 1D convolutions that take between 1 and 10 milliseconds with `method='direct'`. A good proxy for this (at least in our experiments) is `1e6 <= in1.size * in2.size <= 1e7`.

The 2D results almost certainly generalize to 3D/4D/etc because the implementation is the same (the 1D implementation is different).

All the numbers above are specific to the EC2 machine. However, we did find that this function generalizes fairly decently across hardware. The speed tests were of similar quality (and even slightly better) than the same tests performed on the machine to tune this function's numbers (a mid-2014 15-inch MacBook Pro with 16GB RAM and a 2.5GHz Intel i7 processor).

There are cases when *fftconvolve* supports the inputs but this function returns *direct* (e.g., to protect against floating point integer precision).

New in version 0.19.

Examples

Estimate the fastest method for a given input:

```
>>> from scipy import signal
>>> rng = np.random.default_rng()
>>> img = rng.random((32, 32))
>>> filter = rng.random((8, 8))
>>> method = signal.choose_conv_method(img, filter, mode='same')
>>> method
'fft'
```

This can then be applied to other arrays of the same dtype and shape:

```
>>> img2 = rng.random((32, 32))
>>> filter2 = rng.random((8, 8))
>>> corr2 = signal.correlate(img2, filter2, mode='same', method=method)
>>> conv2 = signal.convolve(img2, filter2, mode='same', method=method)
```

The output of this function (`method`) works with *correlate* and *convolve*.

scipy.signal.correlation_lags

scipy.signal.**correlation_lags**(*in1_len*, *in2_len*, *mode='full'*)

Calculates the lag / displacement indices array for 1D cross-correlation.

Parameters

in1_size	[int] First input size.
in2_size	[int] Second input size.
mode	[str {'full', 'valid', 'same'}, optional] A string indicating the size of the output. See the documentation *correlate* for more information.

Returns

lags	[array] Returns an array containing cross-correlation lag/displacement indices. Indices can be indexed with the np.argmax of the correlation to return the lag/displacement.

See also:

correlate

Compute the N-dimensional cross-correlation.

Notes

Cross-correlation for continuous functions f and g is defined as:

$$(f \star g)(\tau) \triangleq \int_{t_0}^{t_0+T} \overline{f(t)} g(t+\tau)\, dt$$

Where τ is defined as the displacement, also known as the lag.

Cross correlation for discrete functions f and g is defined as:

$$(f \star g)[n] \triangleq \sum_{-\infty}^{\infty} \overline{f[m]} g[m+n]$$

Where n is the lag.

Examples

Cross-correlation of a signal with its time-delayed self.

```
>>> from scipy import signal
>>> from numpy.random import default_rng
>>> rng = default_rng()
>>> x = rng.standard_normal(1000)
>>> y = np.concatenate([rng.standard_normal(100), x])
>>> correlation = signal.correlate(x, y, mode="full")
>>> lags = signal.correlation_lags(x.size, y.size, mode="full")
>>> lag = lags[np.argmax(correlation)]
```

B-splines

bspline(x, n)	B-spline basis function of order n.
cubic(x)	A cubic B-spline.
quadratic(x)	A quadratic B-spline.
gauss_spline(x, n)	Gaussian approximation to B-spline basis function of order n.
cspline1d(signal[, lamb])	Compute cubic spline coefficients for rank-1 array.
qspline1d(signal[, lamb])	Compute quadratic spline coefficients for rank-1 array.
cspline2d(input[, lambda, precision])	Coefficients for 2-D cubic (3rd order) B-spline.
qspline2d(input[, lambda, precision])	Coefficients for 2-D quadratic (2nd order) B-spline:
cspline1d_eval(cj, newx[, dx, x0])	Evaluate a cubic spline at the new set of points.
qspline1d_eval(cj, newx[, dx, x0])	Evaluate a quadratic spline at the new set of points.
spline_filter(Iin[, lmbda])	Smoothing spline (cubic) filtering of a rank-2 array.

scipy.signal.bspline

scipy.signal.**bspline**(*x*, *n*)

B-spline basis function of order n.

Parameters

x	[array_like] a knot vector
n	[int] The order of the spline. Must be non-negative, i.e., n >= 0

Returns

res	[ndarray] B-spline basis function values

See also:

cubic

A cubic B-spline.

quadratic

A quadratic B-spline.

Notes

Uses numpy.piecewise and automatic function-generator.

Examples

We can calculate B-Spline basis function of several orders:

```
>>> from scipy.signal import bspline, cubic, quadratic
>>> bspline(0.0, 1)
1
```

```
>>> knots = [-1.0, 0.0, -1.0]
>>> bspline(knots, 2)
array([0.125, 0.75, 0.125])
```

```
>>> np.array_equal(bspline(knots, 2), quadratic(knots))
True
```

```
>>> np.array_equal(bspline(knots, 3), cubic(knots))
True
```

scipy.signal.cubic

scipy.signal.**cubic**(*x*)

A cubic B-spline.

This is a special case of *bspline*, and equivalent to `bspline(x, 3)`.

Parameters

x	[array_like] a knot vector

Returns

res [ndarray] Cubic B-spline basis function values

See also:

bspline

B-spline basis function of order n

quadratic

A quadratic B-spline.

Examples

We can calculate B-Spline basis function of several orders:

```
>>> from scipy.signal import bspline, cubic, quadratic
>>> bspline(0.0, 1)
1
```

```
>>> knots = [-1.0, 0.0, -1.0]
>>> bspline(knots, 2)
array([0.125, 0.75, 0.125])
```

```
>>> np.array_equal(bspline(knots, 2), quadratic(knots))
True
```

```
>>> np.array_equal(bspline(knots, 3), cubic(knots))
True
```

scipy.signal.quadratic

scipy.signal.**quadratic**(*x*)

A quadratic B-spline.

This is a special case of *bspline*, and equivalent to `bspline(x, 2)`.

Parameters

x [array_like] a knot vector

Returns

res [ndarray] Quadratic B-spline basis function values

See also:

bspline

B-spline basis function of order n

cubic

A cubic B-spline.

Examples

We can calculate B-Spline basis function of several orders:

```
>>> from scipy.signal import bspline, cubic, quadratic
>>> bspline(0.0, 1)
1
```

```
>>> knots = [-1.0, 0.0, -1.0]
>>> bspline(knots, 2)
array([0.125, 0.75, 0.125])
```

```
>>> np.array_equal(bspline(knots, 2), quadratic(knots))
True
```

```
>>> np.array_equal(bspline(knots, 3), cubic(knots))
True
```

scipy.signal.gauss_spline

scipy.signal.**gauss_spline**(*x*, *n*)

Gaussian approximation to B-spline basis function of order n.

Parameters

x	[array_like] a knot vector
n	[int] The order of the spline. Must be non-negative, i.e., n >= 0

Returns

res	[ndarray] B-spline basis function values approximated by a zero-mean Gaussian function.

Notes

The B-spline basis function can be approximated well by a zero-mean Gaussian function with standard-deviation equal to $\sigma = (n+1)/12$ for large n :

$$\frac{1}{\sqrt{2\pi\sigma^2}} exp(-\frac{x^2}{2\sigma})$$

References

[1], [2]

Examples

We can calculate B-Spline basis functions approximated by a gaussian distribution:

```
>>> from scipy.signal import gauss_spline, bspline
>>> knots = np.array([-1.0, 0.0, -1.0])
>>> gauss_spline(knots, 3)
array([0.15418033, 0.6909883, 0.15418033])  # may vary
```

```
>>> bspline(knots, 3)
array([0.16666667, 0.66666667, 0.16666667])  # may vary
```

scipy.signal.cspline1d

scipy.signal.**cspline1d**(*signal*, *lamb=0.0*)

Compute cubic spline coefficients for rank-1 array.

Find the cubic spline coefficients for a 1-D signal assuming mirror-symmetric boundary conditions. To obtain the signal back from the spline representation mirror-symmetric-convolve these coefficients with a length 3 FIR window [1.0, 4.0, 1.0]/ 6.0 .

Parameters

signal	[ndarray] A rank-1 array representing samples of a signal.
lamb	[float, optional] Smoothing coefficient, default is 0.0.

Returns

c	[ndarray] Cubic spline coefficients.

See also:

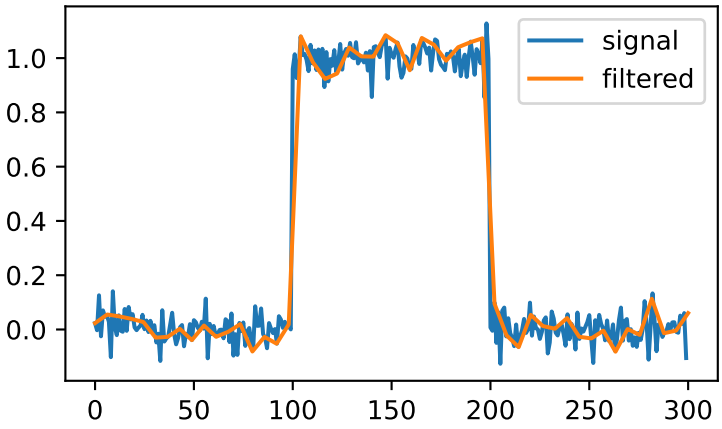
cspline1d_eval

Evaluate a cubic spline at the new set of points.

Examples

We can filter a signal to reduce and smooth out high-frequency noise with a cubic spline:

```
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import cspline1d, cspline1d_eval
>>> rng = np.random.default_rng()
>>> sig = np.repeat([0., 1., 0.], 100)
>>> sig += rng.standard_normal(len(sig))*0.05  # add noise
>>> time = np.linspace(0, len(sig))
>>> filtered = cspline1d_eval(cspline1d(sig), time)
>>> plt.plot(sig, label="signal")
>>> plt.plot(time, filtered, label="filtered")
>>> plt.legend()
>>> plt.show()
```



scipy.signal.qspline1d

`scipy.signal.`**`qspline1d`**(*signal*, *lamb=0.0*)

Compute quadratic spline coefficients for rank-1 array.

Parameters

signal	[ndarray] A rank-1 array representing samples of a signal.
lamb	[float, optional] Smoothing coefficient (must be zero for now).

Returns

c	[ndarray] Quadratic spline coefficients.

See also:

`qspline1d_eval`

Evaluate a quadratic spline at the new set of points.

Notes

Find the quadratic spline coefficients for a 1-D signal assuming mirror-symmetric boundary conditions. To obtain the signal back from the spline representation mirror-symmetric-convolve these coefficients with a length 3 FIR window [1.0, 6.0, 1.0]/ 8.0 .

Examples

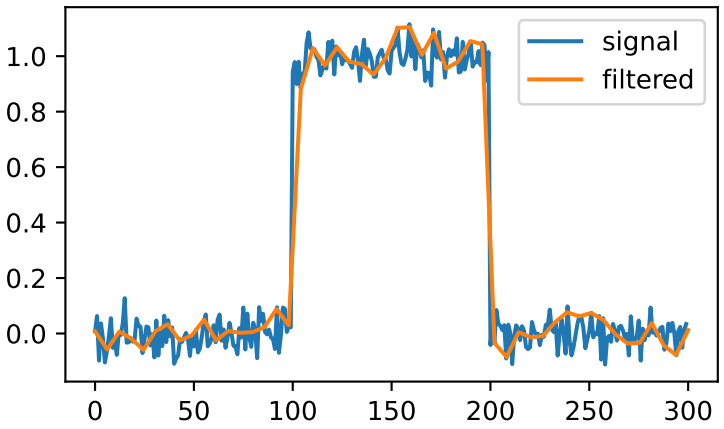
We can filter a signal to reduce and smooth out high-frequency noise with a quadratic spline:

```
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import qspline1d, qspline1d_eval
>>> rng = np.random.default_rng()
>>> sig = np.repeat([0., 1., 0.], 100)
>>> sig += rng.standard_normal(len(sig))*0.05  # add noise
>>> time = np.linspace(0, len(sig))
```

(continues on next page)

(continued from previous page)

```
>>> filtered = qspline1d_eval(qspline1d(sig), time)
>>> plt.plot(sig, label="signal")
>>> plt.plot(time, filtered, label="filtered")
>>> plt.legend()
>>> plt.show()
```



scipy.signal.cspline2d

`scipy.signal.`**`cspline2d`**(*input*, *lambda=0.0*, *precision=-1.0*)

Coefficients for 2-D cubic (3rd order) B-spline.

Return the third-order B-spline coefficients over a regularly spaced input grid for the two-dimensional input image.

Parameters

input	[ndarray] The input signal.
lambda	[float] Specifies the amount of smoothing in the transfer function.
precision	[float] Specifies the precision for computing the infinite sum needed to apply mirror- symmetric boundary conditions.

Returns

output	[ndarray] The filtered signal.

Examples

Examples are given *in the tutorial*.

scipy.signal.qspline2d

scipy.signal.**qspline2d**(*input*, *lambda=0.0*, *precision=-1.0*)

Coefficients for 2-D quadratic (2nd order) B-spline:

Return the second-order B-spline coefficients over a regularly spaced input grid for the two-dimensional input image.

Parameters

input	[ndarray] The input signal.
lambda	[float] Specifies the amount of smoothing in the transfer function.
precision	[float] Specifies the precision for computing the infinite sum needed to apply mirror- symmetric boundary conditions.

Returns

output	[ndarray] The filtered signal.

Examples

Examples are given *in the tutorial*.

scipy.signal.cspline1d_eval

scipy.signal.**cspline1d_eval**(*cj*, *newx*, *dx=1.0*, *x0=0*)

Evaluate a cubic spline at the new set of points.

dx is the old sample-spacing while *x0* was the old origin. In other-words the old-sample points (knot-points) for which the *cj* represent spline coefficients were at equally-spaced points of:

oldx = x0 + j*dx j=0…N-1, with N=len(cj)

Edges are handled using mirror-symmetric boundary conditions.

Parameters

cj	[ndarray] cublic spline coefficients
newx	[ndarray] New set of points.
dx	[float, optional] Old sample-spacing, the default value is 1.0.
x0	[int, optional] Old origin, the default value is 0.

Returns

res	[ndarray] Evaluated a cubic spline points.

See also:

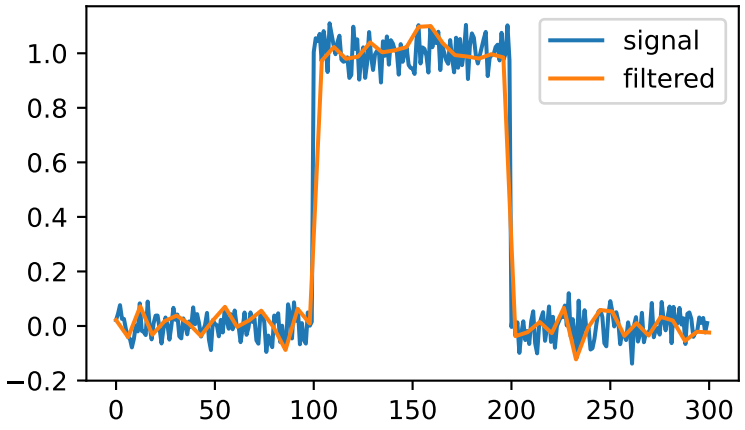
cspline1d

Compute cubic spline coefficients for rank-1 array.

Examples

We can filter a signal to reduce and smooth out high-frequency noise with a cubic spline:

```
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import cspline1d, cspline1d_eval
>>> rng = np.random.default_rng()
>>> sig = np.repeat([0., 1., 0.], 100)
>>> sig += rng.standard_normal(len(sig))*0.05  # add noise
>>> time = np.linspace(0, len(sig))
>>> filtered = cspline1d_eval(cspline1d(sig), time)
>>> plt.plot(sig, label="signal")
>>> plt.plot(time, filtered, label="filtered")
>>> plt.legend()
>>> plt.show()
```



scipy.signal.qspline1d_eval

scipy.signal.**qspline1d_eval**(*cj*, *newx*, *dx=1.0*, *x0=0*)

Evaluate a quadratic spline at the new set of points.

Parameters

cj	[ndarray] Quadratic spline coefficients
newx	[ndarray] New set of points.
dx	[float, optional] Old sample-spacing, the default value is 1.0.
x0	[int, optional] Old origin, the default value is 0.

Returns

res	[ndarray] Evaluated a quadratic spline points.

See also:

qspline1d

Compute quadratic spline coefficients for rank-1 array.

Notes

dx is the old sample-spacing while *x0* was the old origin. In other-words the old-sample points (knot-points) for which the *cj* represent spline coefficients were at equally-spaced points of:

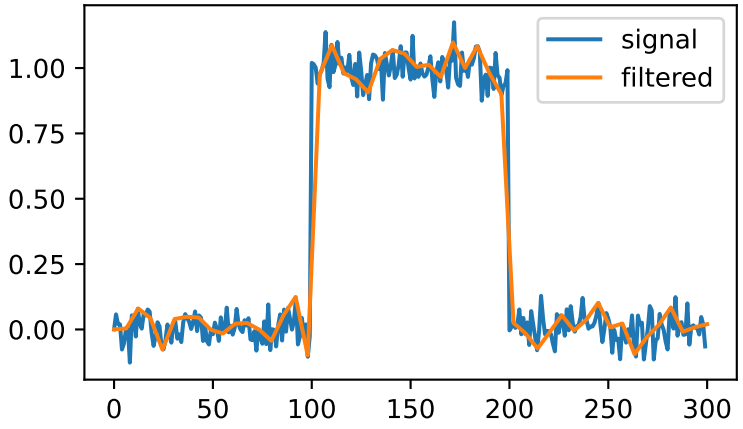
```
oldx = x0 + j*dx  j=0...N-1, with N=len(cj)
```

Edges are handled using mirror-symmetric boundary conditions.

Examples

We can filter a signal to reduce and smooth out high-frequency noise with a quadratic spline:

```
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import qspline1d, qspline1d_eval
>>> rng = np.random.default_rng()
>>> sig = np.repeat([0., 1., 0.], 100)
>>> sig += rng.standard_normal(len(sig))*0.05  # add noise
>>> time = np.linspace(0, len(sig))
>>> filtered = qspline1d_eval(qspline1d(sig), time)
>>> plt.plot(sig, label="signal")
>>> plt.plot(time, filtered, label="filtered")
>>> plt.legend()
>>> plt.show()
```



scipy.signal.spline_filter

scipy.signal.**spline_filter**(*Iin*, *lmbda=5.0*)

Smoothing spline (cubic) filtering of a rank-2 array.

Filter an input data set, *Iin*, using a (cubic) smoothing spline of fall-off *lmbda*.

Parameters

Iin	[array_like] input data set
lmbda	[float, optional] spline smooghing fall-off value, default is *5.0*.

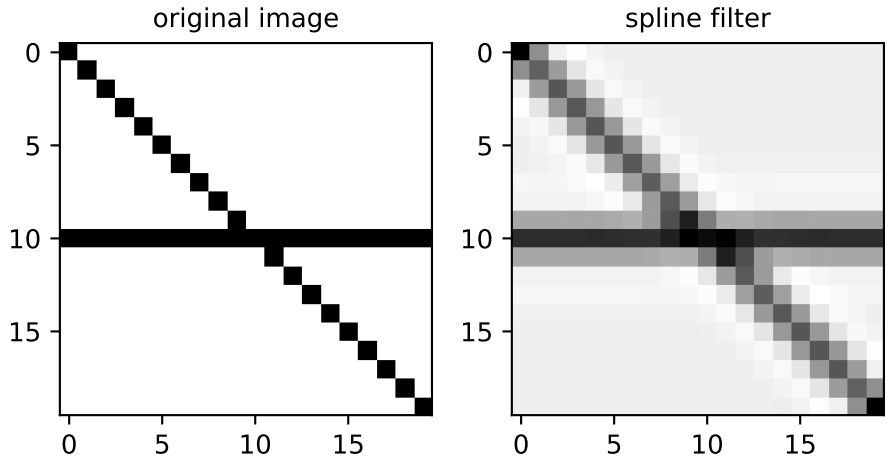
Returns

res	[ndarray] filterd input data

Examples

We can filter an multi dimentional signal (ex: 2D image) using cubic B-spline filter:

```
>>> from scipy.signal import spline_filter
>>> import matplotlib.pyplot as plt
>>> orig_img = np.eye(20)  # create an image
>>> orig_img[10, :] = 1.0
>>> sp_filter = spline_filter(orig_img, lmbda=0.1)
>>> f, ax = plt.subplots(1, 2, sharex=True)
>>> for ind, data in enumerate([[orig_img, "original image"],
...                             [sp_filter, "spline filter"]]):
...     ax[ind].imshow(data[0], cmap='gray_r')
...     ax[ind].set_title(data[1])
>>> plt.tight_layout()
>>> plt.show()
```



Filtering

order_filter(a, domain, rank)	Perform an order filter on an N-D array.
medfilt(volume[, kernel_size])	Perform a median filter on an N-dimensional array.
medfilt2d(input[, kernel_size])	Median filter a 2-dimensional array.
wiener(im[, mysize, noise])	Perform a Wiener filter on an N-dimensional array.
symiirorder1(input, c0, z1[, precision])	Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of first-order sections. The second section uses a reversed sequence. This implements a system with the following transfer function and mirror-symmetric boundary conditions::.
symiirorder2(input, r, omega[, precision])	Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of second-order sections. The second section uses a reversed sequence. This implements the following transfer function::.
lfilter(b, a, x[, axis, zi])	Filter data along one-dimension with an IIR or FIR filter.
lfiltic(b, a, y[, x])	Construct initial conditions for lfilter given input and output vectors.
lfilter_zi(b, a)	Construct initial conditions for lfilter for step response steady-state.
filtfilt(b, a, x[, axis, padtype, padlen, …])	Apply a digital filter forward and backward to a signal.
savgol_filter(x, window_length, polyorder[, …])	Apply a Savitzky-Golay filter to an array.
deconvolve(signal, divisor)	Deconvolves `divisor` out of `signal` using inverse filtering.
sosfilt(sos, x[, axis, zi])	Filter data along one dimension using cascaded second-order sections.
sosfilt_zi(sos)	Construct initial conditions for sosfilt for step response steady-state.
sosfiltfilt(sos, x[, axis, padtype, padlen])	A forward-backward digital filter using cascaded second-order sections.
hilbert(x[, N, axis])	Compute the analytic signal, using the Hilbert transform.
hilbert2(x[, N])	Compute the '2-D' analytic signal of *x*
decimate(x, q[, n, ftype, axis, zero_phase])	Downsample the signal after applying an anti-aliasing filter.
detrend(data[, axis, type, bp, overwrite_data])	Remove linear trend along axis from data.
resample(x, num[, t, axis, window, domain])	Resample *x* to *num* samples using Fourier method along the given axis.
resample_poly(x, up, down[, axis, window, …])	Resample *x* along the given axis using polyphase filtering.
upfirdn(h, x[, up, down, axis, mode, cval])	Upsample, FIR filter, and downsample.

scipy.signal.order_filter

scipy.signal.**order_filter**(*a*, *domain*, *rank*)

Perform an order filter on an N-D array.

Perform an order filter on the array in. The domain argument acts as a mask centered over each pixel. The non-zero elements of domain are used to select elements surrounding each input pixel which are placed in a list. The list is sorted, and the output for that pixel is the element corresponding to rank in the sorted list.

Parameters

a [ndarray] The N-dimensional input array.

domain [array_like] A mask array with the same number of dimensions as *a*. Each dimension should have an odd number of elements.

rank [int] A non-negative integer which selects the element from the sorted list (0 corresponds to the smallest element, 1 is the next smallest element, etc.).

Returns

out [ndarray] The results of the order filter in an array with the same shape as *a*.

Examples

```
>>> from scipy import signal
>>> x = np.arange(25).reshape(5, 5)
>>> domain = np.identity(3)
>>> x
array([[ 0,  1,  2,  3,  4],
       [ 5,  6,  7,  8,  9],
       [10, 11, 12, 13, 14],
       [15, 16, 17, 18, 19],
       [20, 21, 22, 23, 24]])
>>> signal.order_filter(x, domain, 0)
array([[  0.,   0.,   0.,   0.,   0.],
       [  0.,   0.,   1.,   2.,   0.],
       [  0.,   5.,   6.,   7.,   0.],
       [  0.,  10.,  11.,  12.,   0.],
       [  0.,   0.,   0.,   0.,   0.]])
>>> signal.order_filter(x, domain, 2)
array([[  6.,   7.,   8.,   9.,   4.],
       [ 11.,  12.,  13.,  14.,   9.],
       [ 16.,  17.,  18.,  19.,  14.],
       [ 21.,  22.,  23.,  24.,  19.],
       [ 20.,  21.,  22.,  23.,  24.]])
```

scipy.signal.medfilt

`scipy.signal.`**`medfilt`**(*volume*, *kernel_size=None*)

Perform a median filter on an N-dimensional array.

Apply a median filter to the input array using a local window-size given by *kernel_size*. The array will automatically be zero-padded.

Parameters

volume [array_like] An N-dimensional input array.

kernel_size [array_like, optional] A scalar or an N-length list giving the size of the median filter window in each dimension. Elements of *kernel_size* should be odd. If *kernel_size* is a scalar, then this scalar is used as the size in each dimension. Default size is 3 for each dimension.

Returns

out [ndarray] An array the same size as input containing the median filtered result.

Warns

UserWarning If array size is smaller than kernel size along any dimension

See also:

scipy.ndimage.median_filter

scipy.signal.medfilt2d

Notes

The more general function *scipy.ndimage.median_filter* has a more efficient implementation of a median filter and therefore runs much faster.

For 2-dimensional images with `uint8`, `float32` or `float64` dtypes, the specialised function *scipy.signal.medfilt2d* may be faster.

scipy.signal.medfilt2d

`scipy.signal.`**`medfilt2d`**(*input*, *kernel_size=3*)

Median filter a 2-dimensional array.

Apply a median filter to the *input* array using a local window-size given by *kernel_size* (must be odd). The array is zero-padded automatically.

Parameters

input [array_like] A 2-dimensional input array.

kernel_size [array_like, optional] A scalar or a list of length 2, giving the size of the median filter window in each dimension. Elements of *kernel_size* should be odd. If *kernel_size* is a scalar, then this scalar is used as the size in each dimension. Default is a kernel of size (3, 3).

Returns

out [ndarray] An array the same size as input containing the median filtered result.

See also:

scipy.ndimage.median_filter

Notes

This is faster than *medfilt* when the input dtype is `uint8`, `float32`, or `float64`; for other types, this falls back to *medfilt*; you should use *scipy.ndimage.median_filter* instead as it is much faster. In some situations, *scipy.ndimage.median_filter* may be faster than this function.

scipy.signal.wiener

`scipy.signal.`**`wiener`**(*im*, *mysize=None*, *noise=None*)

Perform a Wiener filter on an N-dimensional array.

Apply a Wiener filter to the N-dimensional array *im*.

Parameters

im [ndarray] An N-dimensional array.

mysize [int or array_like, optional] A scalar or an N-length list giving the size of the Wiener filter window in each dimension. Elements of mysize should be odd. If mysize is a scalar, then this scalar is used as the size in each dimension.

noise [float, optional] The noise-power to use. If None, then noise is estimated as the average of the local variance of the input.

Returns

out [ndarray] Wiener filtered result with the same shape as *im*.

Notes

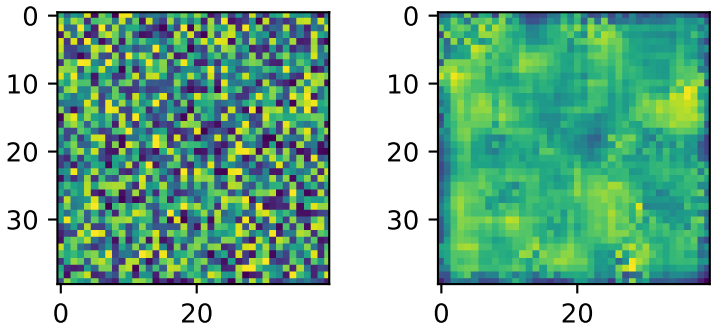
This implementation is similar to wiener2 in Matlab/Octave. For more details see [1]

References

[1]

Examples

```
>>> from scipy.misc import face
>>> from scipy.signal.signaltools import wiener
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> rng = np.random.default_rng()
>>> img = rng.random((40, 40))    #Create a random image
>>> filtered_img = wiener(img, (5, 5))  #Filter the image
>>> f, (plot1, plot2) = plt.subplots(1, 2)
>>> plot1.imshow(img)
>>> plot2.imshow(filtered_img)
>>> plt.show()
```



scipy.signal.symiirorder1

scipy.signal.**symiirorder1**(*input*, *c0*, *z1*, *precision=- 1.0*)

Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of first-order sections. The second section uses a reversed sequence. This implements a system with the following transfer function and mirror-symmetric boundary conditions:

```
                c0
H(z) = ---------------------
        (1-z1/z) (1 - z1 z)
```

The resulting signal will have mirror symmetric boundary conditions as well.

Parameters

input [ndarray] The input signal.
c0, z1 [scalar] Parameters in the transfer function.
precision : Specifies the precision for calculating initial conditions of the recursive filter based on mirror-symmetric input.

Returns

output [ndarray] The filtered signal.

scipy.signal.symiirorder2

scipy.signal.**symiirorder2**(*input*, *r*, *omega*, *precision=- 1.0*)

Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of second-order sections. The second section uses a reversed sequence. This implements the following transfer function:

```
                            cs^2
H(z) = ---------------------------------------
       (1 - a2/z - a3/z^2) (1 - a2 z - a3 z^2 )
```

where:

```
a2 = (2 r cos omega)
a3 = - r^2
cs = 1 - 2 r cos omega + r^2
```

Parameters

input [ndarray] The input signal.
r, omega [float] Parameters in the transfer function.
precision [float] Specifies the precision for calculating initial conditions of the recursive filter based on mirror-symmetric input.

Returns

output [ndarray] The filtered signal.

scipy.signal.lfilter

scipy.signal.**lfilter**(*b*, *a*, *x*, *axis=- 1*, *zi=None*)

Filter data along one-dimension with an IIR or FIR filter.

Filter a data sequence, *x*, using a digital filter. This works for many fundamental data types (including Object type). The filter is a direct form II transposed implementation of the standard difference equation (see Notes).

The function *sosfilt* (and filter design using `output='sos'`) should be preferred over *lfilter* for most filtering tasks, as second-order sections have fewer numerical problems.

Parameters

b	[array_like] The numerator coefficient vector in a 1-D sequence.
a	[array_like] The denominator coefficient vector in a 1-D sequence. If `a[0]` is not 1, then both *a* and *b* are normalized by `a[0]`.
x	[array_like] An N-dimensional input array.
axis	[int, optional] The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.
zi	[array_like, optional] Initial conditions for the filter delays. It is a vector (or array of vectors for an N-dimensional input) of length `max(len(a), len(b)) - 1`. If *zi* is None or is not given then initial rest is assumed. See *lfiltic* for more information.

Returns

y	[array] The output of the digital filter.
zf	[array, optional] If *zi* is None, this is not returned, otherwise, *zf* holds the final filter delay values.

See also:

lfiltic

Construct initial conditions for *lfilter*.

lfilter_zi

Compute initial state (steady state of step response) for *lfilter*.

filtfilt

A forward-backward filter, to obtain a filter with linear phase.

savgol_filter

A Savitzky-Golay filter.

sosfilt

Filter data using cascaded second-order sections.

sosfiltfilt

A forward-backward filter using second-order sections.

Notes

The filter function is implemented as a direct II transposed structure. This means that the filter implements:

```
a[0]*y[n] = b[0]*x[n] + b[1]*x[n-1] + ... + b[M]*x[n-M]
                      - a[1]*y[n-1] - ... - a[N]*y[n-N]
```

where *M* is the degree of the numerator, *N* is the degree of the denominator, and *n* is the sample number. It is implemented using the following difference equations (assuming M = N):

```
a[0]*y[n] = b[0] * x[n]                 + d[0][n-1]
  d[0][n] = b[1] * x[n] - a[1] * y[n] + d[1][n-1]
  d[1][n] = b[2] * x[n] - a[2] * y[n] + d[2][n-1]
...
d[N-2][n] = b[N-1]*x[n] - a[N-1]*y[n] + d[N-1][n-1]
d[N-1][n] = b[N] * x[n] - a[N] * y[n]
```

where *d* are the state variables.

The rational transfer function describing this filter in the z-transform domain is:

```
                     -1              -M
        b[0] + b[1]z  + ... + b[M] z
Y(z) = -------------------------------- X(z)
                     -1              -N
        a[0] + a[1]z  + ... + a[N] z
```

Examples

Generate a noisy signal to be filtered:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> t = np.linspace(-1, 1, 201)
>>> x = (np.sin(2*np.pi*0.75*t*(1-t) + 2.1) +
...      0.1*np.sin(2*np.pi*1.25*t + 1) +
...      0.18*np.cos(2*np.pi*3.85*t))
>>> xn = x + rng.standard_normal(len(t)) * 0.08
```

Create an order 3 lowpass butterworth filter:

```
>>> b, a = signal.butter(3, 0.05)
```

Apply the filter to xn. Use lfilter_zi to choose the initial condition of the filter:

```
>>> zi = signal.lfilter_zi(b, a)
>>> z, _ = signal.lfilter(b, a, xn, zi=zi*xn[0])
```

Apply the filter again, to have a result filtered at an order the same as filtfilt:

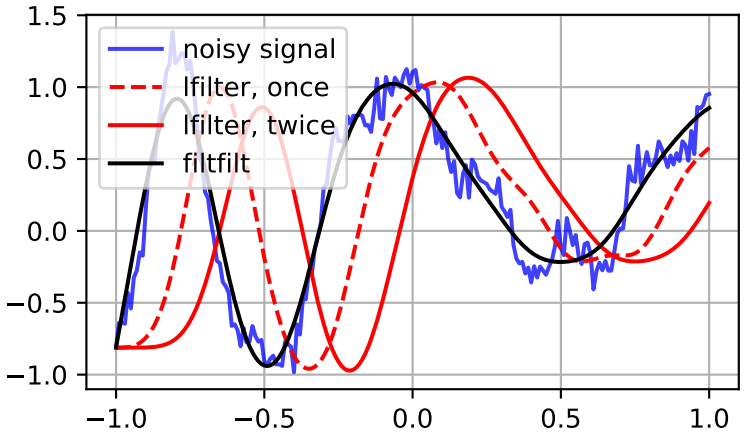
```
>>> z2, _ = signal.lfilter(b, a, z, zi=zi*z[0])
```

Use filtfilt to apply the filter:

```
>>> y = signal.filtfilt(b, a, xn)
```

Plot the original signal and the various filtered versions:

```
>>> plt.figure
>>> plt.plot(t, xn, 'b', alpha=0.75)
>>> plt.plot(t, z, 'r--', t, z2, 'r', t, y, 'k')
>>> plt.legend(('noisy signal', 'lfilter, once', 'lfilter, twice',
...             'filtfilt'), loc='best')
>>> plt.grid(True)
>>> plt.show()
```



scipy.signal.lfiltic

scipy.signal.**lfiltic**(*b*, *a*, *y*, *x=None*)

Construct initial conditions for lfilter given input and output vectors.

Given a linear filter (b, a) and initial conditions on the output *y* and the input *x*, return the initial conditions on the state vector zi which is used by `lfilter` to generate the output given the input.

Parameters

b [array_like] Linear filter term.

a [array_like] Linear filter term.

y [array_like] Initial conditions.
If `N = len(a) - 1`, then `y = {y[-1], y[-2], ..., y[-N]}`.
If *y* is too short, it is padded with zeros.

x [array_like, optional] Initial conditions.
If `M = len(b) - 1`, then `x = {x[-1], x[-2], ..., x[-M]}`.
If *x* is not given, its initial conditions are assumed zero.
If *x* is too short, it is padded with zeros.

Returns

zi [ndarray] The state vector `zi = {z_0[-1], z_1[-1], ..., z_K-1[-1]}`, where `K = max(M, N)`.

See also:

`lfilter`, `lfilter_zi`

scipy.signal.lfilter_zi

scipy.signal.**lfilter_zi**(*b*, *a*)

Construct initial conditions for lfilter for step response steady-state.

Compute an initial state *zi* for the *lfilter* function that corresponds to the steady state of the step response.

A typical use of this function is to set the initial state so that the output of the filter starts at the same value as the first element of the signal to be filtered.

Parameters

b, a [array_like (1-D)] The IIR filter coefficients. See *lfilter* for more information.

Returns

zi [1-D ndarray] The initial state for the filter.

See also:

`lfilter`, `lfiltic`, `filtfilt`

Notes

A linear filter with order m has a state space representation (A, B, C, D), for which the output y of the filter can be expressed as:

```
z(n+1) = A*z(n) + B*x(n)
y(n)   = C*z(n) + D*x(n)
```

where z(n) is a vector of length m, A has shape (m, m), B has shape (m, 1), C has shape (1, m) and D has shape (1, 1) (assuming x(n) is a scalar). lfilter_zi solves:

```
zi = A*zi + B
```

In other words, it finds the initial condition for which the response to an input of all ones is a constant.

Given the filter coefficients *a* and *b*, the state space matrices for the transposed direct form II implementation of the linear filter, which is the implementation used by scipy.signal.lfilter, are:

```
A = scipy.linalg.companion(a).T
B = b[1:] - a[1:]*b[0]
```

assuming *a[0]* is 1.0; if *a[0]* is not 1, *a* and *b* are first divided by a[0].

Examples

The following code creates a lowpass Butterworth filter. Then it applies that filter to an array whose values are all 1.0; the output is also all 1.0, as expected for a lowpass filter. If the *zi* argument of `lfilter` had not been given, the output would have shown the transient signal.

```
>>> from numpy import array, ones
>>> from scipy.signal import lfilter, lfilter_zi, butter
>>> b, a = butter(5, 0.25)
>>> zi = lfilter_zi(b, a)
>>> y, zo = lfilter(b, a, ones(10), zi=zi)
>>> y
array([1.,  1.,  1.,  1.,  1.,  1.,  1.,  1.,  1.,  1.])
```

Another example:

```
>>> x = array([0.5, 0.5, 0.5, 0.0, 0.0, 0.0, 0.0])
>>> y, zf = lfilter(b, a, x, zi=zi*x[0])
>>> y
array([ 0.5       ,  0.5       ,  0.5       ,  0.49836039,  0.48610528,
    0.44399389,  0.35505241])
```

Note that the *zi* argument to `lfilter` was computed using `lfilter_zi` and scaled by *x[0]*. Then the output *y* has no transient until the input drops from 0.5 to 0.0.

scipy.signal.filtfilt

`scipy.signal.`**`filtfilt`**(*b*, *a*, *x*, *axis=- 1*, *padtype='odd'*, *padlen=None*, *method='pad'*, *irlen=None*)

Apply a digital filter forward and backward to a signal.

This function applies a linear digital filter twice, once forward and once backwards. The combined filter has zero phase and a filter order twice that of the original.

The function provides options for handling the edges of the signal.

The function `sosfiltfilt` (and filter design using `output='sos'`) should be preferred over `filtfilt` for most filtering tasks, as second-order sections have fewer numerical problems.

Parameters

b	[(N,) array_like] The numerator coefficient vector of the filter.
a	[(N,) array_like] The denominator coefficient vector of the filter. If `a[0]` is not 1, then both *a* and *b* are normalized by `a[0]`.
x	[array_like] The array of data to be filtered.
axis	[int, optional] The axis of *x* to which the filter is applied. Default is -1.
padtype	[str or None, optional] Must be 'odd', 'even', 'constant', or None. This determines the type of extension to use for the padded signal to which the filter is applied. If *padtype* is None, no padding is used. The default is 'odd'.
padlen	[int or None, optional] The number of elements by which to extend *x* at both ends of *axis* before applying the filter. This value must be less than `x.shape[axis] - 1`. `padlen=0` implies no padding. The default value is `3 * max(len(a), len(b))`.
method	[str, optional] Determines the method for handling the edges of the signal, either "pad" or "gust". When *method* is "pad", the signal is padded; the type of padding is determined by *padtype* and *padlen*, and *irlen* is ignored. When *method* is "gust", Gustafsson's method is used, and *padtype* and *padlen* are ignored.

irlen [int or None, optional] When *method* is "gust", *irlen* specifies the length of the impulse response of the filter. If *irlen* is None, no part of the impulse response is ignored. For a long signal, specifying *irlen* can significantly improve the performance of the filter.

Returns

y [ndarray] The filtered output with the same shape as *x*.

See also:

`sosfiltfilt`, `lfilter_zi`, `lfilter`, `lfiltic`, `savgol_filter`, `sosfilt`

Notes

When *method* is "pad", the function pads the data along the given axis in one of three ways: odd, even or constant. The odd and even extensions have the corresponding symmetry about the end point of the data. The constant extension extends the data with the values at the end points. On both the forward and backward passes, the initial condition of the filter is found by using *lfilter_zi* and scaling it by the end point of the extended data.

When *method* is "gust", Gustafsson's method [1] is used. Initial conditions are chosen for the forward and backward passes so that the forward-backward filter gives the same result as the backward-forward filter.

The option to use Gustaffson's method was added in scipy version 0.16.0.

References

[1]

Examples

The examples will use several functions from *scipy.signal*.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

First we create a one second signal that is the sum of two pure sine waves, with frequencies 5 Hz and 250 Hz, sampled at 2000 Hz.

```
>>> t = np.linspace(0, 1.0, 2001)
>>> xlow = np.sin(2 * np.pi * 5 * t)
>>> xhigh = np.sin(2 * np.pi * 250 * t)
>>> x = xlow + xhigh
```

Now create a lowpass Butterworth filter with a cutoff of 0.125 times the Nyquist frequency, or 125 Hz, and apply it to `x` with *filtfilt*. The result should be approximately `xlow`, with no phase shift.

```
>>> b, a = signal.butter(8, 0.125)
>>> y = signal.filtfilt(b, a, x, padlen=150)
>>> np.abs(y - xlow).max()
9.1086182074789912e-06
```

We get a fairly clean result for this artificial example because the odd extension is exact, and with the moderately long padding, the filter's transients have dissipated by the time the actual data is reached. In general, transient effects at the edges are unavoidable.

The following example demonstrates the option `method="gust"`.

First, create a filter.

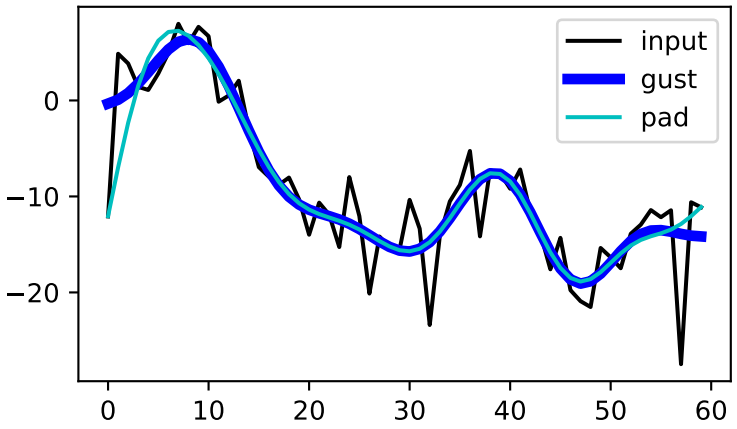
```
>>> b, a = signal.ellip(4, 0.01, 120, 0.125)  # Filter to be applied.
```

sig is a random input signal to be filtered.

```
>>> rng = np.random.default_rng()
>>> n = 60
>>> sig = rng.standard_normal(n)**3 + 3*rng.standard_normal(n).cumsum()
```

Apply *filtfilt* to *sig*, once using the Gustafsson method, and once using padding, and plot the results for comparison.

```
>>> fgust = signal.filtfilt(b, a, sig, method="gust")
>>> fpad = signal.filtfilt(b, a, sig, padlen=50)
>>> plt.plot(sig, 'k-', label='input')
>>> plt.plot(fgust, 'b-', linewidth=4, label='gust')
>>> plt.plot(fpad, 'c-', linewidth=1.5, label='pad')
>>> plt.legend(loc='best')
>>> plt.show()
```



The *irlen* argument can be used to improve the performance of Gustafsson's method.

Estimate the impulse response length of the filter.

```
>>> z, p, k = signal.tf2zpk(b, a)
>>> eps = 1e-9
>>> r = np.max(np.abs(p))
>>> approx_impulse_len = int(np.ceil(np.log(eps) / np.log(r)))
>>> approx_impulse_len
137
```

Apply the filter to a longer signal, with and without the *irlen* argument. The difference between *y1* and *y2* is small. For long signals, using *irlen* gives a significant performance improvement.

```
>>> x = rng.standard_normal(5000)
>>> y1 = signal.filtfilt(b, a, x, method='gust')
>>> y2 = signal.filtfilt(b, a, x, method='gust', irlen=approx_impulse_len)
>>> print(np.max(np.abs(y1 - y2)))
1.80056858312e-10
```

scipy.signal.savgol_filter

scipy.signal.**savgol_filter**(*x*, *window_length*, *polyorder*, *deriv=0*, *delta=1.0*, *axis=- 1*, *mode='interp'*, *cval=0.0*)

Apply a Savitzky-Golay filter to an array.

This is a 1-D filter. If *x* has dimension greater than 1, *axis* determines the axis along which the filter is applied.

Parameters

x [array_like] The data to be filtered. If *x* is not a single or double precision floating point array, it will be converted to type `numpy.float64` before filtering.

window_length [int] The length of the filter window (i.e., the number of coefficients). *window_length* must be a positive odd integer. If *mode* is 'interp', *window_length* must be less than or equal to the size of *x*.

polyorder [int] The order of the polynomial used to fit the samples. *polyorder* must be less than *window_length*.

deriv [int, optional] The order of the derivative to compute. This must be a nonnegative integer. The default is 0, which means to filter the data without differentiating.

delta [float, optional] The spacing of the samples to which the filter will be applied. This is only used if deriv > 0. Default is 1.0.

axis [int, optional] The axis of the array *x* along which the filter is to be applied. Default is -1.

mode [str, optional] Must be 'mirror', 'constant', 'nearest', 'wrap' or 'interp'. This determines the type of extension to use for the padded signal to which the filter is applied. When *mode* is 'constant', the padding value is given by *cval*. See the Notes for more details on 'mirror', 'constant', 'wrap', and 'nearest'. When the 'interp' mode is selected (the default), no extension is used. Instead, a degree *polyorder* polynomial is fit to the last *window_length* values of the edges, and this polynomial is used to evaluate the last *window_length // 2* output values.

cval [scalar, optional] Value to fill past the edges of the input if *mode* is 'constant'. Default is 0.0.

Returns

y [ndarray, same shape as *x*] The filtered data.

See also:

`savgol_coeffs`

Notes

Details on the *mode* options:

'mirror':
Repeats the values at the edges in reverse order. The value closest to the edge is not included.

'nearest':
The extension contains the nearest input value.

'constant':
The extension contains the value given by the *cval* argument.

'wrap':
The extension contains the values from the other end of the array.

For example, if the input is [1, 2, 3, 4, 5, 6, 7, 8], and *window_length* is 7, the following shows the extended data for the various *mode* options (assuming *cval* is 0):

```
mode        |   Ext   |         Input          |   Ext
------------+---------+------------------------+---------
'mirror'    | 4  3  2 | 1  2  3  4  5  6  7  8 | 7  6  5
'nearest'   | 1  1  1 | 1  2  3  4  5  6  7  8 | 8  8  8
'constant'  | 0  0  0 | 1  2  3  4  5  6  7  8 | 0  0  0
'wrap'      | 6  7  8 | 1  2  3  4  5  6  7  8 | 1  2  3
```

New in version 0.14.0.

Examples

```
>>> from scipy.signal import savgol_filter
>>> np.set_printoptions(precision=2)  # For compact display.
>>> x = np.array([2, 2, 5, 2, 1, 0, 1, 4, 9])
```

Filter with a window length of 5 and a degree 2 polynomial. Use the defaults for all other parameters.

```
>>> savgol_filter(x, 5, 2)
array([1.66, 3.17, 3.54, 2.86, 0.66, 0.17, 1.  , 4.  , 9.  ])
```

Note that the last five values in x are samples of a parabola, so when mode='interp' (the default) is used with polyorder=2, the last three values are unchanged. Compare that to, for example, *mode='nearest'*:

```
>>> savgol_filter(x, 5, 2, mode='nearest')
array([1.74, 3.03, 3.54, 2.86, 0.66, 0.17, 1.  , 4.6 , 7.97])
```

scipy.signal.deconvolve

`scipy.signal.`**`deconvolve`**(*signal*, *divisor*)

Deconvolves `divisor` out of `signal` using inverse filtering.

Returns the quotient and remainder such that `signal = convolve(divisor, quotient) + remainder`

Parameters

signal	[array_like] Signal data, typically a recorded signal
divisor	[array_like] Divisor data, typically an impulse response or filter that was applied to the original signal

Returns

quotient	[ndarray] Quotient, typically the recovered original signal
remainder	[ndarray] Remainder

See also:

`numpy.polydiv`

performs polynomial division (same operation, but also accepts poly1d objects)

Examples

Deconvolve a signal that's been filtered:

```
>>> from scipy import signal
>>> original = [0, 1, 0, 0, 1, 1, 0, 0]
>>> impulse_response = [2, 1]
>>> recorded = signal.convolve(impulse_response, original)
>>> recorded
array([0, 2, 1, 0, 2, 3, 1, 0, 0])
>>> recovered, remainder = signal.deconvolve(recorded, impulse_response)
>>> recovered
array([ 0.,  1.,  0.,  0.,  1.,  1.,  0.,  0.])
```

scipy.signal.sosfilt

scipy.signal.**sosfilt**(*sos*, *x*, *axis=- 1*, *zi=None*)

Filter data along one dimension using cascaded second-order sections.

Filter a data sequence, *x*, using a digital IIR filter defined by *sos*.

Parameters

sos [array_like] Array of second-order filter coefficients, must have shape `(n_sections, 6)`. Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.

x [array_like] An N-dimensional input array.

axis [int, optional] The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.

zi [array_like, optional] Initial conditions for the cascaded filter delays. It is a (at least 2D) vector of shape `(n_sections, ..., 2, ...)`, where `..., 2, ...` denotes the shape of *x*, but with `x.shape[axis]` replaced by 2. If *zi* is None or is not given then initial rest (i.e. all zeros) is assumed. Note that these initial conditions are *not* the same as the initial conditions given by *lfiltic* or *lfilter_zi*.

Returns

y [ndarray] The output of the digital filter.

zf [ndarray, optional] If *zi* is None, this is not returned, otherwise, *zf* holds the final filter delay values.

See also:

zpk2sos, **sos2zpk**, **sosfilt_zi**, **sosfiltfilt**, **sosfreqz**

Notes

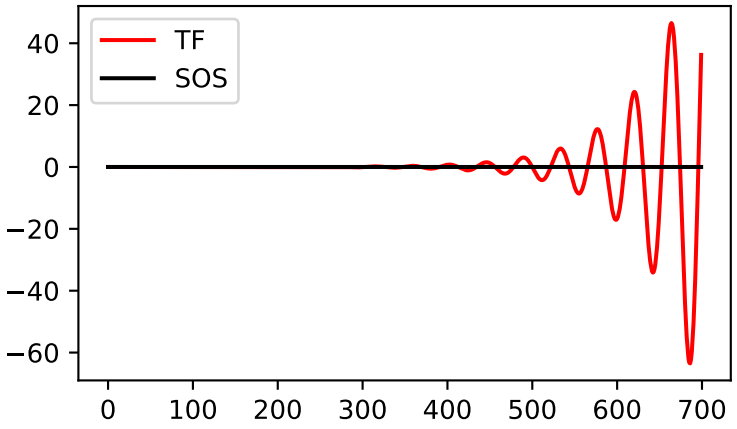
The filter function is implemented as a series of second-order filters with direct-form II transposed structure. It is designed to minimize numerical precision errors for high-order filters.

New in version 0.16.0.

Examples

Plot a 13th-order filter's impulse response using both *lfilter* and *sosfilt*, showing the instability that results from trying to do a 13th-order filter in a single stage (the numerical error pushes some poles outside of the unit circle):

```
>>> import matplotlib.pyplot as plt
>>> from scipy import signal
>>> b, a = signal.ellip(13, 0.009, 80, 0.05, output='ba')
>>> sos = signal.ellip(13, 0.009, 80, 0.05, output='sos')
>>> x = signal.unit_impulse(700)
>>> y_tf = signal.lfilter(b, a, x)
>>> y_sos = signal.sosfilt(sos, x)
>>> plt.plot(y_tf, 'r', label='TF')
>>> plt.plot(y_sos, 'k', label='SOS')
>>> plt.legend(loc='best')
>>> plt.show()
```



scipy.signal.sosfilt_zi

scipy.signal.**sosfilt_zi**(*sos*)

Construct initial conditions for sosfilt for step response steady-state.

Compute an initial state *zi* for the *sosfilt* function that corresponds to the steady state of the step response.

A typical use of this function is to set the initial state so that the output of the filter starts at the same value as the first element of the signal to be filtered.

Parameters

sos [array_like] Array of second-order filter coefficients, must have shape `(n_sections, 6)`. See *sosfilt* for the SOS filter format specification.

Returns

zi [ndarray] Initial conditions suitable for use with `sosfilt`, shape `(n_sections, 2)`.

See also:

sosfilt, **zpk2sos**

Notes

New in version 0.16.0.

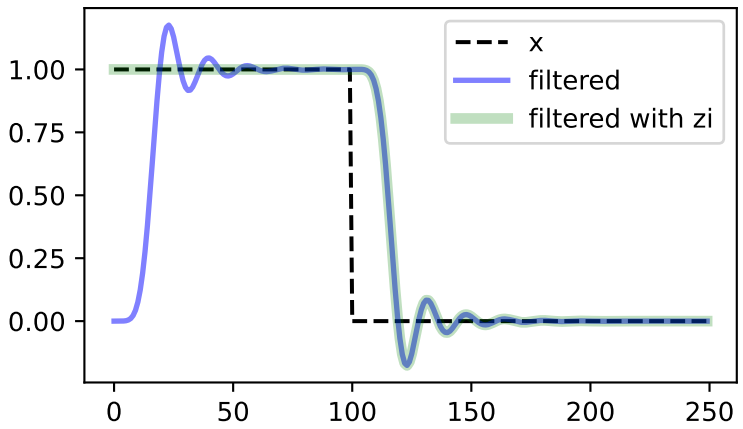
Examples

Filter a rectangular pulse that begins at time 0, with and without the use of the *zi* argument of *scipy.signal.sosfilt*.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> sos = signal.butter(9, 0.125, output='sos')
>>> zi = signal.sosfilt_zi(sos)
>>> x = (np.arange(250) < 100).astype(int)
>>> f1 = signal.sosfilt(sos, x)
>>> f2, zo = signal.sosfilt(sos, x, zi=zi)
```

```
>>> plt.plot(x, 'k--', label='x')
>>> plt.plot(f1, 'b', alpha=0.5, linewidth=2, label='filtered')
>>> plt.plot(f2, 'g', alpha=0.25, linewidth=4, label='filtered with zi')
>>> plt.legend(loc='best')
>>> plt.show()
```



scipy.signal.sosfiltfilt

scipy.signal.**sosfiltfilt**(*sos*, *x*, *axis=- 1*, *padtype='odd'*, *padlen=None*)

A forward-backward digital filter using cascaded second-order sections.

See *filtfilt* for more complete information about this method.

Parameters

sos [array_like] Array of second-order filter coefficients, must have shape `(n_sections, 6)`. Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.

x [array_like] The array of data to be filtered.

axis [int, optional] The axis of *x* to which the filter is applied. Default is -1.

padtype [str or None, optional] Must be 'odd', 'even', 'constant', or None. This determines the type of extension to use for the padded signal to which the filter is applied. If *padtype* is None, no padding is used. The default is 'odd'.

padlen [int or None, optional] The number of elements by which to extend *x* at both ends of *axis* before applying the filter. This value must be less than `x.shape[axis] - 1`. `padlen=0` implies no padding. The default value is:

```
3 * (2 * len(sos) + 1 - min((sos[:, 2] == 0).sum(),
                            (sos[:, 5] == 0).sum()))
```

The extra subtraction at the end attempts to compensate for poles and zeros at the origin (e.g. for odd-order filters) to yield equivalent estimates of *padlen* to those of *filtfilt* for second-order section filters built with *scipy.signal* functions.

Returns

y [ndarray] The filtered output with the same shape as *x*.

See also:

filtfilt, **sosfilt**, **sosfilt_zi**, **sosfreqz**

Notes

New in version 0.18.0.

Examples

```
>>> from scipy.signal import sosfiltfilt, butter
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
```

Create an interesting signal to filter.

```
>>> n = 201
>>> t = np.linspace(0, 1, n)
>>> x = 1 + (t < 0.5) - 0.25*t**2 + 0.05*rng.standard_normal(n)
```

Create a lowpass Butterworth filter, and use it to filter *x*.

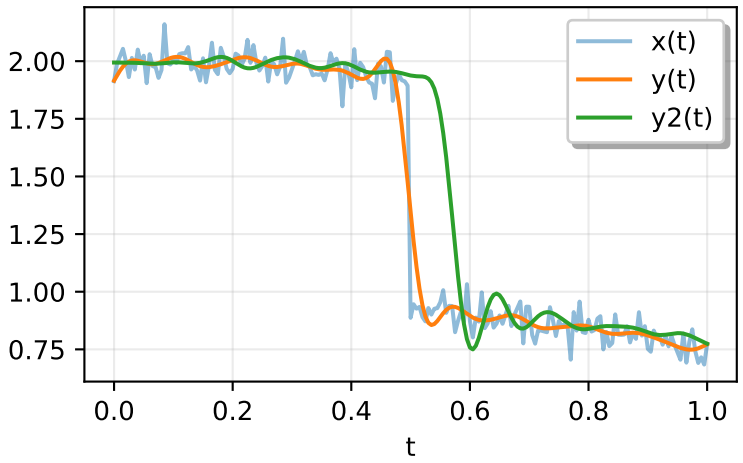
```
>>> sos = butter(4, 0.125, output='sos')
>>> y = sosfiltfilt(sos, x)
```

For comparison, apply an 8th order filter using *sosfilt*. The filter is initialized using the mean of the first four values of *x*.

```
>>> from scipy.signal import sosfilt, sosfilt_zi
>>> sos8 = butter(8, 0.125, output='sos')
>>> zi = x[:4].mean() * sosfilt_zi(sos8)
>>> y2, zo = sosfilt(sos8, x, zi=zi)
```

Plot the results. Note that the phase of *y* matches the input, while *y2* has a significant phase delay.

```
>>> plt.plot(t, x, alpha=0.5, label='x(t)')
>>> plt.plot(t, y, label='y(t)')
>>> plt.plot(t, y2, label='y2(t)')
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.grid(alpha=0.25)
>>> plt.xlabel('t')
>>> plt.show()
```



scipy.signal.hilbert

scipy.signal.**hilbert**(*x*, *N=None*, *axis=- 1*)

Compute the analytic signal, using the Hilbert transform.

The transformation is done along the last axis by default.

Parameters

x	[array_like] Signal data. Must be real.
N	[int, optional] Number of Fourier components. Default: `x.shape[axis]`
axis	[int, optional] Axis along which to do the transformation. Default: -1.

Returns

xa	[ndarray] Analytic signal of *x*, of each 1-D array along *axis*

Notes

The analytic signal `x_a(t)` of signal `x(t)` is:

$$x_a = F^{-1}(F(x)2U) = x + iy$$

where F is the Fourier transform, U the unit step function, and y the Hilbert transform of x. [1]

In other words, the negative half of the frequency spectrum is zeroed out, turning the real-valued signal into a complex signal. The Hilbert transformed signal can be obtained from `np.imag(hilbert(x))`, and the original signal from `np.real(hilbert(x))`.

References

[1], [2], [3]

Examples

In this example we use the Hilbert transform to determine the amplitude envelope and instantaneous frequency of an amplitude-modulated signal.

```
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import hilbert, chirp
```

```
>>> duration = 1.0
>>> fs = 400.0
>>> samples = int(fs*duration)
>>> t = np.arange(samples) / fs
```

We create a chirp of which the frequency increases from 20 Hz to 100 Hz and apply an amplitude modulation.

```
>>> signal = chirp(t, 20.0, t[-1], 100.0)
>>> signal *= (1.0 + 0.5 * np.sin(2.0*np.pi*3.0*t) )
```

The amplitude envelope is given by magnitude of the analytic signal. The instantaneous frequency can be obtained by differentiating the instantaneous phase in respect to time. The instantaneous phase corresponds to the phase angle of the analytic signal.

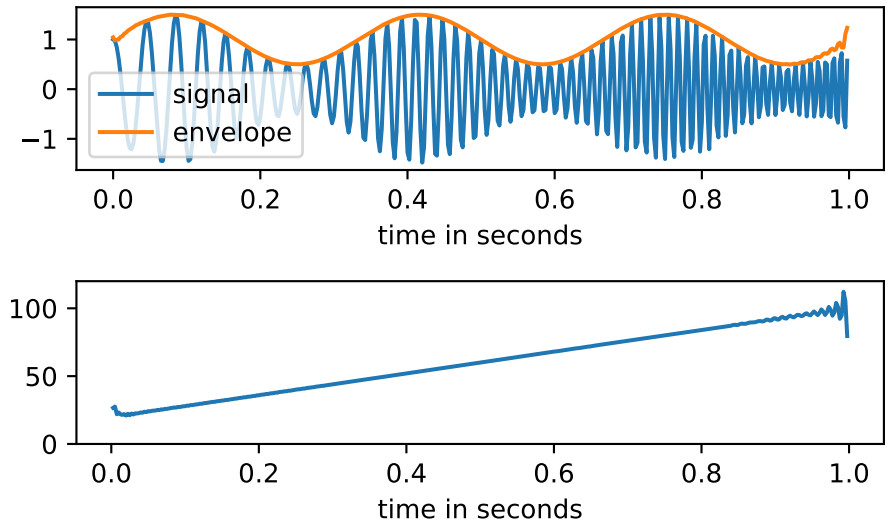
```
>>> analytic_signal = hilbert(signal)
>>> amplitude_envelope = np.abs(analytic_signal)
>>> instantaneous_phase = np.unwrap(np.angle(analytic_signal))
>>> instantaneous_frequency = (np.diff(instantaneous_phase) /
...                            (2.0*np.pi) * fs)
```

```
>>> fig, (ax0, ax1) = plt.subplots(nrows=2)
>>> ax0.plot(t, signal, label='signal')
>>> ax0.plot(t, amplitude_envelope, label='envelope')
>>> ax0.set_xlabel("time in seconds")
>>> ax0.legend()
>>> ax1.plot(t[1:], instantaneous_frequency)
>>> ax1.set_xlabel("time in seconds")
```

(continues on next page)

(continued from previous page)

```
>>> ax1.set_ylim(0.0, 120.0)
>>> fig.tight_layout()
```



scipy.signal.hilbert2

`scipy.signal.`**`hilbert2`**(*x*, *N=None*)

Compute the '2-D' analytic signal of *x*

Parameters

x	[array_like] 2-D signal data.
N	[int or tuple of two ints, optional] Number of Fourier components. Default is `x.shape`

Returns

xa	[ndarray] Analytic signal of *x* taken along axes (0,1).

References

[1]

scipy.signal.decimate

`scipy.signal.`**`decimate`**(*x*, *q*, *n=None*, *ftype='iir'*, *axis=- 1*, *zero_phase=True*)

Downsample the signal after applying an anti-aliasing filter.

By default, an order 8 Chebyshev type I filter is used. A 30 point FIR filter with Hamming window is used if *ftype* is 'fir'.

Parameters

x	[array_like] The signal to be downsampled, as an N-dimensional array.
q	[int] The downsampling factor. When using IIR downsampling, it is recommended to call *decimate* multiple times for downsampling factors higher than 13.
n	[int, optional] The order of the filter (1 less than the length for 'fir'). Defaults to 8 for 'iir' and 20 times the downsampling factor for 'fir'.

ftype [str {'iir', 'fir'} or `dlti` instance, optional] If 'iir' or 'fir', specifies the type of lowpass filter. If an instance of an *dlti* object, uses that object to filter before downsampling.

axis [int, optional] The axis along which to decimate.

zero_phase
[bool, optional] Prevent phase shift by filtering with *filtfilt* instead of *lfilter* when using an IIR filter, and shifting the outputs back by the filter's group delay when using an FIR filter. The default value of `True` is recommended, since a phase shift is generally not desired.
New in version 0.18.0.

Returns

y [ndarray] The down-sampled signal.

See also:

resample

Resample up or down using the FFT method.

resample_poly

Resample using polyphase filtering and an FIR filter.

Notes

The `zero_phase` keyword was added in 0.18.0. The possibility to use instances of `dlti` as `ftype` was added in 0.18.0.

scipy.signal.detrend

`scipy.signal.`**`detrend`**(*data*, *axis=-1*, *type='linear'*, *bp=0*, *overwrite_data=False*)

Remove linear trend along axis from data.

Parameters

data [array_like] The input data.

axis [int, optional] The axis along which to detrend the data. By default this is the last axis (-1).

type [{'linear', 'constant'}, optional] The type of detrending. If `type == 'linear'` (default), the result of a linear least-squares fit to *data* is subtracted from *data*. If `type == 'constant'`, only the mean of *data* is subtracted.

bp [array_like of ints, optional] A sequence of break points. If given, an individual linear fit is performed for each part of *data* between two break points. Break points are specified as indices into *data*. This parameter only has an effect when `type == 'linear'`.

overwrite_data
[bool, optional] If True, perform in place detrending and avoid a copy. Default is False

Returns

ret [ndarray] The detrended input data.

Examples

```
>>> from scipy import signal
>>> from numpy.random import default_rng
>>> rng = default_rng()
>>> npoints = 1000
>>> noise = rng.standard_normal(npoints)
>>> x = 3 + 2*np.linspace(0, 1, npoints) + noise
>>> (signal.detrend(x) - noise).max()
0.06  # random
```

scipy.signal.resample

scipy.signal.**resample**(*x*, *num*, *t=None*, *axis=0*, *window=None*, *domain='time'*)

Resample *x* to *num* samples using Fourier method along the given axis.

The resampled signal starts at the same value as *x* but is sampled with a spacing of `len(x) / num * (spacing of x)`. Because a Fourier method is used, the signal is assumed to be periodic.

Parameters

x	[array_like] The data to be resampled.
num	[int] The number of samples in the resampled signal.
t	[array_like, optional] If *t* is given, it is assumed to be the equally spaced sample positions associated with the signal data in *x*.
axis	[int, optional] The axis of *x* that is resampled. Default is 0.
window	[array_like, callable, string, float, or tuple, optional] Specifies the window applied to the signal in the Fourier domain. See below for details.
domain	[string, optional] A string indicating the domain of the input *x*: `time` Consider the input *x* as time-domain (Default), `freq` Consider the input *x* as frequency-domain.

Returns

resampled_x or (resampled_x, resampled_t)
: Either the resampled array, or, if *t* was given, a tuple containing the resampled array and the corresponding resampled positions.

See also:

decimate

Downsample the signal after applying an FIR or IIR filter.

resample_poly

Resample using polyphase filtering and an FIR filter.

Notes

The argument *window* controls a Fourier-domain window that tapers the Fourier spectrum before zero-padding to alleviate ringing in the resampled values for sampled signals you didn't intend to be interpreted as band-limited.

If *window* is a function, then it is called with a vector of inputs indicating the frequency bins (i.e. fftfreq(x.shape[axis])).

If *window* is an array of the same length as *x.shape[axis]* it is assumed to be the window to be applied directly in the Fourier domain (with dc and low-frequency first).

For any other type of *window*, the function *scipy.signal.get_window* is called to generate the window.

The first sample of the returned vector is the same as the first sample of the input vector. The spacing between samples is changed from `dx` to `dx * len(x) / num`.

If *t* is not None, then it is used solely to calculate the resampled positions *resampled_t*

As noted, *resample* uses FFT transformations, which can be very slow if the number of input or output samples is large and prime; see *scipy.fft.fft*.

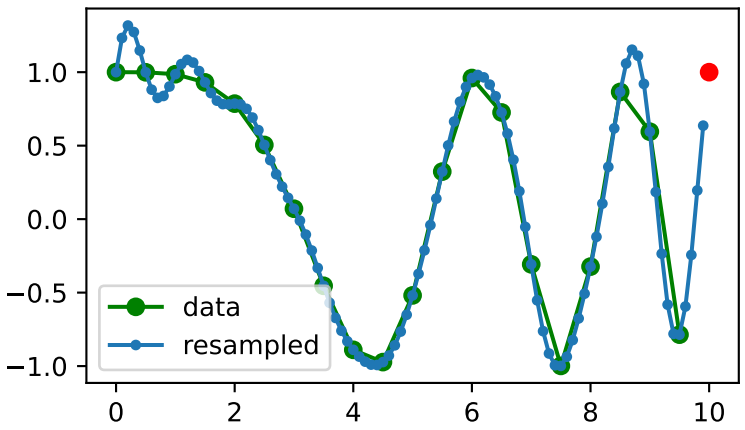
Examples

Note that the end of the resampled data rises to meet the first sample of the next cycle:

```
>>> from scipy import signal
```

```
>>> x = np.linspace(0, 10, 20, endpoint=False)
>>> y = np.cos(-x**2/6.0)
>>> f = signal.resample(y, 100)
>>> xnew = np.linspace(0, 10, 100, endpoint=False)
```

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'go-', xnew, f, '.-', 10, y[0], 'ro')
>>> plt.legend(['data', 'resampled'], loc='best')
>>> plt.show()
```



scipy.signal.resample_poly

scipy.signal.**resample_poly**(*x*, *up*, *down*, *axis=0*, *window=('kaiser', 5.0)*, *padtype='constant'*, *cval=None*)

Resample *x* along the given axis using polyphase filtering.

The signal *x* is upsampled by the factor *up*, a zero-phase low-pass FIR filter is applied, and then it is downsampled by the factor *down*. The resulting sample rate is `up / down` times the original sample rate. By default, values beyond the boundary of the signal are assumed to be zero during the filtering step.

Parameters

x [array_like] The data to be resampled.
up [int] The upsampling factor.
down [int] The downsampling factor.
axis [int, optional] The axis of *x* that is resampled. Default is 0.
window [string, tuple, or array_like, optional] Desired window to use to design the low-pass filter, or the FIR filter coefficients to employ. See below for details.
padtype [string, optional] *constant*, *line*, *mean*, *median*, *maximum*, *minimum* or any of the other signal extension modes supported by `scipy.signal.upfirdn`. Changes assumptions on values beyond the boundary. If *constant*, assumed to be *cval* (default zero). If *line* assumed to continue a linear trend defined by the first and last points. *mean*, *median*, *maximum* and *minimum* work as in *np.pad* and assume that the values beyond the boundary are the mean, median, maximum or minimum respectively of the array along the axis.
New in version 1.4.0.
cval [float, optional] Value to use if *padtype='constant'*. Default is zero.
New in version 1.4.0.

Returns

resampled_x
[array] The resampled array.

See also:

decimate

Downsample the signal after applying an FIR or IIR filter.

resample

Resample up or down using the FFT method.

Notes

This polyphase method will likely be faster than the Fourier method in `scipy.signal.resample` when the number of samples is large and prime, or when the number of samples is large and *up* and *down* share a large greatest common denominator. The length of the FIR filter used will depend on `max(up, down) // gcd(up, down)`, and the number of operations during polyphase filtering will depend on the filter length and *down* (see `scipy.signal.upfirdn` for details).

The argument *window* specifies the FIR low-pass filter design.

If *window* is an array_like it is assumed to be the FIR filter coefficients. Note that the FIR filter is applied after the upsampling step, so it should be designed to operate on a signal at a sampling frequency higher than the original by a factor of *up//gcd(up, down)*. This function's output will be centered with respect to this array, so it is best to pass a symmetric filter with an odd number of samples if, as is usually the case, a zero-phase filter is desired.

For any other type of *window*, the functions `scipy.signal.get_window` and `scipy.signal.firwin` are called to generate the appropriate filter coefficients.

The first sample of the returned vector is the same as the first sample of the input vector. The spacing between samples is changed from `dx` to `dx * down / float(up)`.

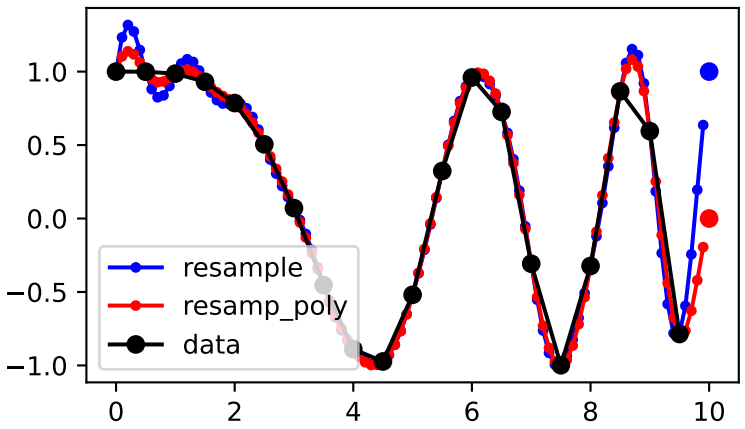
Examples

By default, the end of the resampled data rises to meet the first sample of the next cycle for the FFT method, and gets closer to zero for the polyphase method:

```
>>> from scipy import signal
```

```
>>> x = np.linspace(0, 10, 20, endpoint=False)
>>> y = np.cos(-x**2/6.0)
>>> f_fft = signal.resample(y, 100)
>>> f_poly = signal.resample_poly(y, 100, 20)
>>> xnew = np.linspace(0, 10, 100, endpoint=False)
```

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(xnew, f_fft, 'b.-', xnew, f_poly, 'r.-')
>>> plt.plot(x, y, 'ko-')
>>> plt.plot(10, y[0], 'bo', 10, 0., 'ro')  # boundaries
>>> plt.legend(['resample', 'resamp_poly', 'data'], loc='best')
>>> plt.show()
```



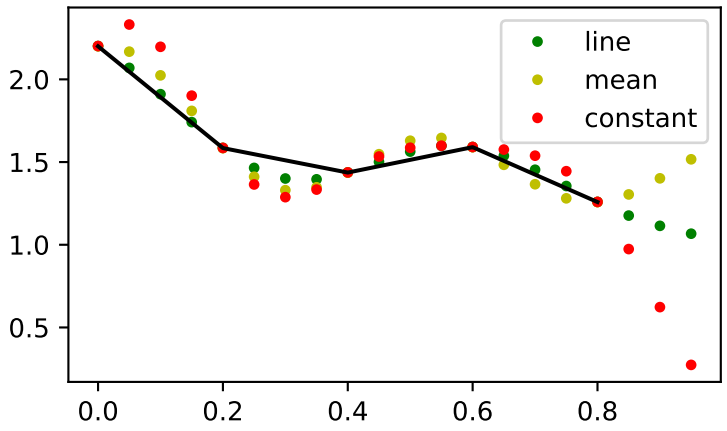
This default behaviour can be changed by using the padtype option:

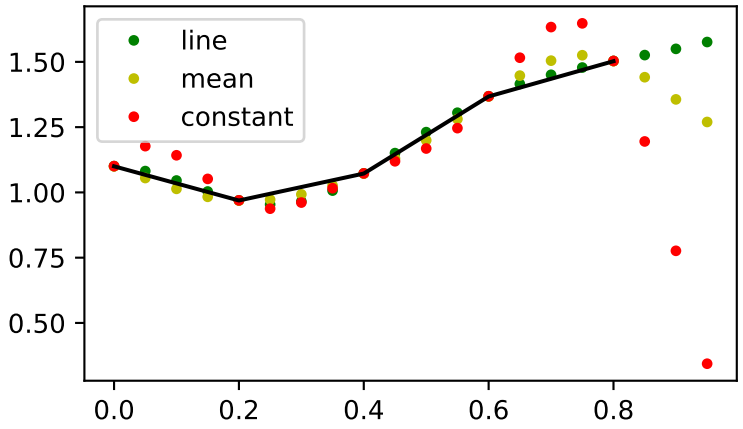
```
>>> import numpy as np
>>> from scipy import signal
```

```
>>> N = 5
>>> x = np.linspace(0, 1, N, endpoint=False)
>>> y = 2 + x**2 - 1.7*np.sin(x) + .2*np.cos(11*x)
>>> y2 = 1 + x**3 + 0.1*np.sin(x) + .1*np.cos(11*x)
>>> Y = np.stack([y, y2], axis=-1)
>>> up = 4
>>> xr = np.linspace(0, 1, N*up, endpoint=False)
```

```
>>> y2 = signal.resample_poly(Y, up, 1, padtype='constant')
>>> y3 = signal.resample_poly(Y, up, 1, padtype='mean')
>>> y4 = signal.resample_poly(Y, up, 1, padtype='line')
```

```
>>> import matplotlib.pyplot as plt
>>> for i in [0,1]:
...     plt.figure()
...     plt.plot(xr, y4[:,i], 'g.', label='line')
...     plt.plot(xr, y3[:,i], 'y.', label='mean')
...     plt.plot(xr, y2[:,i], 'r.', label='constant')
...     plt.plot(x, Y[:,i], 'k-')
...     plt.legend()
>>> plt.show()
```





scipy.signal.upfirdn

scipy.signal.**upfirdn**(*h*, *x*, *up=1*, *down=1*, *axis=- 1*, *mode='constant'*, *cval=0*)

Upsample, FIR filter, and downsample.

Parameters

h [array_like] 1-D FIR (finite-impulse response) filter coefficients.

x [array_like] Input signal array.

up [int, optional] Upsampling rate. Default is 1.

down [int, optional] Downsampling rate. Default is 1.

axis [int, optional] The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.

mode [str, optional] The signal extension mode to use. The set `{"constant", "symmetric", "reflect", "edge", "wrap"}` correspond to modes provided by `numpy.pad`. `"smooth"` implements a smooth extension by extending based on the slope of the last 2 points at each end of the array. `"antireflect"` and `"antisymmetric"` are anti-symmetric versions of `"reflect"` and `"symmetric"`. The mode *"line"* extends the signal based on a linear trend defined by the first and last points along the `axis`.
New in version 1.4.0.

cval [float, optional] The constant value to use when `mode == "constant"`.
New in version 1.4.0.

Returns

y [ndarray] The output signal array. Dimensions will be the same as *x* except for along *axis*, which will change size according to the *h*, *up*, and *down* parameters.

Notes

The algorithm is an implementation of the block diagram shown on page 129 of the Vaidyanathan text [1] (Figure 4.3-8d).

The direct approach of upsampling by factor of P with zero insertion, FIR filtering of length `N`, and downsampling by factor of Q is O(N*Q) per output sample. The polyphase implementation used here is O(N/P).

New in version 0.18.

[1]

Examples

Simple operations:

```
>>> from scipy.signal import upfirdn
>>> upfirdn([1, 1, 1], [1, 1, 1])   # FIR filter
array([ 1.,  2.,  3.,  2.,  1.])
>>> upfirdn([1], [1, 2, 3], 3)  # upsampling with zeros insertion
array([ 1.,  0.,  0.,  2.,  0.,  0.,  3.,  0.,  0.])
>>> upfirdn([1, 1, 1], [1, 2, 3], 3)  # upsampling with sample-and-hold
array([ 1.,  1.,  1.,  2.,  2.,  2.,  3.,  3.,  3.])
```

(continues on next page)

(continued from previous page)

```
>>> upfirdn([.5, 1, .5], [1, 1, 1], 2)  # linear interpolation
array([ 0.5,  1. ,  1. ,  1. ,  1. ,  1. ,  0.5,  0. ])
>>> upfirdn([1], np.arange(10), 1, 3)  # decimation by 3
array([ 0.,  3.,  6.,  9.])
>>> upfirdn([.5, 1, .5], np.arange(10), 2, 3)  # linear interp, rate 2/3
array([ 0. ,  1. ,  2.5,  4. ,  5.5,  7. ,  8.5,  0. ])
```

Apply a single filter to multiple signals:

```
>>> x = np.reshape(np.arange(8), (4, 2))
>>> x
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7]])
```

Apply along the last dimension of `x`:

```
>>> h = [1, 1]
>>> upfirdn(h, x, 2)
array([[ 0.,  0.,  1.,  1.],
       [ 2.,  2.,  3.,  3.],
       [ 4.,  4.,  5.,  5.],
       [ 6.,  6.,  7.,  7.]])
```

Apply along the 0th dimension of `x`:

```
>>> upfirdn(h, x, 2, axis=0)
array([[ 0.,  1.],
       [ 0.,  1.],
       [ 2.,  3.],
       [ 2.,  3.],
       [ 4.,  5.],
       [ 4.,  5.],
       [ 6.,  7.],
       [ 6.,  7.]])
```

Filter design

bilinear(b, a[, fs])	Return a digital IIR filter from an analog one using a bilinear transform.
bilinear_zpk(z, p, k, fs)	Return a digital IIR filter from an analog one using a bilinear transform.
findfreqs(num, den, N[, kind])	Find array of frequencies for computing the response of an analog filter.
firls(numtaps, bands, desired[, weight, nyq, fs])	FIR filter design using least-squares error minimization.
firwin(numtaps, cutoff[, width, window, …])	FIR filter design using the window method.
firwin2(numtaps, freq, gain[, nfreqs, …])	FIR filter design using the window method.
freqs(b, a[, worN, plot])	Compute frequency response of analog filter.
freqs_zpk(z, p, k[, worN])	Compute frequency response of analog filter.

Table 158 – continued from previous page

freqz(b[, a, worN, whole, plot, fs, …])	Compute the frequency response of a digital filter.
freqz_zpk(z, p, k[, worN, whole, fs])	Compute the frequency response of a digital filter in ZPK form.
sosfreqz(sos[, worN, whole, fs])	Compute the frequency response of a digital filter in SOS format.
gammatone(freq, ftype[, order, numtaps, fs])	Gammatone filter design.
group_delay(system[, w, whole, fs])	Compute the group delay of a digital filter.
iirdesign(wp, ws, gpass, gstop[, analog, …])	Complete IIR digital and analog filter design.
iirfilter(N, Wn[, rp, rs, btype, analog, …])	IIR digital and analog filter design given order and critical points.
kaiser_atten(numtaps, width)	Compute the attenuation of a Kaiser FIR filter.
kaiser_beta(a)	Compute the Kaiser parameter *beta*, given the attenuation *a*.
kaiserord(ripple, width)	Determine the filter window parameters for the Kaiser window method.
minimum_phase(h[, method, n_fft])	Convert a linear-phase FIR filter to minimum phase
savgol_coeffs(window_length, polyorder[, …])	Compute the coefficients for a 1-D Savitzky-Golay FIR filter.
remez(numtaps, bands, desired[, weight, Hz, …])	Calculate the minimax optimal filter using the Remez exchange algorithm.
unique_roots(p[, tol, rtype])	Determine unique roots and their multiplicities from a list of roots.
residue(b, a[, tol, rtype])	Compute partial-fraction expansion of b(s) / a(s).
residuez(b, a[, tol, rtype])	Compute partial-fraction expansion of b(z) / a(z).
invres(r, p, k[, tol, rtype])	Compute b(s) and a(s) from partial fraction expansion.
invresz(r, p, k[, tol, rtype])	Compute b(z) and a(z) from partial fraction expansion.
BadCoefficients	Warning about badly conditioned filter coefficients

scipy.signal.bilinear

scipy.signal.**bilinear**(*b*, *a*, *fs=1.0*)

Return a digital IIR filter from an analog one using a bilinear transform.

Transform a set of poles and zeros from the analog s-plane to the digital z-plane using Tustin's method, which substitutes `(z-1) / (z+1)` for `s`, maintaining the shape of the frequency response.

Parameters

b [array_like] Numerator of the analog filter transfer function.

a [array_like] Denominator of the analog filter transfer function.

fs [float] Sample rate, as ordinary frequency (e.g., hertz). No prewarping is done in this function.

Returns

z [ndarray] Numerator of the transformed digital filter transfer function.

p [ndarray] Denominator of the transformed digital filter transfer function.

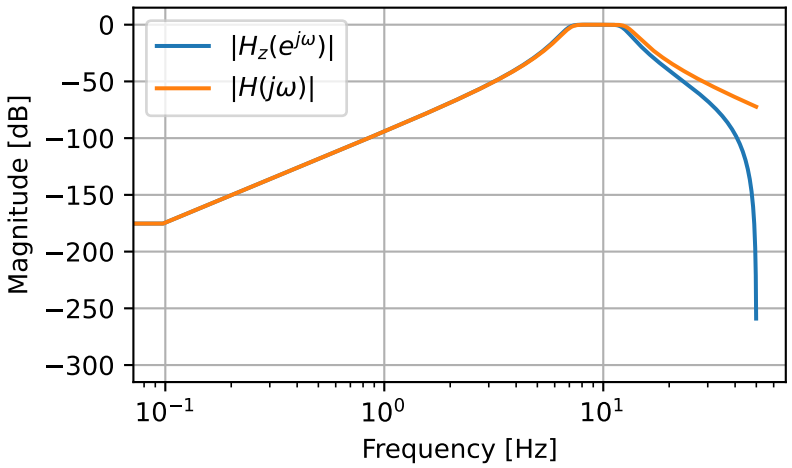
bilinear_zpk

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> fs = 100
>>> bf = 2 * np.pi * np.array([7, 13])
>>> filts = signal.lti(*signal.butter(4, bf, btype='bandpass',
...                                   analog=True))
>>> filtz = signal.lti(*signal.bilinear(filts.num, filts.den, fs))
>>> wz, hz = signal.freqz(filtz.num, filtz.den)
>>> ws, hs = signal.freqs(filts.num, filts.den, worN=fs*wz)
```

```
>>> plt.semilogx(wz*fs/(2*np.pi), 20*np.log10(np.abs(hz).clip(1e-15)),
...              label=r'$|H_z(e^{j \omega})|$')
>>> plt.semilogx(wz*fs/(2*np.pi), 20*np.log10(np.abs(hs).clip(1e-15)),
...              label=r'$|H(j \omega)|$')
>>> plt.legend()
>>> plt.xlabel('Frequency [Hz]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.grid()
```



scipy.signal.bilinear_zpk

`scipy.signal.`**`bilinear_zpk`**(*z*, *p*, *k*, *fs*)

Return a digital IIR filter from an analog one using a bilinear transform.

Transform a set of poles and zeros from the analog s-plane to the digital z-plane using Tustin's method, which substitutes `(z-1) / (z+1)` for `s`, maintaining the shape of the frequency response.

Parameters

z	[array_like] Zeros of the analog filter transfer function.
p	[array_like] Poles of the analog filter transfer function.
k	[float] System gain of the analog filter transfer function.

fs [float] Sample rate, as ordinary frequency (e.g., hertz). No prewarping is done in this function.

Returns

z [ndarray] Zeros of the transformed digital filter transfer function.
p [ndarray] Poles of the transformed digital filter transfer function.
k [float] System gain of the transformed digital filter.

bilinear

Notes

New in version 1.1.0.

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> fs = 100
>>> bf = 2 * np.pi * np.array([7, 13])
>>> filts = signal.lti(*signal.butter(4, bf, btype='bandpass',␣
↪analog=True,
...                                    output='zpk'))
>>> filtz = signal.lti(*signal.bilinear_zpk(filts.zeros, filts.poles,
...                                         filts.gain, fs))
>>> wz, hz = signal.freqz_zpk(filtz.zeros, filtz.poles, filtz.gain)
>>> ws, hs = signal.freqs_zpk(filts.zeros, filts.poles, filts.gain,
...                           worN=fs*wz)
>>> plt.semilogx(wz*fs/(2*np.pi), 20*np.log10(np.abs(hz).clip(1e-15)),
...              label=r'$|H_z(e^{j \omega})|$')
>>> plt.semilogx(wz*fs/(2*np.pi), 20*np.log10(np.abs(hs).clip(1e-15)),
...              label=r'$|H(j \omega)|$')
>>> plt.legend()
>>> plt.xlabel('Frequency [Hz]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.grid()
```

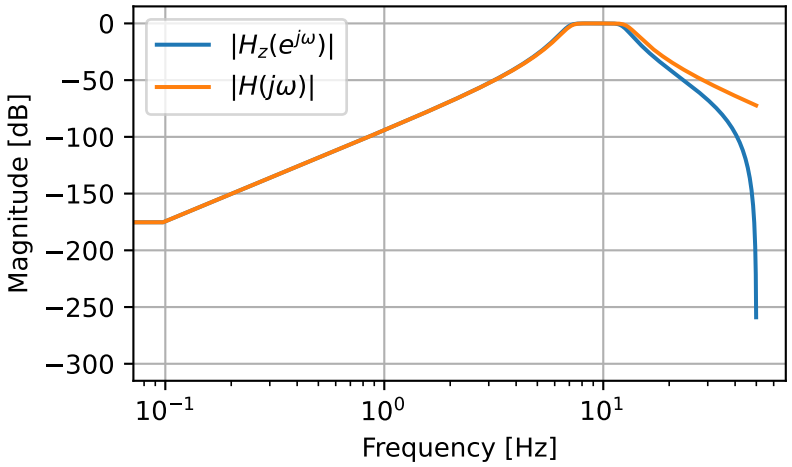
scipy.signal.findfreqs

scipy.signal.**findfreqs**(*num*, *den*, *N*, *kind='ba'*)

Find array of frequencies for computing the response of an analog filter.

Parameters

num, den [array_like, 1-D] The polynomial coefficients of the numerator and denominator of the transfer function of the filter or LTI system, where the coefficients are ordered from highest to lowest degree. Or, the roots of the transfer function numerator and denominator (i.e., zeroes and poles).
N [int] The length of the array to be computed.



kind [str {'ba', 'zp'}, optional] Specifies whether the numerator and denominator are specified by their polynomial coefficients ('ba'), or their roots ('zp').

Returns

w [(N,) ndarray] A 1-D array of frequencies, logarithmically spaced.

Examples

Find a set of nine frequencies that span the "interesting part" of the frequency response for the filter with the transfer function

H(s) = s / (s^2 + 8s + 25)

```
>>> from scipy import signal
>>> signal.findfreqs([1, 0], [1, 8, 25], N=9)
array([  1.00000000e-02,   3.16227766e-02,   1.00000000e-01,
         3.16227766e-01,   1.00000000e+00,   3.16227766e+00,
         1.00000000e+01,   3.16227766e+01,   1.00000000e+02])
```

scipy.signal.firls

`scipy.signal.`**`firls`**(*numtaps*, *bands*, *desired*, *weight=None*, *nyq=None*, *fs=None*)

FIR filter design using least-squares error minimization.

Calculate the filter coefficients for the linear-phase finite impulse response (FIR) filter which has the best approximation to the desired frequency response described by *bands* and *desired* in the least squares sense (i.e., the integral of the weighted mean-squared error within the specified bands is minimized).

Parameters

numtaps [int] The number of taps in the FIR filter. *numtaps* must be odd.

bands [array_like] A monotonic nondecreasing sequence containing the band edges in Hz. All elements must be non-negative and less than or equal to the Nyquist frequency given by *nyq*.

desired [array_like] A sequence the same size as *bands* containing the desired gain at the start and end point of each band.

weight [array_like, optional] A relative weighting to give to each band region when solving the least squares problem. *weight* has to be half the size of *bands*.

nyq [float, optional] *Deprecated. Use `fs` instead.* Nyquist frequency. Each frequency in *bands* must be between 0 and *nyq* (inclusive). Default is 1.

fs [float, optional] The sampling frequency of the signal. Each frequency in *bands* must be between 0 and `fs/2` (inclusive). Default is 2.

Returns

coeffs [ndarray] Coefficients of the optimal (in a least squares sense) FIR filter.

See also:

`firwin`

`firwin2`

`minimum_phase`

`remez`

Notes

This implementation follows the algorithm given in [1]. As noted there, least squares design has multiple advantages:

1. Optimal in a least-squares sense.
2. Simple, non-iterative method.
3. The general solution can obtained by solving a linear system of equations.
4. Allows the use of a frequency dependent weighting function.

This function constructs a Type I linear phase FIR filter, which contains an odd number of *coeffs* satisfying for $n < numtaps$:

$$coeffs(n) = coeffs(numtaps - 1 - n)$$

The odd number of coefficients and filter symmetry avoid boundary conditions that could otherwise occur at the Nyquist and 0 frequencies (e.g., for Type II, III, or IV variants).

New in version 0.18.

References

[1]

Examples

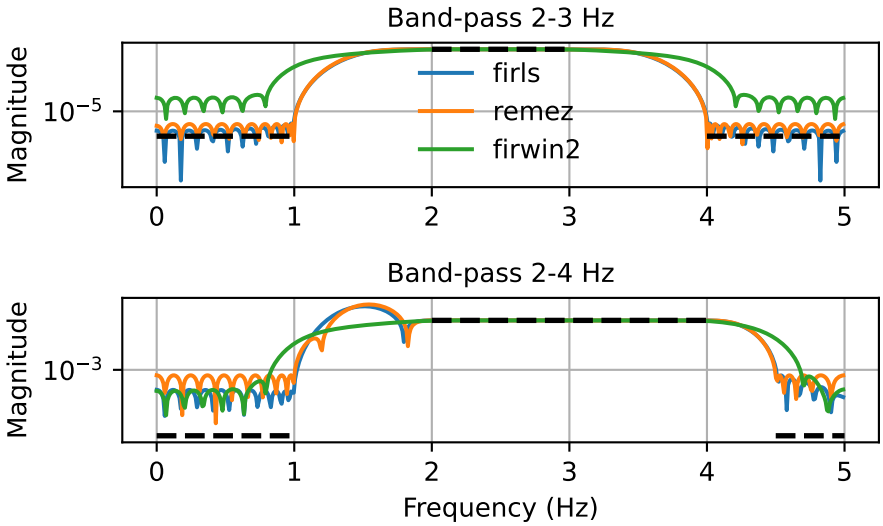
We want to construct a band-pass filter. Note that the behavior in the frequency ranges between our stop bands and pass bands is unspecified, and thus may overshoot depending on the parameters of our filter:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> fig, axs = plt.subplots(2)
>>> fs = 10.0  # Hz
>>> desired = (0, 0, 1, 1, 0, 0)
```

(continues on next page)

(continued from previous page)

```
>>> for bi, bands in enumerate(((0, 1, 2, 3, 4, 5), (0, 1, 2, 4, 4.5,␣
↪5))):
...     fir_firls = signal.firls(73, bands, desired, fs=fs)
...     fir_remez = signal.remez(73, bands, desired[::2], fs=fs)
...     fir_firwin2 = signal.firwin2(73, bands, desired, fs=fs)
...     hs = list()
...     ax = axs[bi]
...     for fir in (fir_firls, fir_remez, fir_firwin2):
...         freq, response = signal.freqz(fir)
...         hs.append(ax.semilogy(0.5*fs*freq/np.pi, np.abs(response))[0])
...     for band, gains in zip(zip(bands[::2], bands[1::2]),
...                            zip(desired[::2], desired[1::2])):
...         ax.semilogy(band, np.maximum(gains, 1e-7), 'k--', linewidth=2)
...     if bi == 0:
...         ax.legend(hs, ('firls', 'remez', 'firwin2'),
...                   loc='lower center', frameon=False)
...     else:
...         ax.set_xlabel('Frequency (Hz)')
...     ax.grid(True)
...     ax.set(title='Band-pass %d-%d Hz' % bands[2:4], ylabel='Magnitude
↪')
...
>>> fig.tight_layout()
>>> plt.show()
```



scipy.signal.firwin

scipy.signal.**firwin**(*numtaps*, *cutoff*, *width=None*, *window='hamming'*, *pass_zero=True*, *scale=True*, *nyq=None*, *fs=None*)

FIR filter design using the window method.

This function computes the coefficients of a finite impulse response filter. The filter will have linear phase; it will be Type I if *numtaps* is odd and Type II if *numtaps* is even.

Type II filters always have zero response at the Nyquist frequency, so a ValueError exception is raised if firwin is called with *numtaps* even and having a passband whose right end is at the Nyquist frequency.

Parameters

numtaps [int] Length of the filter (number of coefficients, i.e. the filter order + 1). *numtaps* must be odd if a passband includes the Nyquist frequency.

cutoff [float or 1-D array_like] Cutoff frequency of filter (expressed in the same units as *fs*) OR an array of cutoff frequencies (that is, band edges). In the latter case, the frequencies in *cutoff* should be positive and monotonically increasing between 0 and *fs/2*. The values 0 and *fs/2* must not be included in *cutoff*.

width [float or None, optional] If *width* is not None, then assume it is the approximate width of the transition region (expressed in the same units as *fs*) for use in Kaiser FIR filter design. In this case, the *window* argument is ignored.

window [string or tuple of string and parameter values, optional] Desired window to use. See *scipy.signal.get_window* for a list of windows and required parameters.

pass_zero [{True, False, 'bandpass', 'lowpass', 'highpass', 'bandstop'}, optional] If True, the gain at the frequency 0 (i.e., the "DC gain") is 1. If False, the DC gain is 0. Can also be a string argument for the desired filter type (equivalent to `btype` in IIR design functions).
New in version 1.3.0: Support for string arguments.

scale [bool, optional] Set to True to scale the coefficients so that the frequency response is exactly unity at a certain frequency. That frequency is either:
- 0 (DC) if the first passband starts at 0 (i.e. pass_zero is True)
- *fs/2* (the Nyquist frequency) if the first passband ends at *fs/2* (i.e the filter is a single band highpass filter); center of first passband otherwise

nyq [float, optional] *Deprecated. Use `fs` instead.* This is the Nyquist frequency. Each frequency in *cutoff* must be between 0 and *nyq*. Default is 1.

fs [float, optional] The sampling frequency of the signal. Each frequency in *cutoff* must be between 0 and `fs/2`. Default is 2.

Returns

h [(numtaps,) ndarray] Coefficients of length *numtaps* FIR filter.

Raises

ValueError

If any value in *cutoff* is less than or equal to 0 or greater than or equal to `fs/2`, if the values in *cutoff* are not strictly monotonically increasing, or if *numtaps* is even but a passband includes the Nyquist frequency.

Examples

Low-pass from 0 to f:

```
>>> from scipy import signal
>>> numtaps = 3
>>> f = 0.1
>>> signal.firwin(numtaps, f)
array([ 0.06799017,  0.86401967,  0.06799017])
```

Use a specific window function:

```
>>> signal.firwin(numtaps, f, window='nuttall')
array([  3.56607041e-04,   9.99286786e-01,   3.56607041e-04])
```

High-pass ('stop' from 0 to f):

```
>>> signal.firwin(numtaps, f, pass_zero=False)
array([-0.00859313,  0.98281375, -0.00859313])
```

Band-pass:

```
>>> f1, f2 = 0.1, 0.2
>>> signal.firwin(numtaps, [f1, f2], pass_zero=False)
array([ 0.06301614,  0.88770441,  0.06301614])
```

Band-stop:

```
>>> signal.firwin(numtaps, [f1, f2])
array([-0.00801395,  1.0160279 , -0.00801395])
```

Multi-band (passbands are [0, f1], [f2, f3] and [f4, 1]):

```
>>> f3, f4 = 0.3, 0.4
>>> signal.firwin(numtaps, [f1, f2, f3, f4])
array([-0.01376344,  1.02752689, -0.01376344])
```

Multi-band (passbands are [f1, f2] and [f3,f4]):

```
>>> signal.firwin(numtaps, [f1, f2, f3, f4], pass_zero=False)
array([ 0.04890915,  0.91284326,  0.04890915])
```

scipy.signal.firwin2

scipy.signal.**firwin2**(*numtaps*, *freq*, *gain*, *nfreqs=None*, *window='hamming'*, *nyq=None*, *antisymmetric=False*, *fs=None*)

FIR filter design using the window method.

From the given frequencies *freq* and corresponding gains *gain*, this function constructs an FIR filter with linear phase and (approximately) the given frequency response.

Parameters

numtaps [int] The number of taps in the FIR filter. *numtaps* must be less than *nfreqs*.

freq [array_like, 1-D] The frequency sampling points. Typically 0.0 to 1.0 with 1.0 being Nyquist. The Nyquist frequency is half *fs*. The values in *freq* must be nondecreasing. A value can be

repeated once to implement a discontinuity. The first value in *freq* must be 0, and the last value must be `fs/2`. Values 0 and `fs/2` must not be repeated.

gain [array_like] The filter gains at the frequency sampling points. Certain constraints to gain values, depending on the filter type, are applied, see Notes for details.

nfreqs [int, optional] The size of the interpolation mesh used to construct the filter. For most efficient behavior, this should be a power of 2 plus 1 (e.g, 129, 257, etc). The default is one more than the smallest power of 2 that is not less than *numtaps*. *nfreqs* must be greater than *numtaps*.

window [string or (string, float) or float, or None, optional] Window function to use. Default is "hamming". See *scipy.signal.get_window* for the complete list of possible values. If None, no window function is applied.

nyq [float, optional] *Deprecated. Use `fs` instead.* This is the Nyquist frequency. Each frequency in *freq* must be between 0 and *nyq*. Default is 1.

antisymmetric

[bool, optional] Whether resulting impulse response is symmetric/antisymmetric. See Notes for more details.

fs [float, optional] The sampling frequency of the signal. Each frequency in *cutoff* must be between 0 and `fs/2`. Default is 2.

Returns

taps [ndarray] The filter coefficients of the FIR filter, as a 1-D array of length *numtaps*.

firls

firwin

minimum_phase

remez

Notes

From the given set of frequencies and gains, the desired response is constructed in the frequency domain. The inverse FFT is applied to the desired response to create the associated convolution kernel, and the first *numtaps* coefficients of this kernel, scaled by *window*, are returned.

The FIR filter will have linear phase. The type of filter is determined by the value of 'numtaps` and *antisymmetric* flag. There are four possible combinations:

- odd *numtaps*, *antisymmetric* is False, type I filter is produced
- even *numtaps*, *antisymmetric* is False, type II filter is produced
- odd *numtaps*, *antisymmetric* is True, type III filter is produced
- even *numtaps*, *antisymmetric* is True, type IV filter is produced

Magnitude response of all but type I filters are subjects to following constraints:

- type II – zero at the Nyquist frequency
- type III – zero at zero and Nyquist frequencies
- type IV – zero at zero frequency

New in version 0.9.0.

References

[1], [2]

Examples

A lowpass FIR filter with a response that is 1 on [0.0, 0.5], and that decreases linearly on [0.5, 1.0] from 1 to 0:

```
>>> from scipy import signal
>>> taps = signal.firwin2(150, [0.0, 0.5, 1.0], [1.0, 1.0, 0.0])
>>> print(taps[72:78])
[-0.02286961 -0.06362756  0.57310236  0.57310236 -0.06362756 -0.02286961]
```

scipy.signal.freqs

scipy.signal.**freqs**(*b*, *a*, *worN=200*, *plot=None*)

Compute frequency response of analog filter.

Given the M-order numerator *b* and N-order denominator *a* of an analog filter, compute its frequency response:

```
         b[0]*(jw)**M + b[1]*(jw)**(M-1) + ... + b[M]
H(w) = ----------------------------------------------
         a[0]*(jw)**N + a[1]*(jw)**(N-1) + ... + a[N]
```

Parameters

b	[array_like] Numerator of a linear filter.
a	[array_like] Denominator of a linear filter.
worN	[{None, int, array_like}, optional] If None, then compute at 200 frequencies around the interesting parts of the response curve (determined by pole-zero locations). If a single integer, then compute at that many frequencies. Otherwise, compute the response at the angular frequencies (e.g., rad/s) given in *worN*.
plot	[callable, optional] A callable that takes two arguments. If given, the return parameters *w* and *h* are passed to plot. Useful for plotting the frequency response inside *freqs*.

Returns

w	[ndarray] The angular frequencies at which *h* was computed.
h	[ndarray] The frequency response.

See also:

freqz

Compute the frequency response of a digital filter.

Notes

Using Matplotlib's "plot" function as the callable for *plot* produces unexpected results, this plots the real part of the complex transfer function, not the magnitude. Try `lambda w, h: plot(w, abs(h))`.

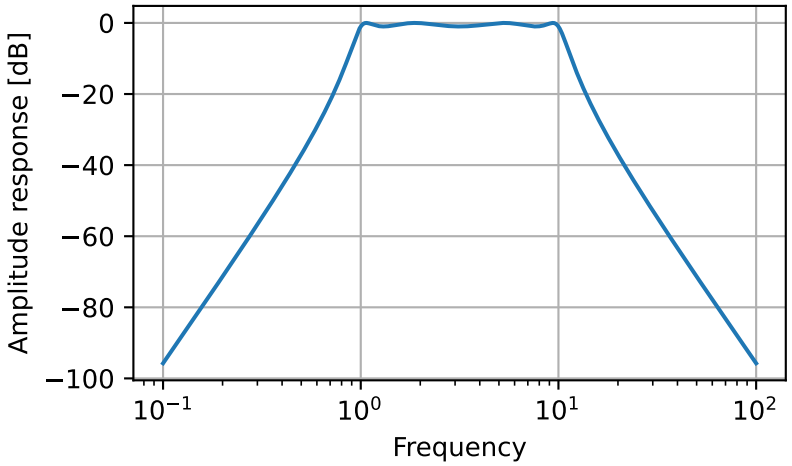
Examples

```
>>> from scipy.signal import freqs, iirfilter
```

```
>>> b, a = iirfilter(4, [1, 10], 1, 60, analog=True, ftype='cheby1')
```

```
>>> w, h = freqs(b, a, worN=np.logspace(-1, 2, 1000))
```

```
>>> import matplotlib.pyplot as plt
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude response [dB]')
>>> plt.grid()
>>> plt.show()
```



scipy.signal.freqs_zpk

`scipy.signal.`**`freqs_zpk`**(*z*, *p*, *k*, *worN=200*)

Compute frequency response of analog filter.

Given the zeros *z*, poles *p*, and gain *k* of a filter, compute its frequency response:

```
             (jw-z[0]) * (jw-z[1]) * ... * (jw-z[-1])
H(w) = k * ----------------------------------------
             (jw-p[0]) * (jw-p[1]) * ... * (jw-p[-1])
```

Parameters

z	[array_like] Zeroes of a linear filter
p	[array_like] Poles of a linear filter
k	[scalar] Gain of a linear filter
worN	[{None, int, array_like}, optional] If None, then compute at 200 frequencies around the interesting parts of the response curve (determined by pole-zero locations). If a single integer, then compute at that many frequencies. Otherwise, compute the response at the angular frequencies (e.g., rad/s) given in *worN*.

Returns

w	[ndarray] The angular frequencies at which *h* was computed.
h	[ndarray] The frequency response.

Compute the frequency response of a digital filter in TF form

freqz_zpk

Compute the frequency response of a digital filter in ZPK form

Notes

New in version 0.19.0.

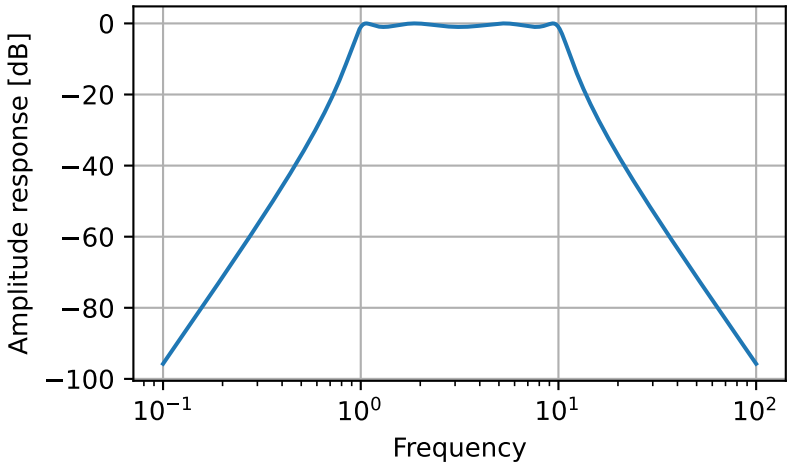
Examples

```
>>> from scipy.signal import freqs_zpk, iirfilter
```

```
>>> z, p, k = iirfilter(4, [1, 10], 1, 60, analog=True, ftype='cheby1',
...                     output='zpk')
```

```
>>> w, h = freqs_zpk(z, p, k, worN=np.logspace(-1, 2, 1000))
```

```
>>> import matplotlib.pyplot as plt
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude response [dB]')
>>> plt.grid()
>>> plt.show()
```



scipy.signal.freqz

`scipy.signal.`**`freqz`**(*b*, *a=1*, *worN=512*, *whole=False*, *plot=None*, *fs=6.283185307179586*, *include_nyquist=False*)

Compute the frequency response of a digital filter.

Given the M-order numerator *b* and N-order denominator *a* of a digital filter, compute its frequency response:

```
             jw                 -jw              -jwM
   jw     B(e  )     b[0] + b[1]e    + ... + b[M]e
H(e  ) = ------ = ----------------------------------
             jw                 -jw              -jwN
          A(e  )     a[0] + a[1]e    + ... + a[N]e
```

Parameters

b [array_like] Numerator of a linear filter. If *b* has dimension greater than 1, it is assumed that the coefficients are stored in the first dimension, and `b.shape[1:]`, `a.shape[1:]`, and the shape of the frequencies array must be compatible for broadcasting.

a [array_like] Denominator of a linear filter. If *b* has dimension greater than 1, it is assumed that the coefficients are stored in the first dimension, and `b.shape[1:]`, `a.shape[1:]`, and the shape of the frequencies array must be compatible for broadcasting.

worN [{None, int, array_like}, optional] If a single integer, then compute at that many frequencies (default is N=512). This is a convenient alternative to:

```
np.linspace(0, fs if whole else fs/2, N, endpoint=include_
↪nyquist)
```

Using a number that is fast for FFT computations can result in faster computations (see Notes).
If an array_like, compute the response at the frequencies given. These are in the same units as *fs*.

whole [bool, optional] Normally, frequencies are computed from 0 to the Nyquist frequency, fs/2 (upper-half of unit-circle). If *whole* is True, compute frequencies from 0 to fs. Ignored if worN is array_like.

plot [callable] A callable that takes two arguments. If given, the return parameters *w* and *h* are passed to plot. Useful for plotting the frequency response inside `freqz`.

fs [float, optional] The sampling frequency of the digital system. Defaults to 2*pi radians/sample (so w is from 0 to pi).
New in version 1.2.0.

include_nyquist
[bool, optional] If *whole* is False and *worN* is an integer, setting *include_nyquist* to True will include the last frequency (Nyquist frequency) and is otherwise ignored.
New in version 1.5.0.

Returns

w [ndarray] The frequencies at which *h* was computed, in the same units as *fs*. By default, *w* is normalized to the range [0, pi) (radians/sample).

h [ndarray] The frequency response, as complex numbers.

See also:

`freqz_zpk`

`sosfreqz`

Notes

Using Matplotlib's `matplotlib.pyplot.plot` function as the callable for *plot* produces unexpected results, as this plots the real part of the complex transfer function, not the magnitude. Try `lambda w, h: plot(w, np.abs(h))`.

A direct computation via (R)FFT is used to compute the frequency response when the following conditions are met:

1. An integer value is given for *worN*.
2. *worN* is fast to compute via FFT (i.e., `next_fast_len(worN)` equals *worN*).
3. The denominator coefficients are a single value (`a.shape[0] == 1`).
4. *worN* is at least as long as the numerator coefficients (`worN >= b.shape[0]`).
5. If `b.ndim > 1`, then `b.shape[-1] == 1`.

For long FIR filters, the FFT approach can have lower error and be much faster than the equivalent direct polynomial calculation.

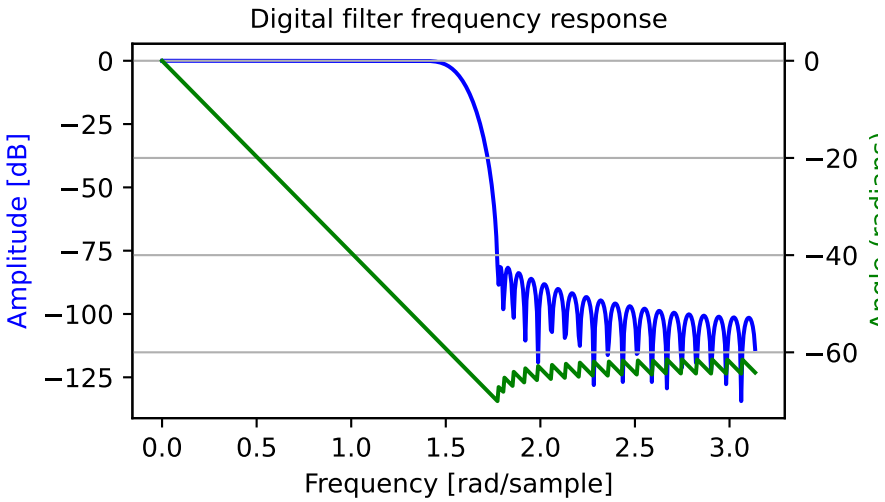
Examples

```
>>> from scipy import signal
>>> b = signal.firwin(80, 0.5, window=('kaiser', 8))
>>> w, h = signal.freqz(b)
```

```
>>> import matplotlib.pyplot as plt
>>> fig, ax1 = plt.subplots()
>>> ax1.set_title('Digital filter frequency response')
```

```
>>> ax1.plot(w, 20 * np.log10(abs(h)), 'b')
>>> ax1.set_ylabel('Amplitude [dB]', color='b')
>>> ax1.set_xlabel('Frequency [rad/sample]')
```

```
>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> ax2.plot(w, angles, 'g')
>>> ax2.set_ylabel('Angle (radians)', color='g')
>>> ax2.grid()
>>> ax2.axis('tight')
>>> plt.show()
```



Broadcasting Examples

Suppose we have two FIR filters whose coefficients are stored in the rows of an array with shape (2, 25). For this demonstration, we'll use random data:

```
>>> rng = np.random.default_rng()
>>> b = rng.random((2, 25))
```

To compute the frequency response for these two filters with one call to *freqz*, we must pass in `b.T`, because *freqz* expects the first axis to hold the coefficients. We must then extend the shape with a trivial dimension of length 1 to allow broadcasting with the array of frequencies. That is, we pass in `b.T[..., np.newaxis]`, which has shape (25, 2, 1):

```
>>> w, h = signal.freqz(b.T[..., np.newaxis], worN=1024)
>>> w.shape
(1024,)
>>> h.shape
(2, 1024)
```

Now, suppose we have two transfer functions, with the same numerator coefficients `b = [0.5, 0.5]`. The coefficients for the two denominators are stored in the first dimension of the 2-D array *a*:

```
a = [    1       1   ]
    [ -0.25, -0.5 ]
```

```
>>> b = np.array([0.5, 0.5])
>>> a = np.array([[1, 1], [-0.25, -0.5]])
```

Only *a* is more than 1-D. To make it compatible for broadcasting with the frequencies, we extend it with a trivial dimension in the call to *freqz*:

```
>>> w, h = signal.freqz(b, a[..., np.newaxis], worN=1024)
>>> w.shape
(1024,)
>>> h.shape
(2, 1024)
```

scipy.signal.freqz_zpk

scipy.signal.**freqz_zpk**(*z*, *p*, *k*, *worN=512*, *whole=False*, *fs=6.283185307179586*)

Compute the frequency response of a digital filter in ZPK form.

Given the Zeros, Poles and Gain of a digital filter, compute its frequency response:

$H(z) = k \prod_i (z - Z[i]) / \prod_j (z - P[j])$

where k is the *gain*, Z are the *zeros* and P are the *poles*.

Parameters

z	[array_like] Zeroes of a linear filter
p	[array_like] Poles of a linear filter
k	[scalar] Gain of a linear filter
worN	[{None, int, array_like}, optional] If a single integer, then compute at that many frequencies (default is N=512). If an array_like, compute the response at the frequencies given. These are in the same units as *fs*.
whole	[bool, optional] Normally, frequencies are computed from 0 to the Nyquist frequency, fs/2 (upper-half of unit-circle). If *whole* is True, compute frequencies from 0 to fs. Ignored if w is array_like.
fs	[float, optional] The sampling frequency of the digital system. Defaults to 2*pi radians/sample (so w is from 0 to pi). New in version 1.2.0.

Returns

w	[ndarray] The frequencies at which *h* was computed, in the same units as *fs*. By default, *w* is normalized to the range [0, pi) (radians/sample).
h	[ndarray] The frequency response, as complex numbers.

freqs

Compute the frequency response of an analog filter in TF form

freqs_zpk

Compute the frequency response of an analog filter in ZPK form

freqz

Compute the frequency response of a digital filter in TF form

Notes

New in version 0.19.0.

Examples

Design a 4th-order digital Butterworth filter with cut-off of 100 Hz in a system with sample rate of 1000 Hz, and plot the frequency response:

```
>>> from scipy import signal
>>> z, p, k = signal.butter(4, 100, output='zpk', fs=1000)
>>> w, h = signal.freqz_zpk(z, p, k, fs=1000)
```

```
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(1, 1, 1)
>>> ax1.set_title('Digital filter frequency response')
```

```
>>> ax1.plot(w, 20 * np.log10(abs(h)), 'b')
>>> ax1.set_ylabel('Amplitude [dB]', color='b')
>>> ax1.set_xlabel('Frequency [Hz]')
>>> ax1.grid()
```

```
>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> ax2.plot(w, angles, 'g')
>>> ax2.set_ylabel('Angle [radians]', color='g')
```

```
>>> plt.axis('tight')
>>> plt.show()
```

scipy.signal.sosfreqz

scipy.signal.**sosfreqz**(*sos*, *worN=512*, *whole=False*, *fs=6.283185307179586*)

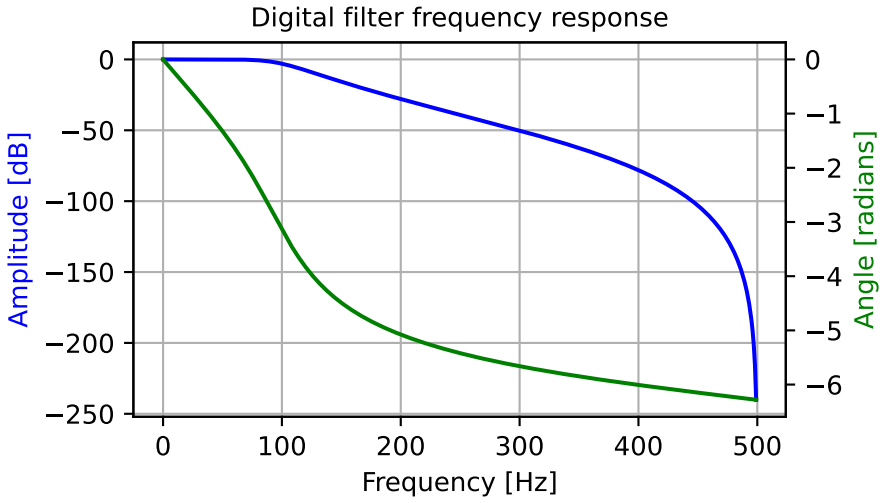
Compute the frequency response of a digital filter in SOS format.

Given *sos*, an array with shape (n, 6) of second order sections of a digital filter, compute the frequency response of the system function:

```
       B0(z)   B1(z)         B{n-1}(z)
H(z) = ----- * ----- * ... * ---------
       A0(z)   A1(z)         A{n-1}(z)
```

for z = exp(omega*1j), where B{k}(z) and A{k}(z) are numerator and denominator of the transfer function of the k-th second order section.

Parameters



sos [array_like] Array of second-order filter coefficients, must have shape `(n_sections, 6)`. Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.

worN [{None, int, array_like}, optional] If a single integer, then compute at that many frequencies (default is N=512). Using a number that is fast for FFT computations can result in faster computations (see Notes of *freqz*).
If an array_like, compute the response at the frequencies given (must be 1-D). These are in the same units as *fs*.

whole [bool, optional] Normally, frequencies are computed from 0 to the Nyquist frequency, fs/2 (upper-half of unit-circle). If *whole* is True, compute frequencies from 0 to fs.

fs [float, optional] The sampling frequency of the digital system. Defaults to 2*pi radians/sample (so w is from 0 to pi).
New in version 1.2.0.

Returns

w [ndarray] The frequencies at which *h* was computed, in the same units as *fs*. By default, *w* is normalized to the range [0, pi) (radians/sample).

h [ndarray] The frequency response, as complex numbers.

See also:

freqz, **sosfilt**

Notes

New in version 0.19.0.

Examples

Design a 15th-order bandpass filter in SOS format.

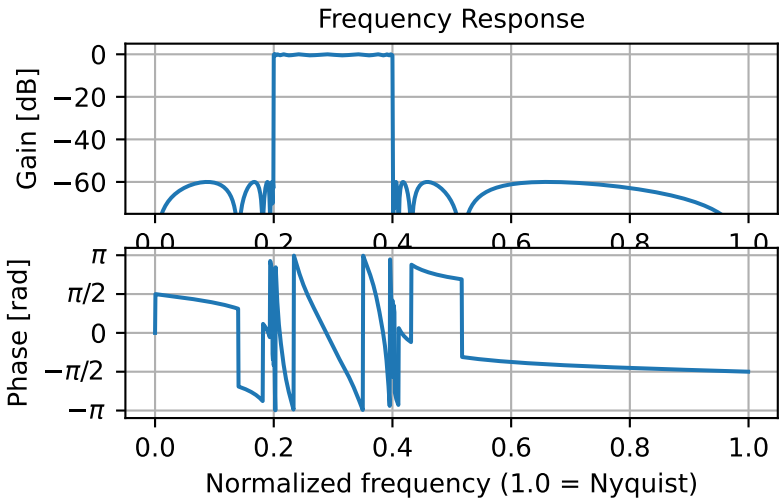
```
>>> from scipy import signal
>>> sos = signal.ellip(15, 0.5, 60, (0.2, 0.4), btype='bandpass',
...                    output='sos')
```

Compute the frequency response at 1500 points from DC to Nyquist.

```
>>> w, h = signal.sosfreqz(sos, worN=1500)
```

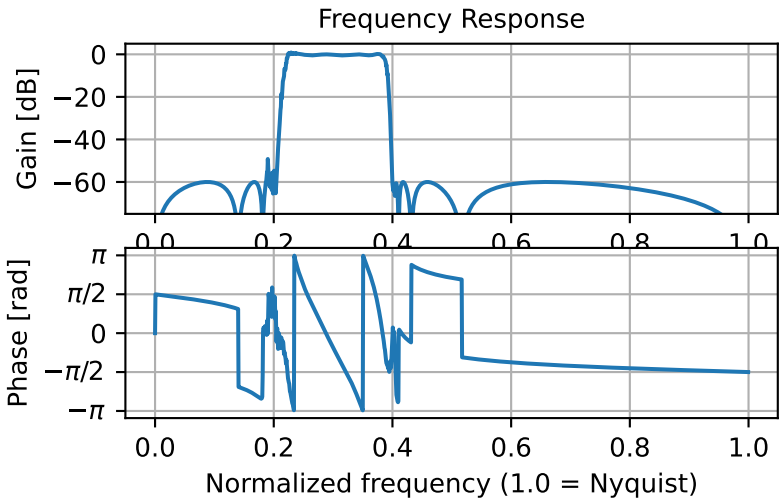
Plot the response.

```
>>> import matplotlib.pyplot as plt
>>> plt.subplot(2, 1, 1)
>>> db = 20*np.log10(np.maximum(np.abs(h), 1e-5))
>>> plt.plot(w/np.pi, db)
>>> plt.ylim(-75, 5)
>>> plt.grid(True)
>>> plt.yticks([0, -20, -40, -60])
>>> plt.ylabel('Gain [dB]')
>>> plt.title('Frequency Response')
>>> plt.subplot(2, 1, 2)
>>> plt.plot(w/np.pi, np.angle(h))
>>> plt.grid(True)
>>> plt.yticks([-np.pi, -0.5*np.pi, 0, 0.5*np.pi, np.pi],
...            [r'$-\pi$', r'$-\pi/2$', '0', r'$\pi/2$', r'$\pi$'])
>>> plt.ylabel('Phase [rad]')
>>> plt.xlabel('Normalized frequency (1.0 = Nyquist)')
>>> plt.show()
```



If the same filter is implemented as a single transfer function, numerical error corrupts the frequency response:

```
>>> b, a = signal.ellip(15, 0.5, 60, (0.2, 0.4), btype='bandpass',
...                     output='ba')
>>> w, h = signal.freqz(b, a, worN=1500)
>>> plt.subplot(2, 1, 1)
>>> db = 20*np.log10(np.maximum(np.abs(h), 1e-5))
>>> plt.plot(w/np.pi, db)
>>> plt.ylim(-75, 5)
>>> plt.grid(True)
>>> plt.yticks([0, -20, -40, -60])
>>> plt.ylabel('Gain [dB]')
>>> plt.title('Frequency Response')
>>> plt.subplot(2, 1, 2)
>>> plt.plot(w/np.pi, np.angle(h))
>>> plt.grid(True)
>>> plt.yticks([-np.pi, -0.5*np.pi, 0, 0.5*np.pi, np.pi],
...            [r'$-\pi$', r'$-\pi/2$', '0', r'$\pi/2$', r'$\pi$'])
>>> plt.ylabel('Phase [rad]')
>>> plt.xlabel('Normalized frequency (1.0 = Nyquist)')
>>> plt.show()
```



scipy.signal.gammatone

`scipy.signal.`**`gammatone`**(*freq*, *ftype*, *order=None*, *numtaps=None*, *fs=None*)

Gammatone filter design.

This function computes the coefficients of an FIR or IIR gammatone digital filter [1].

Parameters

freq [float] Center frequency of the filter (expressed in the same units as *fs*).

ftype [{'fir', 'iir'}] The type of filter the function generates. If 'fir', the function will generate an Nth order FIR gammatone filter. If 'iir', the function will generate an 8th order digital IIR filter, modeled as as 4th order gammatone filter.

order [int, optional] The order of the filter. Only used when `ftype='fir'`. Default is 4 to model the human auditory system. Must be between 0 and 24.

numtaps [int, optional] Length of the filter. Only used when `ftype='fir'`. Default is `fs*0.015` if *fs* is greater than 1000, 15 if *fs* is less than or equal to 1000.

fs [float, optional] The sampling frequency of the signal. *freq* must be between 0 and `fs/2`. Default is 2.

Returns

b, a [ndarray, ndarray] Numerator (`b`) and denominator (`a`) polynomials of the filter.

Raises

ValueError

If *freq* is less than or equal to 0 or greater than or equal to `fs/2`, if *ftype* is not 'fir' or 'iir', if *order* is less than or equal to 0 or greater than 24 when `ftype='fir'`

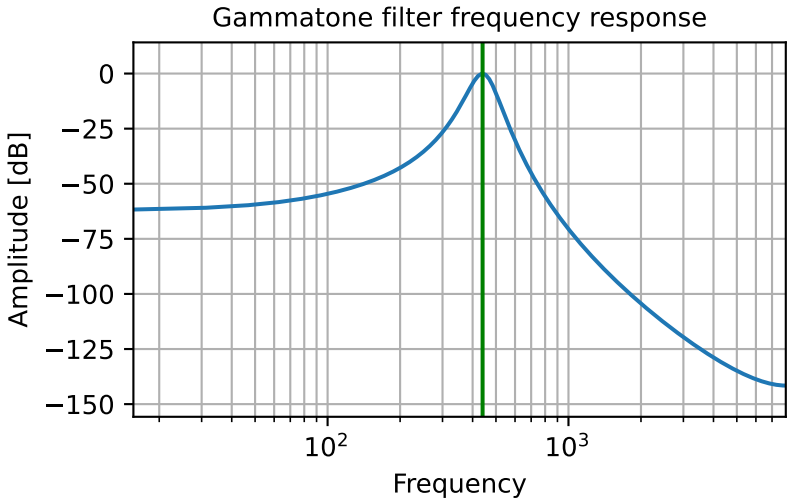
   [1.0])
```

IIR Gammatone filter centered at 440 Hz

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> b, a = signal.gammatone(440, 'iir', fs=16000)
>>> w, h = signal.freqz(b, a)
>>> plt.plot(w / ((2 * np.pi) / 16000), 20 * np.log10(abs(h)))
>>> plt.xscale('log')
>>> plt.title('Gammatone filter frequency response')
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(440, color='green') # cutoff frequency
>>> plt.show()
```



scipy.signal.group_delay

scipy.signal.**group_delay**(*system*, *w=512*, *whole=False*, *fs=6.283185307179586*)

Compute the group delay of a digital filter.

The group delay measures by how many samples amplitude envelopes of various spectral components of a signal are delayed by a filter. It is formally defined as the derivative of continuous (unwrapped) phase:

```
            d        jw
D(w) = - -- arg H(e)
           dw
```

Parameters

system [tuple of array_like (b, a)] Numerator and denominator coefficients of a filter transfer function.

w [{None, int, array_like}, optional] If a single integer, then compute at that many frequencies (default is N=512).
If an array_like, compute the delay at the frequencies given. These are in the same units as *fs*.

whole [bool, optional] Normally, frequencies are computed from 0 to the Nyquist frequency, fs/2 (upper-half of unit-circle). If *whole* is True, compute frequencies from 0 to fs. Ignored if w is array_like.

fs [float, optional] The sampling frequency of the digital system. Defaults to 2*pi radians/sample (so w is from 0 to pi).
New in version 1.2.0.

Returns

w [ndarray] The frequencies at which group delay was computed, in the same units as *fs*. By default, *w* is normalized to the range [0, pi) (radians/sample).

gd [ndarray] The group delay.

See also:

freqz

Frequency response of a digital filter

Notes

The similar function in MATLAB is called *grpdelay*.

If the transfer function $H(z)$ has zeros or poles on the unit circle, the group delay at corresponding frequencies is undefined. When such a case arises the warning is raised and the group delay is set to 0 at those frequencies.

For the details of numerical computation of the group delay refer to [1].

New in version 0.16.0.

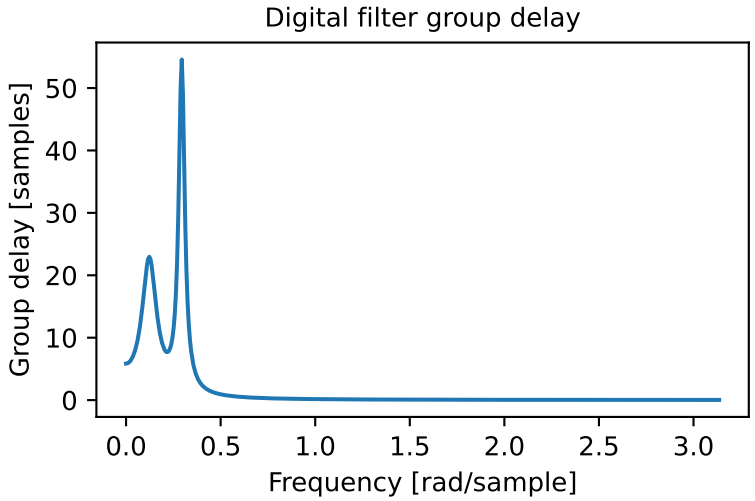
References

[1]

Examples

```
>>> from scipy import signal
>>> b, a = signal.iirdesign(0.1, 0.3, 5, 50, ftype='cheby1')
>>> w, gd = signal.group_delay((b, a))
```

```
>>> import matplotlib.pyplot as plt
>>> plt.title('Digital filter group delay')
>>> plt.plot(w, gd)
>>> plt.ylabel('Group delay [samples]')
>>> plt.xlabel('Frequency [rad/sample]')
>>> plt.show()
```



scipy.signal.iirdesign

scipy.signal.**iirdesign**(*wp*, *ws*, *gpass*, *gstop*, *analog=False*, *ftype='ellip'*, *output='ba'*, *fs=None*)

Complete IIR digital and analog filter design.

Given passband and stopband frequencies and gains, construct an analog or digital IIR filter of minimum order for a given basic type. Return the output in numerator, denominator ('ba'), pole-zero ('zpk') or second order sections ('sos') form.

Parameters

wp, ws [float or array like, shape (2,)] Passband and stopband edge frequencies. Possible values are scalars (for lowpass and highpass filters) or ranges (for bandpass and bandstop filters). For digital filters, these are in the same units as *fs*. By default, *fs* is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. For example:
- Lowpass: wp = 0.2, ws = 0.3
- Highpass: wp = 0.3, ws = 0.2
- Bandpass: wp = [0.2, 0.5], ws = [0.1, 0.6]
- Bandstop: wp = [0.1, 0.6], ws = [0.2, 0.5]

For analog filters, *wp* and *ws* are angular frequencies (e.g., rad/s). Note, that for bandpass and bandstop filters passband must lie strictly inside stopband or vice versa.

gpass [float] The maximum loss in the passband (dB).

gstop [float] The minimum attenuation in the stopband (dB).

analog [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

ftype [str, optional] The type of IIR filter to design:
- Butterworth : 'butter'
- Chebyshev I : 'cheby1'
- Chebyshev II : 'cheby2'
- Cauer/elliptic: 'ellip'
- Bessel/Thomson: 'bessel'

output [{'ba', 'zpk', 'sos'}, optional] Filter form of the output:
- second-order sections (recommended): 'sos'
- numerator/denominator (default) : 'ba'
- pole-zero : 'zpk'

In general the second-order sections ('sos') form is recommended because inferring the coefficients for the numerator/denominator form ('ba') suffers from numerical instabilities. For reasons of backward compatibility the default form is the numerator/denominator form ('ba'), where the 'b' and the 'a' in 'ba' refer to the commonly used names of the coefficients used.
Note: Using the second-order sections form ('sos') is sometimes associated with additional computational costs: for data-intense use cases it is therefore recommended to also investigate the numerator/denominator form ('ba').

fs [float, optional] The sampling frequency of the digital system.
New in version 1.2.0.

Returns

b, a [ndarray, ndarray] Numerator (*b*) and denominator (*a*) polynomials of the IIR filter. Only returned if `output='ba'`.

z, p, k [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

sos [ndarray] Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

Notes

The `'sos'` output parameter was added in 0.16.0.

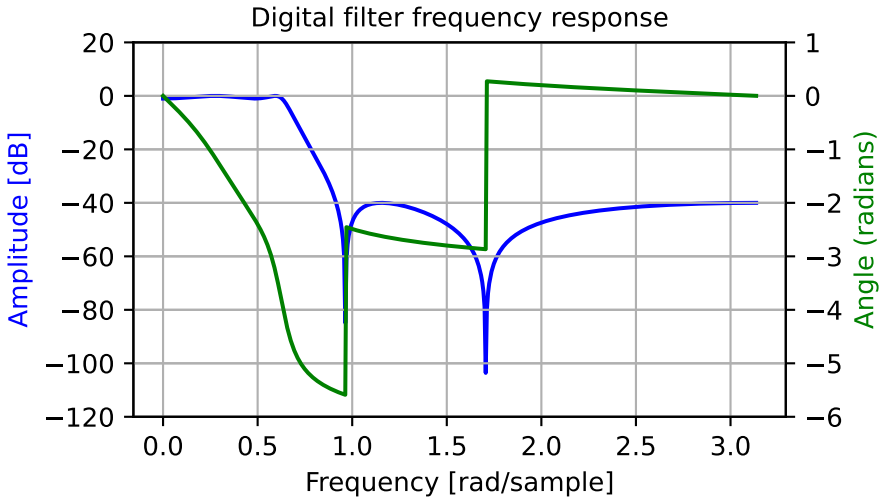
Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> import matplotlib.ticker
```

```
>>> wp = 0.2
>>> ws = 0.3
>>> gpass = 1
>>> gstop = 40
```

```
>>> system = signal.iirdesign(wp, ws, gpass, gstop)
>>> w, h = signal.freqz(*system)
```

```
>>> fig, ax1 = plt.subplots()
>>> ax1.set_title('Digital filter frequency response')
>>> ax1.plot(w, 20 * np.log10(abs(h)), 'b')
>>> ax1.set_ylabel('Amplitude [dB]', color='b')
>>> ax1.set_xlabel('Frequency [rad/sample]')
>>> ax1.grid()
>>> ax1.set_ylim([-120, 20])
>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> ax2.plot(w, angles, 'g')
>>> ax2.set_ylabel('Angle (radians)', color='g')
>>> ax2.grid()
>>> ax2.axis('tight')
>>> ax2.set_ylim([-6, 1])
>>> nticks = 8
>>> ax1.yaxis.set_major_locator(matplotlib.ticker.LinearLocator(nticks))
>>> ax2.yaxis.set_major_locator(matplotlib.ticker.LinearLocator(nticks))
```



scipy.signal.iirfilter

`scipy.signal.`**`iirfilter`**(*N*, *Wn*, *rp=None*, *rs=None*, *btype='band'*, *analog=False*, *ftype='butter'*, *output='ba'*, *fs=None*)

IIR digital and analog filter design given order and critical points.

Design an Nth-order digital or analog filter and return the filter coefficients.

Parameters

N [int] The order of the filter.

Wn [array_like] A scalar or length-2 sequence giving the critical frequencies.
For digital filters, *Wn* are in the same units as *fs*. By default, *fs* is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (*Wn* is thus in half-cycles / sample.)
For analog filters, *Wn* is an angular frequency (e.g., rad/s).

rp [float, optional] For Chebyshev and elliptic filters, provides the maximum ripple in the passband. (dB)

rs [float, optional] For Chebyshev and elliptic filters, provides the minimum attenuation in the stop band. (dB)

btype [{'bandpass', 'lowpass', 'highpass', 'bandstop'}, optional] The type of filter. Default is 'bandpass'.

analog [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

ftype [str, optional] The type of IIR filter to design:
- Butterworth : 'butter'
- Chebyshev I : 'cheby1'
- Chebyshev II : 'cheby2'
- Cauer/elliptic: 'ellip'
- Bessel/Thomson: 'bessel'

output [{'ba', 'zpk', 'sos'}, optional] Filter form of the output:
- second-order sections (recommended): 'sos'
- numerator/denominator (default) : 'ba'
- pole-zero : 'zpk'

In general the second-order sections ('sos') form is recommended because inferring the coefficients for the numerator/denominator form ('ba') suffers from numerical instabilities. For

reasons of backward compatibility the default form is the numerator/denominator form ('ba'), where the 'b' and the 'a' in 'ba' refer to the commonly used names of the coefficients used. Note: Using the second-order sections form ('sos') is sometimes associated with additional computational costs: for data-intense use cases it is therefore recommended to also investigate the numerator/denominator form ('ba').

fs [float, optional] The sampling frequency of the digital system. New in version 1.2.0.

Returns

b, a [ndarray, ndarray] Numerator (*b*) and denominator (*a*) polynomials of the IIR filter. Only returned if `output='ba'`.

z, p, k [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

sos [ndarray] Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

iirdesign

General filter design using passband and stopband spec

Notes

The `'sos'` output parameter was added in 0.16.0.

Examples

Generate a 17th-order Chebyshev II analog bandpass filter from 50 Hz to 200 Hz and plot the frequency response:

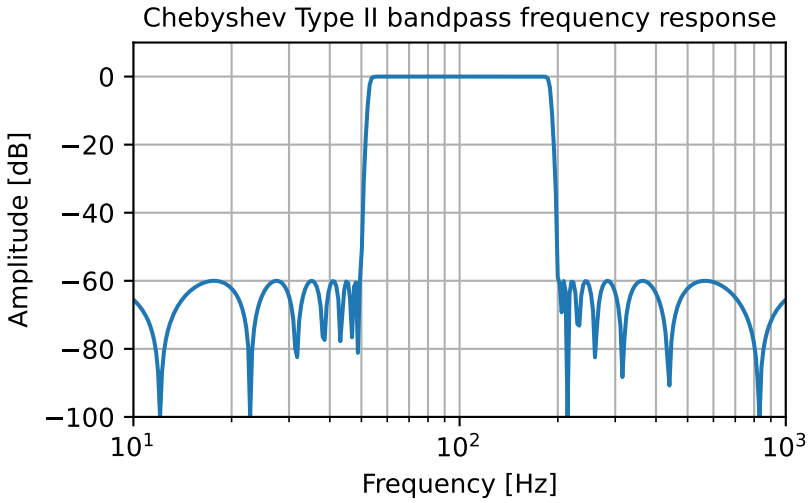
```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> b, a = signal.iirfilter(17, [2*np.pi*50, 2*np.pi*200], rs=60,
...                         btype='band', analog=True, ftype='cheby2')
>>> w, h = signal.freqs(b, a, 1000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.semilogx(w / (2*np.pi), 20 * np.log10(np.maximum(abs(h), 1e-5)))
>>> ax.set_title('Chebyshev Type II bandpass frequency response')
>>> ax.set_xlabel('Frequency [Hz]')
>>> ax.set_ylabel('Amplitude [dB]')
>>> ax.axis((10, 1000, -100, 10))
```

(continues on next page)

(continued from previous page)

```
>>> ax.grid(which='both', axis='both')
>>> plt.show()
```



Create a digital filter with the same properties, in a system with sampling rate of 2000 Hz, and plot the frequency response. (Second-order sections implementation is required to ensure stability of a filter of this order):

```
>>> sos = signal.iirfilter(17, [50, 200], rs=60, btype='band',
...                        analog=False, ftype='cheby2', fs=2000,
...                        output='sos')
>>> w, h = signal.sosfreqz(sos, 2000, fs=2000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.semilogx(w, 20 * np.log10(np.maximum(abs(h), 1e-5)))
>>> ax.set_title('Chebyshev Type II bandpass frequency response')
>>> ax.set_xlabel('Frequency [Hz]')
>>> ax.set_ylabel('Amplitude [dB]')
>>> ax.axis((10, 1000, -100, 10))
>>> ax.grid(which='both', axis='both')
>>> plt.show()
```

scipy.signal.kaiser_atten

scipy.signal.**kaiser_atten**(*numtaps*, *width*)

Compute the attenuation of a Kaiser FIR filter.

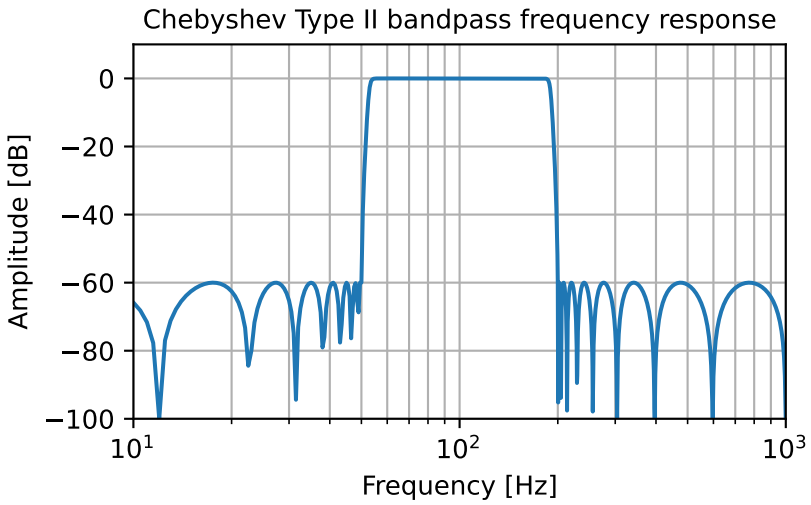
Given the number of taps *N* and the transition width *width*, compute the attenuation *a* in dB, given by Kaiser's formula:

a = 2.285 * (N - 1) * pi * width + 7.95

Parameters

numtaps [int] The number of taps in the FIR filter.

width [float] The desired width of the transition region between passband and stopband (or, in general, at any discontinuity) for the filter, expressed as a fraction of the Nyquist frequency.



Returns

a [float] The attenuation of the ripple, in dB.

See also:

kaiserord, **kaiser_beta**

Examples

Suppose we want to design a FIR filter using the Kaiser window method that will have 211 taps and a transition width of 9 Hz for a signal that is sampled at 480 Hz. Expressed as a fraction of the Nyquist frequency, the width is 9/(0.5*480) = 0.0375. The approximate attenuation (in dB) is computed as follows:

```
>>> from scipy.signal import kaiser_atten
>>> kaiser_atten(211, 0.0375)
64.48099630593983
```

scipy.signal.kaiser_beta

scipy.signal.**kaiser_beta**(*a*)

Compute the Kaiser parameter *beta*, given the attenuation *a*.

Parameters

a [float] The desired attenuation in the stopband and maximum ripple in the passband, in dB. This should be a *positive* number.

Returns

beta [float] The *beta* parameter to be used in the formula for a Kaiser window.

References

Oppenheim, Schafer, "Discrete-Time Signal Processing", p.475-476.

Examples

Suppose we want to design a lowpass filter, with 65 dB attenuation in the stop band. The Kaiser window parameter to be used in the window method is computed by *kaiser_beta(65)*:

```
>>> from scipy.signal import kaiser_beta
>>> kaiser_beta(65)
6.20426
```

scipy.signal.kaiserord

scipy.signal.**kaiserord**(*ripple*, *width*)

Determine the filter window parameters for the Kaiser window method.

The parameters returned by this function are generally used to create a finite impulse response filter using the window method, with either *firwin* or *firwin2*.

Parameters

ripple [float] Upper bound for the deviation (in dB) of the magnitude of the filter's frequency response from that of the desired filter (not including frequencies in any transition intervals). That is, if w is the frequency expressed as a fraction of the Nyquist frequency, A(w) is the actual frequency response of the filter and D(w) is the desired frequency response, the design requirement is that:

```
abs(A(w) - D(w)) < 10**(-ripple/20)
```

for 0 <= w <= 1 and w not in a transition interval.

width [float] Width of transition region, normalized so that 1 corresponds to pi radians / sample. That is, the frequency is expressed as a fraction of the Nyquist frequency.

Returns

numtaps [int] The length of the Kaiser window.

beta [float] The beta parameter for the Kaiser window.

See also:

kaiser_beta, **kaiser_atten**

Notes

There are several ways to obtain the Kaiser window:

- `signal.windows.kaiser(numtaps, beta, sym=True)`
- `signal.get_window(beta, numtaps)`
- `signal.get_window(('kaiser', beta), numtaps)`

The empirical equations discovered by Kaiser are used.

References

Oppenheim, Schafer, "Discrete-Time Signal Processing", pp.475-476.

Examples

We will use the Kaiser window method to design a lowpass FIR filter for a signal that is sampled at 1000 Hz.

We want at least 65 dB rejection in the stop band, and in the pass band the gain should vary no more than 0.5%.

We want a cutoff frequency of 175 Hz, with a transition between the pass band and the stop band of 24 Hz. That is, in the band [0, 163], the gain varies no more than 0.5%, and in the band [187, 500], the signal is attenuated by at least 65 dB.

```
>>> from scipy.signal import kaiserord, firwin, freqz
>>> import matplotlib.pyplot as plt
>>> fs = 1000.0
>>> cutoff = 175
>>> width = 24
```

The Kaiser method accepts just a single parameter to control the pass band ripple and the stop band rejection, so we use the more restrictive of the two. In this case, the pass band ripple is 0.005, or 46.02 dB, so we will use 65 dB as the design parameter.

Use *kaiserord* to determine the length of the filter and the parameter for the Kaiser window.

```
>>> numtaps, beta = kaiserord(65, width/(0.5*fs))
>>> numtaps
167
>>> beta
6.20426
```

Use *firwin* to create the FIR filter.

```
>>> taps = firwin(numtaps, cutoff, window=('kaiser', beta),
...               scale=False, nyq=0.5*fs)
```

Compute the frequency response of the filter. `w` is the array of frequencies, and `h` is the corresponding complex array of frequency responses.

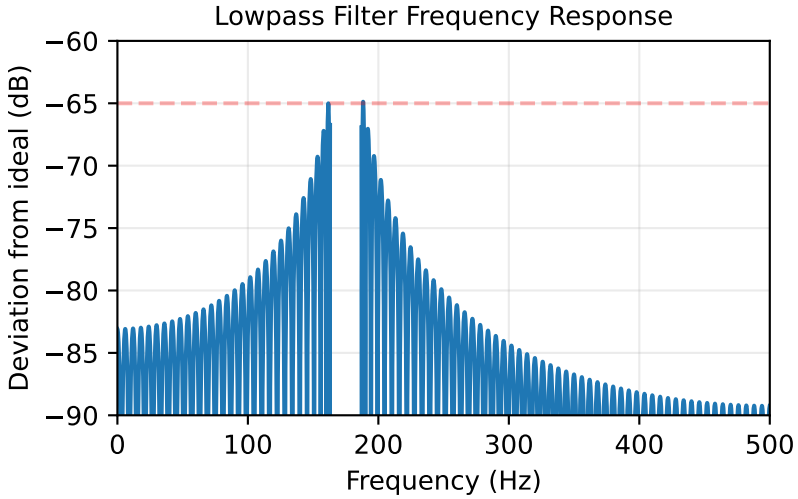
```
>>> w, h = freqz(taps, worN=8000)
>>> w *= 0.5*fs/np.pi  # Convert w to Hz.
```

Compute the deviation of the magnitude of the filter's response from that of the ideal lowpass filter. Values in the transition region are set to `nan`, so they won't appear in the plot.

```
>>> ideal = w < cutoff  # The "ideal" frequency response.
>>> deviation = np.abs(np.abs(h) - ideal)
>>> deviation[(w > cutoff - 0.5*width) & (w < cutoff + 0.5*width)] = np.
↪nan
```

Plot the deviation. A close look at the left end of the stop band shows that the requirement for 65 dB attenuation is violated in the first lobe by about 0.125 dB. This is not unusual for the Kaiser window method.

```
>>> plt.plot(w, 20*np.log10(np.abs(deviation)))
>>> plt.xlim(0, 0.5*fs)
>>> plt.ylim(-90, -60)
>>> plt.grid(alpha=0.25)
>>> plt.axhline(-65, color='r', ls='--', alpha=0.3)
>>> plt.xlabel('Frequency (Hz)')
>>> plt.ylabel('Deviation from ideal (dB)')
>>> plt.title('Lowpass Filter Frequency Response')
>>> plt.show()
```



scipy.signal.minimum_phase

scipy.signal.**minimum_phase**(*h*, *method='homomorphic'*, *n_fft=None*)

Convert a linear-phase FIR filter to minimum phase

Parameters

h [array] Linear-phase FIR filter coefficients.

method [{'hilbert', 'homomorphic'}] The method to use:

'homomorphic' (default)
This method [4] [5] works best with filters with an odd number of taps, and the resulting minimum phase filter will have a magnitude response that approximates the square root of the the original filter's magnitude response.

'hilbert' This method [1] is designed to be used with equiripple filters (e.g., from *remez*) with unity or zero gain regions.

n_fft [int] The number of points to use for the FFT. Should be at least a few times larger than the signal length (see Notes).

Returns

h_minimum
[array] The minimum-phase version of the filter, with length `(length(h) + 1) // 2`.

See also:

firwin

firwin2

remez

Notes

Both the Hilbert [1] or homomorphic [4] [5] methods require selection of an FFT length to estimate the complex cepstrum of the filter.

In the case of the Hilbert method, the deviation from the ideal spectrum `epsilon` is related to the number of stopband zeros `n_stop` and FFT length `n_fft` as:

```
epsilon = 2. * n_stop / n_fft
```

For example, with 100 stopband zeros and a FFT length of 2048, `epsilon = 0.0976`. If we conservatively assume that the number of stopband zeros is one less than the filter length, we can take the FFT length to be the next power of 2 that satisfies `epsilon=0.01` as:

```
n_fft = 2 ** int(np.ceil(np.log2(2 * (len(h) - 1) / 0.01)))
```

This gives reasonable results for both the Hilbert and homomorphic methods, and gives the value used when `n_fft=None`.

Alternative implementations exist for creating minimum-phase filters, including zero inversion [2] and spectral factorization [3] [4]. For more information, see:

http://dspguru.com/dsp/howtos/how-to-design-minimum-phase-fir-filters

References

[1], [2], [3], [4], [5]

Examples

Create an optimal linear-phase filter, then convert it to minimum phase:

```
>>> from scipy.signal import remez, minimum_phase, freqz, group_delay
>>> import matplotlib.pyplot as plt
>>> freq = [0, 0.2, 0.3, 1.0]
>>> desired = [1, 0]
>>> h_linear = remez(151, freq, desired, Hz=2.)
```

Convert it to minimum phase:

```
>>> h_min_hom = minimum_phase(h_linear, method='homomorphic')
>>> h_min_hil = minimum_phase(h_linear, method='hilbert')
```

Compare the three filters:

```
>>> fig, axs = plt.subplots(4, figsize=(4, 8))
>>> for h, style, color in zip((h_linear, h_min_hom, h_min_hil),
...                            ('-', '-', '--'), ('k', 'r', 'c')):
...     w, H = freqz(h)
...     w, gd = group_delay((h, 1))
```

(continues on next page)

(continued from previous page)

```
...     w /= np.pi
...     axs[0].plot(h, color=color, linestyle=style)
...     axs[1].plot(w, np.abs(H), color=color, linestyle=style)
...     axs[2].plot(w, 20 * np.log10(np.abs(H)), color=color,␣
↪linestyle=style)
...     axs[3].plot(w, gd, color=color, linestyle=style)
>>> for ax in axs:
...     ax.grid(True, color='0.5')
...     ax.fill_between(freq[1:3], *ax.get_ylim(), color='#ffeeaa',␣
↪zorder=1)
>>> axs[0].set(xlim=[0, len(h_linear) - 1], ylabel='Amplitude', xlabel=
↪'Samples')
>>> axs[1].legend(['Linear', 'Min-Hom', 'Min-Hil'], title='Phase')
>>> for ax, ylim in zip(axs[1:], ([0, 1.1], [-150, 10], [-60, 60])):
...     ax.set(xlim=[0, 1], ylim=ylim, xlabel='Frequency')
>>> axs[1].set(ylabel='Magnitude')
>>> axs[2].set(ylabel='Magnitude (dB)')
>>> axs[3].set(ylabel='Group delay')
>>> plt.tight_layout()
```

scipy.signal.savgol_coeffs

scipy.signal.**savgol_coeffs**(*window_length*, *polyorder*, *deriv=0*, *delta=1.0*, *pos=None*, *use='conv'*)

Compute the coefficients for a 1-D Savitzky-Golay FIR filter.

Parameters

window_length
: [int] The length of the filter window (i.e., the number of coefficients). *window_length* must be an odd positive integer.

polyorder
: [int] The order of the polynomial used to fit the samples. *polyorder* must be less than *window_length*.

deriv
: [int, optional] The order of the derivative to compute. This must be a nonnegative integer. The default is 0, which means to filter the data without differentiating.

delta
: [float, optional] The spacing of the samples to which the filter will be applied. This is only used if deriv > 0.

pos
: [int or None, optional] If pos is not None, it specifies evaluation position within the window. The default is the middle of the window.

use
: [str, optional] Either 'conv' or 'dot'. This argument chooses the order of the coefficients. The default is 'conv', which means that the coefficients are ordered to be used in a convolution. With use='dot', the order is reversed, so the filter is applied by dotting the coefficients with the data set.

Returns

coeffs
: [1-D ndarray] The filter coefficients.

A. Savitzky, M. J. E. Golay, Smoothing and Differentiation of Data by Simplified Least Squares Procedures. Analytical Chemistry, 1964, 36 (8), pp 1627-1639.

Examples

```
>>> from scipy.signal import savgol_coeffs
>>> savgol_coeffs(5, 2)
array([-0.08571429,  0.34285714,  0.48571429,  0.34285714, -0.08571429])
>>> savgol_coeffs(5, 2, deriv=1)
array([ 2.00000000e-01,  1.00000000e-01,  2.07548111e-16, -1.00000000e-01,
       -2.00000000e-01])
```

Note that use='dot' simply reverses the coefficients.

```
>>> savgol_coeffs(5, 2, pos=3)
array([ 0.25714286,  0.37142857,  0.34285714,  0.17142857, -0.14285714])
>>> savgol_coeffs(5, 2, pos=3, use='dot')
array([-0.14285714,  0.17142857,  0.34285714,  0.37142857,  0.25714286])
```

x contains data from the parabola x = t**2, sampled at t = -1, 0, 1, 2, 3. *c* holds the coefficients that will compute the derivative at the last position. When dotted with *x* the result should be 6.

```
>>> x = np.array([1, 0, 1, 4, 9])
>>> c = savgol_coeffs(5, 2, pos=4, deriv=1, use='dot')
>>> c.dot(x)
6.0
```

scipy.signal.remez

scipy.signal.**remez**(*numtaps*, *bands*, *desired*, *weight=None*, *Hz=None*, *type='bandpass'*, *maxiter=25*, *grid_density=16*, *fs=None*)

Calculate the minimax optimal filter using the Remez exchange algorithm.

Calculate the filter-coefficients for the finite impulse response (FIR) filter whose transfer function minimizes the maximum error between the desired gain and the realized gain in the specified frequency bands using the Remez exchange algorithm.

Parameters

numtaps [int] The desired number of taps in the filter. The number of taps is the number of terms in the filter, or the filter order plus one.

bands [array_like] A monotonic sequence containing the band edges. All elements must be non-negative and less than half the sampling frequency as given by *fs*.

desired [array_like] A sequence half the size of bands containing the desired gain in each of the specified bands.

weight [array_like, optional] A relative weighting to give to each band region. The length of *weight* has to be half the length of *bands*.

Hz [scalar, optional] *Deprecated. Use `fs` instead.* The sampling frequency in Hz. Default is 1.

type [{'bandpass', 'differentiator', 'hilbert'}, optional] The type of filter:
- 'bandpass' : flat response in bands. This is the default.
- 'differentiator' : frequency proportional response in bands.
- **'hilbert'** [filter with odd symmetry, that is, type III] (for even order) or type IV (for odd order) linear phase filters.

maxiter [int, optional] Maximum number of iterations of the algorithm. Default is 25.

grid_density [int, optional] Grid density. The dense grid used in *remez* is of size `(numtaps + 1) * grid_density`. Default is 16.

fs [float, optional] The sampling frequency of the signal. Default is 1.

Returns

out [ndarray] A rank-1 array containing the coefficients of the optimal (in a minimax sense) filter.

Examples

In these examples *remez* gets used creating a bandpass, bandstop, lowpass and highpass filter. The used parameters are the filter order, an array with according frequency boundaries, the desired attenuation values and the sampling frequency. Using *freqz* the corresponding frequency response gets calculated and plotted.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> def plot_response(fs, w, h, title):
...     "Utility function to plot response functions"
...     fig = plt.figure()
...     ax = fig.add_subplot(111)
...     ax.plot(0.5*fs*w/np.pi, 20*np.log10(np.abs(h)))
...     ax.set_ylim(-40, 5)
...     ax.set_xlim(0, 0.5*fs)
...     ax.grid(True)
...     ax.set_xlabel('Frequency (Hz)')
...     ax.set_ylabel('Gain (dB)')
...     ax.set_title(title)
```

This example shows a steep low pass transition according to the small transition width and high filter order:

```
>>> fs = 22050.0       # Sample rate, Hz
>>> cutoff = 8000.0    # Desired cutoff frequency, Hz
>>> trans_width = 100  # Width of transition from pass band to stop band,␣
↪Hz
>>> numtaps = 400      # Size of the FIR filter.
>>> taps = signal.remez(numtaps, [0, cutoff, cutoff + trans_width, 0.
↪5*fs], [1, 0], Hz=fs)
>>> w, h = signal.freqz(taps, [1], worN=2000)
>>> plot_response(fs, w, h, "Low-pass Filter")
```

This example shows a high pass filter:

```
>>> fs = 22050.0       # Sample rate, Hz
>>> cutoff = 2000.0    # Desired cutoff frequency, Hz
>>> trans_width = 250  # Width of transition from pass band to stop band,␣
↪Hz
>>> numtaps = 125      # Size of the FIR filter.
>>> taps = signal.remez(numtaps, [0, cutoff - trans_width, cutoff, 0.
↪5*fs],
...                     [0, 1], Hz=fs)
>>> w, h = signal.freqz(taps, [1], worN=2000)
>>> plot_response(fs, w, h, "High-pass Filter")
```

For a signal sampled with 22 kHz a bandpass filter with a pass band of 2-5 kHz gets calculated using the Remez algorithm. The transition width is 260 Hz and the filter order 10:

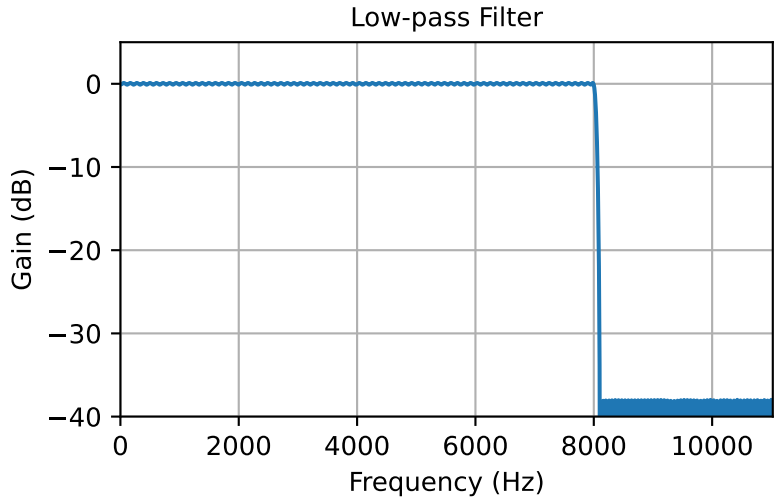
```
>>> fs = 22000.0         # Sample rate, Hz
>>> band = [2000, 5000]  # Desired pass band, Hz
>>> trans_width = 260    # Width of transition from pass band to stop␣
↪band, Hz
>>> numtaps = 10        # Size of the FIR filter.
>>> edges = [0, band[0] - trans_width, band[0], band[1],
...          band[1] + trans_width, 0.5*fs]
>>> taps = signal.remez(numtaps, edges, [0, 1, 0], Hz=fs)
>>> w, h = signal.freqz(taps, [1], worN=2000)
>>> plot_response(fs, w, h, "Band-pass Filter")
```

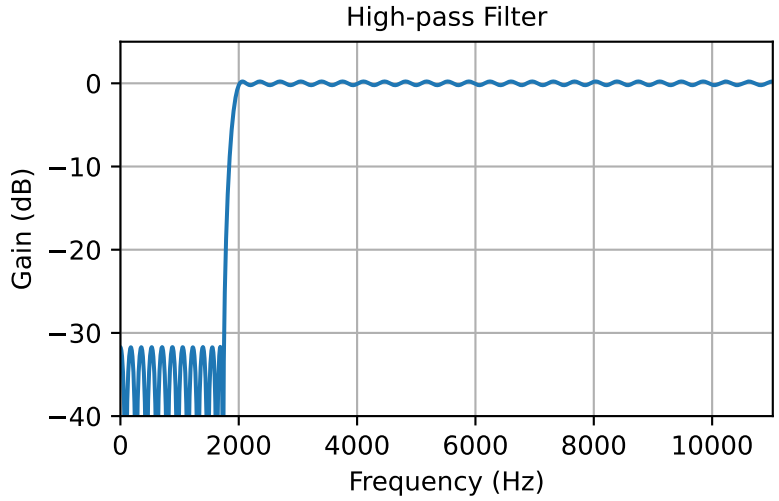
It can be seen that for this bandpass filter, the low order leads to higher ripple and less steep transitions. There is very low attenuation in the stop band and little overshoot in the pass band. Of course the desired gain can be better approximated with a higher filter order.

The next example shows a bandstop filter. Because of the high filter order the transition is quite steep:

```
>>> fs = 20000.0         # Sample rate, Hz
>>> band = [6000, 8000]  # Desired stop band, Hz
>>> trans_width = 200    # Width of transition from pass band to stop␣
↪band, Hz
>>> numtaps = 175        # Size of the FIR filter.
>>> edges = [0, band[0] - trans_width, band[0], band[1], band[1] + trans_
↪width, 0.5*fs]
>>> taps = signal.remez(numtaps, edges, [1, 0, 1], Hz=fs)
>>> w, h = signal.freqz(taps, [1], worN=2000)
>>> plot_response(fs, w, h, "Band-stop Filter")
```

```
>>> plt.show()
```





scipy.signal.unique_roots

`scipy.signal.`**`unique_roots`**(*p*, *tol=0.001*, *rtype='min'*)

Determine unique roots and their multiplicities from a list of roots.

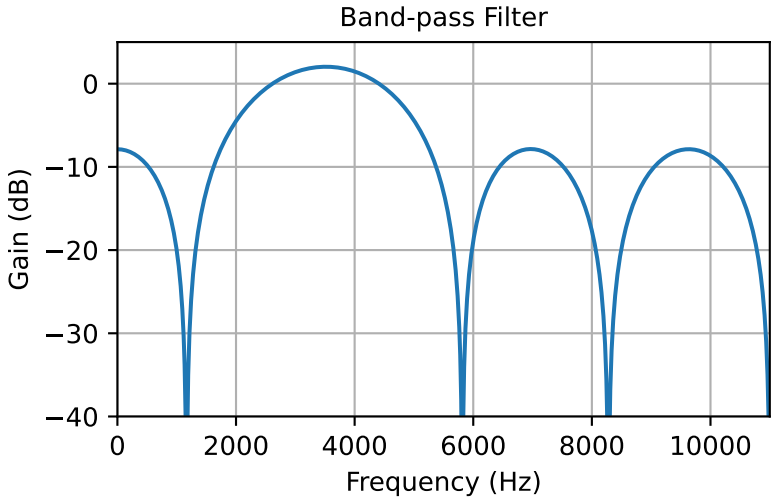
Parameters

p [array_like] The list of roots.

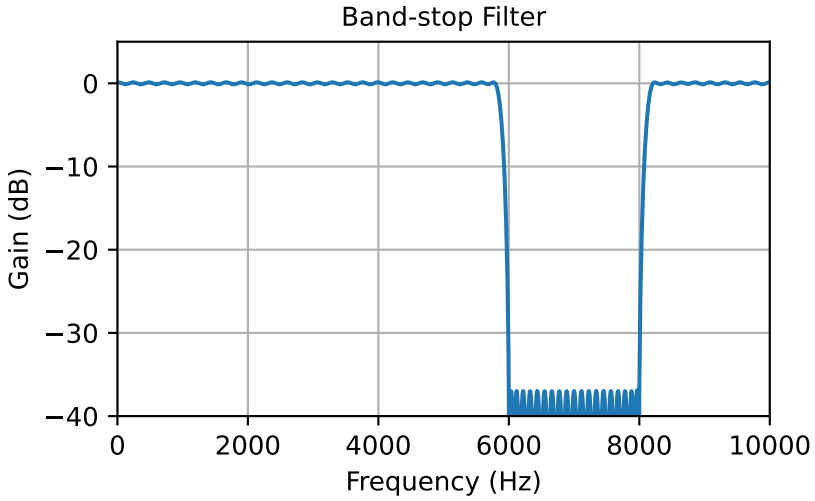
tol [float, optional] The tolerance for two roots to be considered equal in terms of the distance between them. Default is 1e-3. Refer to Notes about the details on roots grouping.

rtype [{'max', 'maximum', 'min', 'minimum', 'avg', 'mean'}, optional] How to determine the returned root if multiple roots are within *tol* of each other.

- 'max', 'maximum': pick the maximum of those roots
- 'min', 'minimum': pick the minimum of those roots



Band-pass Filter
Gain (dB)
0
−10
−20
−30
−40
0
2000
4000
6000
8000
10000
Frequency (Hz)



Band-stop Filter
Gain (dB)
0
−10
−20
−30
−40
0
2000
4000
6000
8000
10000
Frequency (Hz)

- 'avg', 'mean': take the average of those roots

When finding minimum or maximum among complex roots they are compared first by the real part and then by the imaginary part.

Returns

unique [ndarray] The list of unique roots.

multiplicity [ndarray] The multiplicity of each root.

Notes

If we have 3 roots `a`, `b` and `c`, such that `a` is close to `b` and `b` is close to `c` (distance is less than *tol*), then it doesn't necessarily mean that `a` is close to `c`. It means that roots grouping is not unique. In this function we use "greedy" grouping going through the roots in the order they are given in the input *p*.

This utility function is not specific to roots but can be used for any sequence of values for which uniqueness and multiplicity has to be determined. For a more general routine, see `numpy.unique`.

Examples

```
>>> from scipy import signal
>>> vals = [0, 1.3, 1.31, 2.8, 1.25, 2.2, 10.3]
>>> uniq, mult = signal.unique_roots(vals, tol=2e-2, rtype='avg')
```

Check which roots have multiplicity larger than 1:

```
>>> uniq[mult > 1]
array([ 1.305])
```

scipy.signal.residue

`scipy.signal.`**`residue`**(*b*, *a*, *tol=0.001*, *rtype='avg'*)

Compute partial-fraction expansion of b(s) / a(s).

If *M* is the degree of numerator *b* and *N* the degree of denominator *a*:

```
        b(s)     b[0] s**(M) + b[1] s**(M-1) + ... + b[M]
H(s) = ------ = ----------------------------------------
        a(s)     a[0] s**(N) + a[1] s**(N-1) + ... + a[N]
```

then the partial-fraction expansion H(s) is defined as:

```
    r[0]        r[1]              r[-1]
= -------- + -------- + ... + --------- + k(s)
  (s-p[0])    (s-p[1])          (s-p[-1])
```

If there are any repeated roots (closer together than *tol*), then H(s) has terms like:

```
  r[i]       r[i+1]               r[i+n-1]
-------- + ----------- + ... + -----------
(s-p[i])   (s-p[i])**2           (s-p[i])**n
```

This function is used for polynomials in positive powers of s or z, such as analog filters or digital filters in controls engineering. For negative powers of z (typical for digital filters in DSP), use *residuez*.

See Notes for details about the algorithm.

Parameters

b	[array_like] Numerator polynomial coefficients.
a	[array_like] Denominator polynomial coefficients.
tol	[float, optional] The tolerance for two roots to be considered equal in terms of the distance between them. Default is 1e-3. See *unique_roots* for further details.
rtype	[{'avg', 'min', 'max'}, optional] Method for computing a root to represent a group of identical roots. Default is 'avg'. See *unique_roots* for further details.

Returns

r	[ndarray] Residues corresponding to the poles. For repeated poles, the residues are ordered to correspond to ascending by power fractions.
p	[ndarray] Poles ordered by magnitude in ascending order.
k	[ndarray] Coefficients of the direct polynomial term.

See also:

invres, **residuez**, ***numpy.poly***, **unique_roots**

Notes

The "deflation through subtraction" algorithm is used for computations — method 6 in [1].

The form of partial fraction expansion depends on poles multiplicity in the exact mathematical sense. However there is no way to exactly determine multiplicity of roots of a polynomial in numerical computing. Thus you should think of the result of *residue* with given *tol* as partial fraction expansion computed for the denominator composed of the computed poles with empirically determined multiplicity. The choice of *tol* can drastically change the result if there are close poles.

References

[1]

scipy.signal.residuez

scipy.signal.**residuez**(*b*, *a*, *tol=0.001*, *rtype='avg'*)

Compute partial-fraction expansion of b(z) / a(z).

If *M* is the degree of numerator *b* and *N* the degree of denominator *a*:

```
        b(z)     b[0] + b[1] z**(-1) + ... + b[M] z**(-M)
H(z) = ------ = ------------------------------------------
        a(z)     a[0] + a[1] z**(-1) + ... + a[N] z**(-N)
```

then the partial-fraction expansion H(z) is defined as:

```
         r[0]                   r[-1]
= --------------- + ... + ---------------- + k[0] + k[1]z**(-1) ...
  (1-p[0]z**(-1))         (1-p[-1]z**(-1))
```

If there are any repeated roots (closer than *tol*), then the partial fraction expansion has terms like:

```
     r[i]               r[i+1]                      r[i+n-1]
-------------- + ------------------ + ... + ------------------
(1-p[i]z**(-1))   (1-p[i]z**(-1))**2          (1-p[i]z**(-1))**n
```

This function is used for polynomials in negative powers of z, such as digital filters in DSP. For positive powers, use *residue*.

See Notes of *residue* for details about the algorithm.

Parameters

b	[array_like] Numerator polynomial coefficients.
a	[array_like] Denominator polynomial coefficients.
tol	[float, optional] The tolerance for two roots to be considered equal in terms of the distance between them. Default is 1e-3. See *unique_roots* for further details.
rtype	[{'avg', 'min', 'max'}, optional] Method for computing a root to represent a group of identical roots. Default is 'avg'. See *unique_roots* for further details.

Returns

r	[ndarray] Residues corresponding to the poles. For repeated poles, the residues are ordered to correspond to ascending by power fractions.
p	[ndarray] Poles ordered by magnitude in ascending order.
k	[ndarray] Coefficients of the direct polynomial term.

See also:

invresz, **residue**, **unique_roots**

scipy.signal.invres

scipy.signal.**invres**(*r*, *p*, *k*, *tol=0.001*, *rtype='avg'*)

Compute b(s) and a(s) from partial fraction expansion.

If *M* is the degree of numerator *b* and *N* the degree of denominator *a*:

```
        b(s)     b[0] s**(M) + b[1] s**(M-1) + ... + b[M]
H(s) = ------ = ----------------------------------------
        a(s)     a[0] s**(N) + a[1] s**(N-1) + ... + a[N]
```

then the partial-fraction expansion H(s) is defined as:

```
    r[0]        r[1]              r[-1]
= -------- + -------- + ... + --------- + k(s)
  (s-p[0])    (s-p[1])          (s-p[-1])
```

If there are any repeated roots (closer together than *tol*), then H(s) has terms like:

```
  r[i]       r[i+1]               r[i+n-1]
-------- + ----------- + ... + -----------
(s-p[i])   (s-p[i])**2           (s-p[i])**n
```

This function is used for polynomials in positive powers of s or z, such as analog filters or digital filters in controls engineering. For negative powers of z (typical for digital filters in DSP), use *invresz*.

Parameters

r	[array_like] Residues corresponding to the poles. For repeated poles, the residues must be ordered to correspond to ascending by power fractions.

p [array_like] Poles. Equal poles must be adjacent.
k [array_like] Coefficients of the direct polynomial term.
tol [float, optional] The tolerance for two roots to be considered equal in terms of the distance between them. Default is 1e-3. See *unique_roots* for further details.
rtype [{'avg', 'min', 'max'}, optional] Method for computing a root to represent a group of identical roots. Default is 'avg'. See *unique_roots* for further details.

Returns

b [ndarray] Numerator polynomial coefficients.
a [ndarray] Denominator polynomial coefficients.

See also:

residue, invresz, unique_roots

scipy.signal.invresz

scipy.signal.**invresz**(*r*, *p*, *k*, *tol=0.001*, *rtype='avg'*)

Compute b(z) and a(z) from partial fraction expansion.

If *M* is the degree of numerator *b* and *N* the degree of denominator *a*:

```
        b(z)     b[0] + b[1] z**(-1) + ... + b[M] z**(-M)
H(z) = ------ = ----------------------------------------
        a(z)     a[0] + a[1] z**(-1) + ... + a[N] z**(-N)
```

then the partial-fraction expansion H(z) is defined as:

```
         r[0]                   r[-1]
= ---------------- + ... + ---------------- + k[0] + k[1]z**(-1) ...
  (1-p[0]z**(-1))         (1-p[-1]z**(-1))
```

If there are any repeated roots (closer than *tol*), then the partial fraction expansion has terms like:

```
     r[i]              r[i+1]                    r[i+n-1]
-------------- + ------------------ + ... + ------------------
(1-p[i]z**(-1))  (1-p[i]z**(-1))**2          (1-p[i]z**(-1))**n
```

This function is used for polynomials in negative powers of z, such as digital filters in DSP. For positive powers, use *invres*.

Parameters

r [array_like] Residues corresponding to the poles. For repeated poles, the residues must be ordered to correspond to ascending by power fractions.
p [array_like] Poles. Equal poles must be adjacent.
k [array_like] Coefficients of the direct polynomial term.
tol [float, optional] The tolerance for two roots to be considered equal in terms of the distance between them. Default is 1e-3. See *unique_roots* for further details.
rtype [{'avg', 'min', 'max'}, optional] Method for computing a root to represent a group of identical roots. Default is 'avg'. See *unique_roots* for further details.

Returns

b [ndarray] Numerator polynomial coefficients.
a [ndarray] Denominator polynomial coefficients.

scipy.signal.BadCoefficients

exception scipy.signal.**BadCoefficients**
Warning about badly conditioned filter coefficients

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

Lower-level filter design functions:

abcd_normalize([A, B, C, D])	Check state-space matrices and ensure they are 2-D.
band_stop_obj(wp, ind, passb, stopb, gpass, …)	Band Stop Objective Function for order minimization.
besselap(N[, norm])	Return (z,p,k) for analog prototype of an Nth-order Bessel filter.
buttap(N)	Return (z,p,k) for analog prototype of Nth-order Butterworth filter.
cheb1ap(N, rp)	Return (z,p,k) for Nth-order Chebyshev type I analog lowpass filter.
cheb2ap(N, rs)	Return (z,p,k) for Nth-order Chebyshev type I analog lowpass filter.
cmplx_sort(p)	Sort roots based on magnitude.
ellipap(N, rp, rs)	Return (z,p,k) of Nth-order elliptic analog lowpass filter.
lp2bp(b, a[, wo, bw])	Transform a lowpass filter prototype to a bandpass filter.
lp2bp_zpk(z, p, k[, wo, bw])	Transform a lowpass filter prototype to a bandpass filter.
lp2bs(b, a[, wo, bw])	Transform a lowpass filter prototype to a bandstop filter.
lp2bs_zpk(z, p, k[, wo, bw])	Transform a lowpass filter prototype to a bandstop filter.
lp2hp(b, a[, wo])	Transform a lowpass filter prototype to a highpass filter.
lp2hp_zpk(z, p, k[, wo])	Transform a lowpass filter prototype to a highpass filter.
lp2lp(b, a[, wo])	Transform a lowpass filter prototype to a different frequency.
lp2lp_zpk(z, p, k[, wo])	Transform a lowpass filter prototype to a different frequency.
normalize(b, a)	Normalize numerator/denominator of a continuous-time transfer function.

scipy.signal.abcd_normalize

scipy.signal.**abcd_normalize**(*A=None*, *B=None*, *C=None*, *D=None*)
Check state-space matrices and ensure they are 2-D.

If enough information on the system is provided, that is, enough properly-shaped arrays are passed to the function, the missing ones are built from this information, ensuring the correct number of rows and columns. Otherwise a ValueError is raised.

Parameters

A, B, C, D [array_like, optional] State-space matrices. All of them are None (missing) by default. See *ss2tf* for format.

Returns

A, B, C, D [array] Properly shaped state-space matrices.

Raises

ValueError

If not enough information on the system was provided.

scipy.signal.band_stop_obj

scipy.signal.**band_stop_obj**(*wp*, *ind*, *passb*, *stopb*, *gpass*, *gstop*, *type*)

Band Stop Objective Function for order minimization.

Returns the non-integer order for an analog band stop filter.

Parameters

wp	[scalar] Edge of passband *passb*.
ind	[int, {0, 1}] Index specifying which *passb* edge to vary (0 or 1).
passb	[ndarray] Two element sequence of fixed passband edges.
stopb	[ndarray] Two element sequence of fixed stopband edges.
gstop	[float] Amount of attenuation in stopband in dB.
gpass	[float] Amount of ripple in the passband in dB.
type	[{'butter', 'cheby', 'ellip'}] Type of filter.

Returns

n	[scalar] Filter order (possibly non-integer).

scipy.signal.besselap

scipy.signal.**besselap**(*N*, *norm='phase'*)

Return (z,p,k) for analog prototype of an Nth-order Bessel filter.

Parameters

N	[int] The order of the filter.
norm	[{'phase', 'delay', 'mag'}, optional] Frequency normalization:
	phase The filter is normalized such that the phase response reaches its midpoint at an angular (e.g., rad/s) cutoff frequency of 1. This happens for both low-pass and high-pass filters, so this is the "phase-matched" case. [6] The magnitude response asymptotes are the same as a Butterworth filter of the same order with a cutoff of *Wn*. This is the default, and matches MATLAB's implementation.
	delay The filter is normalized such that the group delay in the passband is 1 (e.g., 1 second). This is the "natural" type obtained by solving Bessel polynomials
	mag The filter is normalized such that the gain magnitude is -3 dB at angular frequency 1. This is called "frequency normalization" by Bond. [1]
	New in version 0.18.0.

Returns

z	[ndarray] Zeros of the transfer function. Is always an empty array.
p	[ndarray] Poles of the transfer function.
k	[scalar] Gain of the transfer function. For phase-normalized, this is always 1.

See also:

bessel

Filter design function using this prototype

Notes

To find the pole locations, approximate starting points are generated [2] for the zeros of the ordinary Bessel polynomial [3], then the Aberth-Ehrlich method [4] [5] is used on the Kv(x) Bessel function to calculate more accurate zeros, and these locations are then inverted about the unit circle.

References

[1], [2], [3], [4], [5], [6]

scipy.signal.buttap

`scipy.signal.`**`buttap`**(*N*)

Return (z,p,k) for analog prototype of Nth-order Butterworth filter.

The filter will have an angular (e.g., rad/s) cutoff frequency of 1.

See also:

`butter`

Filter design function using this prototype

scipy.signal.cheb1ap

`scipy.signal.`**`cheb1ap`**(*N*, *rp*)

Return (z,p,k) for Nth-order Chebyshev type I analog lowpass filter.

The returned filter prototype has *rp* decibels of ripple in the passband.

The filter's angular (e.g. rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first drops below `-rp`.

See also:

`cheby1`

Filter design function using this prototype

scipy.signal.cheb2ap

`scipy.signal.`**`cheb2ap`**(*N*, *rs*)

Return (z,p,k) for Nth-order Chebyshev type I analog lowpass filter.

The returned filter prototype has *rs* decibels of ripple in the stopband.

The filter's angular (e.g. rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first reaches `-rs`.

See also:

`cheby2`

Filter design function using this prototype

scipy.signal.cmplx_sort

scipy.signal.**cmplx_sort**(*p*)

Sort roots based on magnitude.

Parameters

p [array_like] The roots to sort, as a 1-D array.

Returns

p_sorted [ndarray] Sorted roots.
indx [ndarray] Array of indices needed to sort the input *p*.

Examples

```
>>> from scipy import signal
>>> vals = [1, 4, 1+1.j, 3]
>>> p_sorted, indx = signal.cmplx_sort(vals)
>>> p_sorted
array([1.+0.j, 1.+1.j, 3.+0.j, 4.+0.j])
>>> indx
array([0, 2, 3, 1])
```

scipy.signal.ellipap

scipy.signal.**ellipap**(*N*, *rp*, *rs*)

Return (z,p,k) of Nth-order elliptic analog lowpass filter.

The filter is a normalized prototype that has *rp* decibels of ripple in the passband and a stopband *rs* decibels down.

The filter's angular (e.g., rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first drops below `-rp`.

ellip

Filter design function using this prototype

References

[1], [2]

scipy.signal.lp2bp

scipy.signal.**lp2bp**(*b*, *a*, *wo=1.0*, *bw=1.0*)

Transform a lowpass filter prototype to a bandpass filter.

Return an analog band-pass filter with center frequency *wo* and bandwidth *bw* from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

Parameters

b [array_like] Numerator polynomial coefficients.
a [array_like] Denominator polynomial coefficients.
wo [float] Desired passband center, as angular frequency (e.g., rad/s). Defaults to no change.
bw [float] Desired passband width, as angular frequency (e.g., rad/s). Defaults to 1.

Returns

b	[array_like] Numerator polynomial coefficients of the transformed band-pass filter.
a	[array_like] Denominator polynomial coefficients of the transformed band-pass filter.

See also:

lp2lp, **lp2hp**, **lp2bs**, **bilinear**

lp2bp_zpk

Notes

This is derived from the s-plane substitution

$$s \to \frac{s^2 + {\omega_0}^2}{s \cdot \mathrm{BW}}$$

This is the "wideband" transformation, producing a passband with geometric (log frequency) symmetry about *wo*.

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> lp = signal.lti([1.0], [1.0, 1.0])
>>> bp = signal.lti(*signal.lp2bp(lp.num, lp.den))
>>> w, mag_lp, p_lp = lp.bode()
>>> w, mag_bp, p_bp = bp.bode(w)
```

```
>>> plt.plot(w, mag_lp, label='Lowpass')
>>> plt.plot(w, mag_bp, label='Bandpass')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.legend()
```

scipy.signal.lp2bp_zpk

scipy.signal.**lp2bp_zpk**(*z*, *p*, *k*, *wo=1.0*, *bw=1.0*)

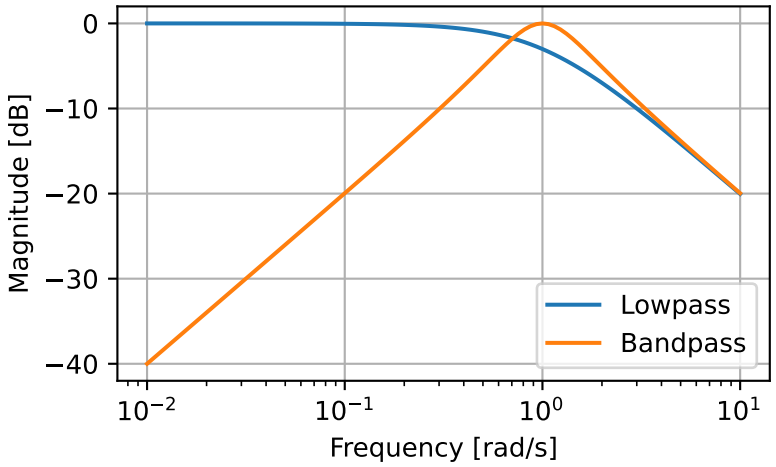
Transform a lowpass filter prototype to a bandpass filter.

Return an analog band-pass filter with center frequency *wo* and bandwidth *bw* from an analog low-pass filter prototype with unity cutoff frequency, using zeros, poles, and gain ('zpk') representation.

Parameters

z	[array_like] Zeros of the analog filter transfer function.
p	[array_like] Poles of the analog filter transfer function.
k	[float] System gain of the analog filter transfer function.
wo	[float] Desired passband center, as angular frequency (e.g., rad/s). Defaults to no change.
bw	[float] Desired passband width, as angular frequency (e.g., rad/s). Defaults to 1.

Returns



z	[ndarray] Zeros of the transformed band-pass filter transfer function.
p	[ndarray] Poles of the transformed band-pass filter transfer function.
k	[float] System gain of the transformed band-pass filter.

See also:

`lp2lp_zpk`, `lp2hp_zpk`, `lp2bs_zpk`, `bilinear`

`lp2bp`

Notes

This is derived from the s-plane substitution

$$s \rightarrow \frac{s^2 + {\omega_0}^2}{s \cdot \mathrm{BW}}$$

This is the “wideband” transformation, producing a passband with geometric (log frequency) symmetry about *wo*.

New in version 1.1.0.

scipy.signal.lp2bs

`scipy.signal.`**`lp2bs`**(*b*, *a*, *wo=1.0*, *bw=1.0*)

Transform a lowpass filter prototype to a bandstop filter.

Return an analog band-stop filter with center frequency *wo* and bandwidth *bw* from an analog low-pass filter prototype with unity cutoff frequency, in transfer function (‘ba’) representation.

Parameters

b	[array_like] Numerator polynomial coefficients.
a	[array_like] Denominator polynomial coefficients.
wo	[float] Desired stopband center, as angular frequency (e.g., rad/s). Defaults to no change.
bw	[float] Desired stopband width, as angular frequency (e.g., rad/s). Defaults to 1.

Returns

b	[array_like] Numerator polynomial coefficients of the transformed band-stop filter.

a [array_like] Denominator polynomial coefficients of the transformed band-stop filter.

See also:

`lp2lp`, `lp2hp`, `lp2bp`, `bilinear`

`lp2bs_zpk`

Notes

This is derived from the s-plane substitution

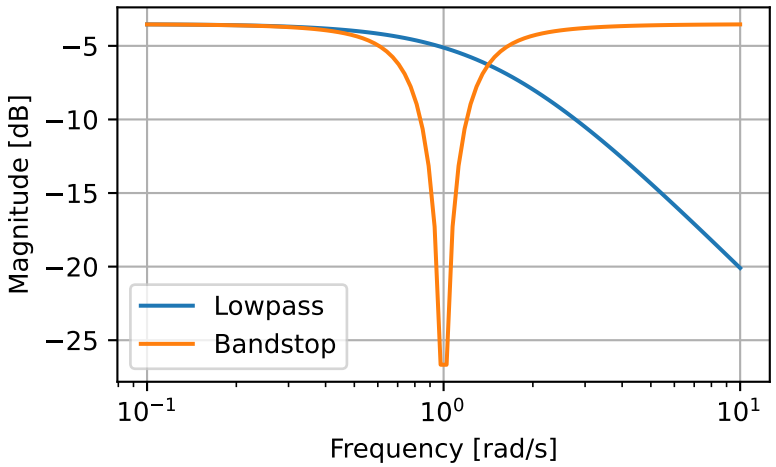
$$s \rightarrow \frac{s \cdot \mathrm{BW}}{s^2 + {\omega_0}^2}$$

This is the "wideband" transformation, producing a stopband with geometric (log frequency) symmetry about *wo*.

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> lp = signal.lti([1.0], [1.0, 1.5])
>>> bs = signal.lti(*signal.lp2bs(lp.num, lp.den))
>>> w, mag_lp, p_lp = lp.bode()
>>> w, mag_bs, p_bs = bs.bode(w)
>>> plt.plot(w, mag_lp, label='Lowpass')
>>> plt.plot(w, mag_bs, label='Bandstop')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.legend()
```



scipy.signal.lp2bs_zpk

scipy.signal.**lp2bs_zpk**(*z*, *p*, *k*, *wo=1.0*, *bw=1.0*)

Transform a lowpass filter prototype to a bandstop filter.

Return an analog band-stop filter with center frequency *wo* and stopband width *bw* from an analog low-pass filter prototype with unity cutoff frequency, using zeros, poles, and gain ('zpk') representation.

Parameters

z	[array_like] Zeros of the analog filter transfer function.
p	[array_like] Poles of the analog filter transfer function.
k	[float] System gain of the analog filter transfer function.
wo	[float] Desired stopband center, as angular frequency (e.g., rad/s). Defaults to no change.
bw	[float] Desired stopband width, as angular frequency (e.g., rad/s). Defaults to 1.

Returns

z	[ndarray] Zeros of the transformed band-stop filter transfer function.
p	[ndarray] Poles of the transformed band-stop filter transfer function.
k	[float] System gain of the transformed band-stop filter.

See also:

lp2lp_zpk, **lp2hp_zpk**, **lp2bp_zpk**, **bilinear**

lp2bs

Notes

This is derived from the s-plane substitution

$$s \rightarrow \frac{s \cdot \mathrm{BW}}{s^2 + \omega_0{}^2}$$

This is the "wideband" transformation, producing a stopband with geometric (log frequency) symmetry about *wo*.

New in version 1.1.0.

scipy.signal.lp2hp

scipy.signal.**lp2hp**(*b*, *a*, *wo=1.0*)

Transform a lowpass filter prototype to a highpass filter.

Return an analog high-pass filter with cutoff frequency *wo* from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

Parameters

b	[array_like] Numerator polynomial coefficients.
a	[array_like] Denominator polynomial coefficients.
wo	[float] Desired cutoff, as angular frequency (e.g., rad/s). Defaults to no change.

Returns

b	[array_like] Numerator polynomial coefficients of the transformed high-pass filter.
a	[array_like] Denominator polynomial coefficients of the transformed high-pass filter.

See also:

lp2lp, **lp2bp**, **lp2bs**, **bilinear**

lp2hp_zpk

Notes

This is derived from the s-plane substitution

$$s \to \frac{\omega_0}{s}$$

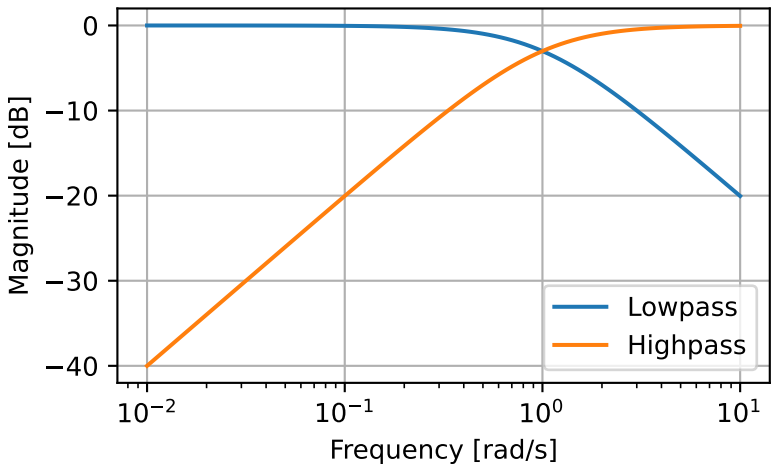
This maintains symmetry of the lowpass and highpass responses on a logarithmic scale.

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> lp = signal.lti([1.0], [1.0, 1.0])
>>> hp = signal.lti(*signal.lp2hp(lp.num, lp.den))
>>> w, mag_lp, p_lp = lp.bode()
>>> w, mag_hp, p_hp = hp.bode(w)
```

```
>>> plt.plot(w, mag_lp, label='Lowpass')
>>> plt.plot(w, mag_hp, label='Highpass')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.legend()
```



scipy.signal.lp2hp_zpk

scipy.signal.**lp2hp_zpk**(*z*, *p*, *k*, *wo=1.0*)

Transform a lowpass filter prototype to a highpass filter.

Return an analog high-pass filter with cutoff frequency *wo* from an analog low-pass filter prototype with unity cutoff frequency, using zeros, poles, and gain ('zpk') representation.

Parameters

z	[array_like] Zeros of the analog filter transfer function.
p	[array_like] Poles of the analog filter transfer function.
k	[float] System gain of the analog filter transfer function.
wo	[float] Desired cutoff, as angular frequency (e.g., rad/s). Defaults to no change.

Returns

z	[ndarray] Zeros of the transformed high-pass filter transfer function.
p	[ndarray] Poles of the transformed high-pass filter transfer function.
k	[float] System gain of the transformed high-pass filter.

See also:

lp2lp_zpk, **lp2bp_zpk**, **lp2bs_zpk**, **bilinear**

lp2hp

Notes

This is derived from the s-plane substitution

$$s \rightarrow \frac{\omega_0}{s}$$

This maintains symmetry of the lowpass and highpass responses on a logarithmic scale.

New in version 1.1.0.

scipy.signal.lp2lp

scipy.signal.**lp2lp**(*b*, *a*, *wo=1.0*)

Transform a lowpass filter prototype to a different frequency.

Return an analog low-pass filter with cutoff frequency *wo* from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

Parameters

b	[array_like] Numerator polynomial coefficients.
a	[array_like] Denominator polynomial coefficients.
wo	[float] Desired cutoff, as angular frequency (e.g. rad/s). Defaults to no change.

Returns

b	[array_like] Numerator polynomial coefficients of the transformed low-pass filter.
a	[array_like] Denominator polynomial coefficients of the transformed low-pass filter.

See also:

lp2hp, **lp2bp**, **lp2bs**, **bilinear**

lp2lp_zpk

Notes

This is derived from the s-plane substitution

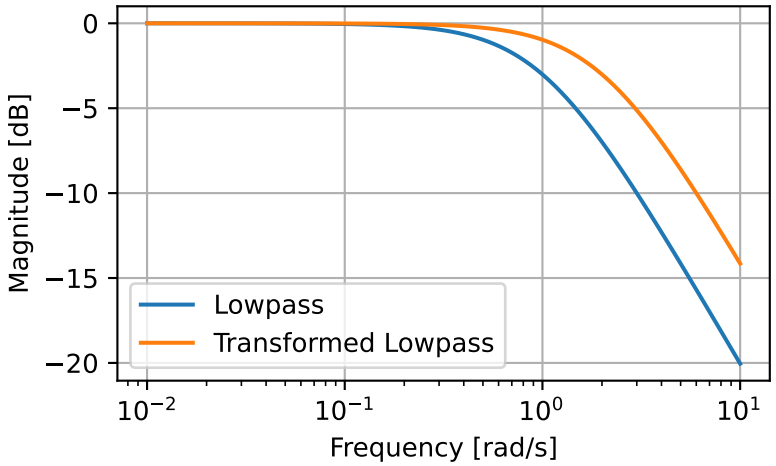
$$s \rightarrow \frac{s}{\omega_0}$$

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> lp = signal.lti([1.0], [1.0, 1.0])
>>> lp2 = signal.lti(*signal.lp2lp(lp.num, lp.den, 2))
>>> w, mag_lp, p_lp = lp.bode()
>>> w, mag_lp2, p_lp2 = lp2.bode(w)
```

```
>>> plt.plot(w, mag_lp, label='Lowpass')
>>> plt.plot(w, mag_lp2, label='Transformed Lowpass')
>>> plt.semilogx()
>>> plt.grid()
>>> plt.xlabel('Frequency [rad/s]')
>>> plt.ylabel('Magnitude [dB]')
>>> plt.legend()
```



scipy.signal.lp2lp_zpk

scipy.signal.**lp2lp_zpk**(*z*, *p*, *k*, *wo=1.0*)

Transform a lowpass filter prototype to a different frequency.

Return an analog low-pass filter with cutoff frequency *wo* from an analog low-pass filter prototype with unity cutoff frequency, using zeros, poles, and gain ('zpk') representation.

Parameters

z	[array_like] Zeros of the analog filter transfer function.
p	[array_like] Poles of the analog filter transfer function.
k	[float] System gain of the analog filter transfer function.
wo	[float] Desired cutoff, as angular frequency (e.g., rad/s). Defaults to no change.

Returns

z	[ndarray] Zeros of the transformed low-pass filter transfer function.
p	[ndarray] Poles of the transformed low-pass filter transfer function.
k	[float] System gain of the transformed low-pass filter.

See also:

lp2hp_zpk, **lp2bp_zpk**, **lp2bs_zpk**, **bilinear**

lp2lp

Notes

This is derived from the s-plane substitution

$$s \rightarrow \frac{s}{\omega_0}$$

New in version 1.1.0.

scipy.signal.normalize

scipy.signal.**normalize**(*b*, *a*)

Normalize numerator/denominator of a continuous-time transfer function.

If values of *b* are too close to 0, they are removed. In that case, a BadCoefficients warning is emitted.

Parameters

b: array_like
: Numerator of the transfer function. Can be a 2-D array to normalize multiple transfer functions.

a: array_like
: Denominator of the transfer function. At most 1-D.

Returns

num: array
: The numerator of the normalized transfer function. At least a 1-D array. A 2-D array if the input *num* is a 2-D array.

den: 1-D array
: The denominator of the normalized transfer function.

Notes

Coefficients for both the numerator and denominator should be specified in descending exponent order (e.g., `s^2 + 3s + 5` would be represented as `[1, 3, 5]`).

Matlab-style IIR filter design

butter(N, Wn[, btype, analog, output, fs])	Butterworth digital and analog filter design.
buttord(wp, ws, gpass, gstop[, analog, fs])	Butterworth filter order selection.
cheby1(N, rp, Wn[, btype, analog, output, fs])	Chebyshev type I digital and analog filter design.
cheb1ord(wp, ws, gpass, gstop[, analog, fs])	Chebyshev type I filter order selection.
cheby2(N, rs, Wn[, btype, analog, output, fs])	Chebyshev type II digital and analog filter design.
cheb2ord(wp, ws, gpass, gstop[, analog, fs])	Chebyshev type II filter order selection.
ellip(N, rp, rs, Wn[, btype, analog, output, fs])	Elliptic (Cauer) digital and analog filter design.
ellipord(wp, ws, gpass, gstop[, analog, fs])	Elliptic (Cauer) filter order selection.
bessel(N, Wn[, btype, analog, output, norm, fs])	Bessel/Thomson digital and analog filter design.
iirnotch(w0, Q[, fs])	Design second-order IIR notch digital filter.
iirpeak(w0, Q[, fs])	Design second-order IIR peak (resonant) digital filter.
iircomb(w0, Q[, ftype, fs])	Design IIR notching or peaking digital comb filter.

scipy.signal.butter

`scipy.signal.`**`butter`**(*N*, *Wn*, *btype='low'*, *analog=False*, *output='ba'*, *fs=None*)

Butterworth digital and analog filter design.

Design an Nth-order digital or analog Butterworth filter and return the filter coefficients.

Parameters

N [int] The order of the filter.

Wn [array_like] The critical frequency or frequencies. For lowpass and highpass filters, Wn is a scalar; for bandpass and bandstop filters, Wn is a length-2 sequence.
For a Butterworth filter, this is the point at which the gain drops to 1/sqrt(2) that of the passband (the "-3 dB point").
For digital filters, *Wn* are in the same units as *fs*. By default, *fs* is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (*Wn* is thus in half-cycles / sample.)
For analog filters, *Wn* is an angular frequency (e.g. rad/s).

btype [{'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional] The type of filter. Default is 'lowpass'.

analog [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

output [{'ba', 'zpk', 'sos'}, optional] Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba' for backwards compatibility, but 'sos' should be used for general-purpose filtering.

fs [float, optional] The sampling frequency of the digital system.
New in version 1.2.0.

Returns

b, a [ndarray, ndarray] Numerator (*b*) and denominator (*a*) polynomials of the IIR filter. Only returned if `output='ba'`.

z, p, k [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

sos [ndarray] Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

See also:

`buttord`, `buttap`

Notes

The Butterworth filter has maximally flat frequency response in the passband.

The `'sos'` output parameter was added in 0.16.0.

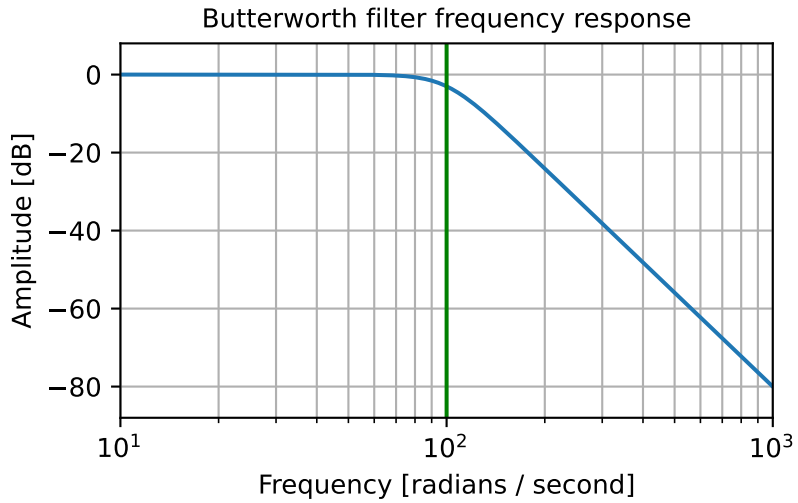
If the transfer function form `[b, a]` is requested, numerical problems can occur since the conversion between roots and the polynomial coefficients is a numerically sensitive operation, even for N >= 4. It is recommended to work with the SOS representation.

Examples

Design an analog filter and plot its frequency response, showing the critical points:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> b, a = signal.butter(4, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Butterworth filter frequency response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.show()
```

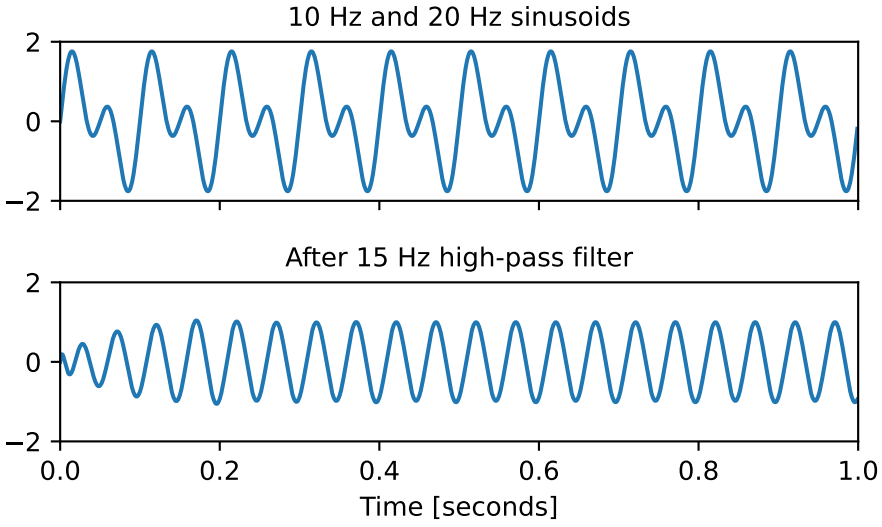


Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz

```
>>> t = np.linspace(0, 1, 1000, False)  # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
>>> ax1.set_title('10 Hz and 20 Hz sinusoids')
>>> ax1.axis([0, 1, -2, 2])
```

Design a digital high-pass filter at 15 Hz to remove the 10 Hz tone, and apply it to the signal. (It's recommended to use second-order sections format when filtering, to avoid numerical error with transfer function (`ba`) format):

```
>>> sos = signal.butter(10, 15, 'hp', fs=1000, output='sos')
>>> filtered = signal.sosfilt(sos, sig)
>>> ax2.plot(t, filtered)
>>> ax2.set_title('After 15 Hz high-pass filter')
>>> ax2.axis([0, 1, -2, 2])
>>> ax2.set_xlabel('Time [seconds]')
>>> plt.tight_layout()
>>> plt.show()
```



scipy.signal.buttord

`scipy.signal.`**`buttord`**(*wp*, *ws*, *gpass*, *gstop*, *analog=False*, *fs=None*)

Butterworth filter order selection.

Return the order of the lowest order digital or analog Butterworth filter that loses no more than *gpass* dB in the passband and has at least *gstop* dB attenuation in the stopband.

Parameters

wp, ws [float] Passband and stopband edge frequencies.
For digital filters, these are in the same units as *fs*. By default, *fs* is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (*wp* and *ws* are thus in half-cycles / sample.) For example:

- Lowpass: wp = 0.2, ws = 0.3
- Highpass: wp = 0.3, ws = 0.2
- Bandpass: wp = [0.2, 0.5], ws = [0.1, 0.6]

- Bandstop: wp = [0.1, 0.6], ws = [0.2, 0.5]

For analog filters, *wp* and *ws* are angular frequencies (e.g., rad/s).

gpass [float] The maximum loss in the passband (dB).

gstop [float] The minimum attenuation in the stopband (dB).

analog [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

fs [float, optional] The sampling frequency of the digital system.
New in version 1.2.0.

Returns

ord [int] The lowest order for a Butterworth filter which meets specs.

wn [ndarray or float] The Butterworth natural frequency (i.e. the "3dB frequency"). Should be used with `butter` to give filter results. If *fs* is specified, this is in the same units, and *fs* must also be passed to `butter`.

cheb1ord

Find order and critical points from passband and stopband spec

cheb2ord, **ellipord**

iirfilter

General filter design using order and critical frequencies

iirdesign

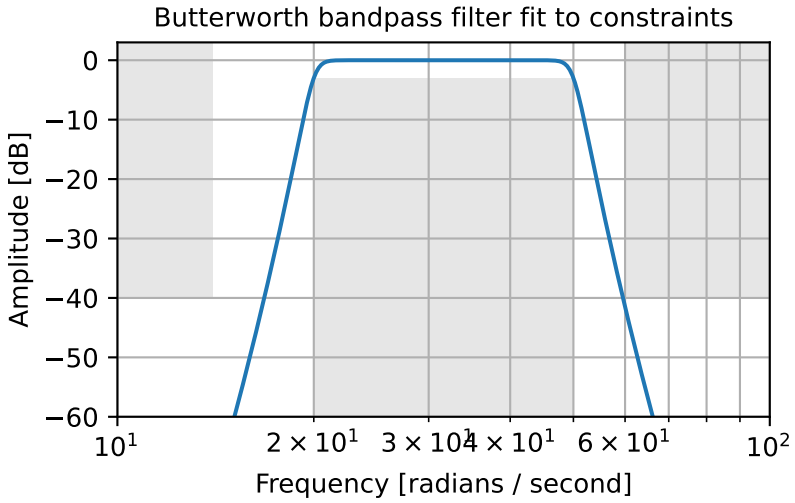
General filter design using passband and stopband spec

Examples

Design an analog bandpass filter with passband within 3 dB from 20 to 50 rad/s, while rejecting at least -40 dB below 14 and above 60 rad/s. Plot its frequency response, showing the passband and stopband constraints in gray.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> N, Wn = signal.buttord([20, 50], [14, 60], 3, 40, True)
>>> b, a = signal.butter(N, Wn, 'band', True)
>>> w, h = signal.freqs(b, a, np.logspace(1, 2, 500))
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Butterworth bandpass filter fit to constraints')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([1,  14,  14,   1], [-40, -40, 99, 99], '0.9', lw=0) # stop
>>> plt.fill([20, 20,  50,  50], [-99, -3, -3, -99], '0.9', lw=0) # pass
>>> plt.fill([60, 60, 1e9, 1e9], [99, -40, -40, 99], '0.9', lw=0) # stop
>>> plt.axis([10, 100, -60, 3])
>>> plt.show()
```



scipy.signal.cheby1

`scipy.signal.`**`cheby1`**(*N*, *rp*, *Wn*, *btype='low'*, *analog=False*, *output='ba'*, *fs=None*)

Chebyshev type I digital and analog filter design.

Design an Nth-order digital or analog Chebyshev type I filter and return the filter coefficients.

Parameters

N	[int] The order of the filter.
rp	[float] The maximum ripple allowed below unity gain in the passband. Specified in decibels, as a positive number.
Wn	[array_like] A scalar or length-2 sequence giving the critical frequencies. For Type I filters, this is the point in the transition band at which the gain first drops below *-rp*. For digital filters, *Wn* are in the same units as *fs*. By default, *fs* is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (*Wn* is thus in half-cycles / sample.) For analog filters, *Wn* is an angular frequency (e.g., rad/s).
btype	[{'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional] The type of filter. Default is 'lowpass'.
analog	[bool, optional] When True, return an analog filter, otherwise a digital filter is returned.
output	[{'ba', 'zpk', 'sos'}, optional] Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba' for backwards compatibility, but 'sos' should be used for general-purpose filtering.
fs	[float, optional] The sampling frequency of the digital system. New in version 1.2.0.

Returns

b, a	[ndarray, ndarray] Numerator (*b*) and denominator (*a*) polynomials of the IIR filter. Only returned if `output='ba'`.
z, p, k	[ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.
sos	[ndarray] Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

See also:

cheb1ord, **cheb1ap**

Notes

The Chebyshev type I filter maximizes the rate of cutoff between the frequency response's passband and stopband, at the expense of ripple in the passband and increased ringing in the step response.

Type I filters roll off faster than Type II (*cheby2*), but Type II filters do not have any ripple in the passband.

The equiripple passband has N maxima or minima (for example, a 5th-order filter has 3 maxima and 2 minima). Consequently, the DC gain is unity for odd-order filters, or -rp dB for even-order filters.

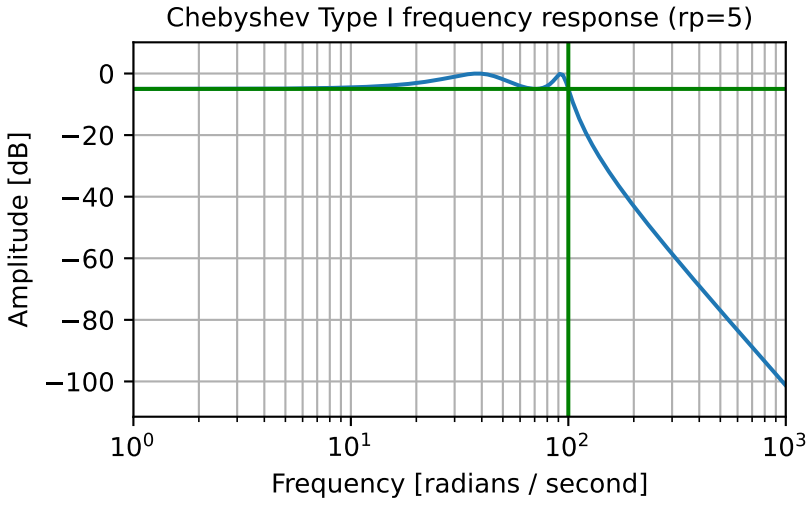
The `'sos'` output parameter was added in 0.16.0.

Examples

Design an analog filter and plot its frequency response, showing the critical points:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> b, a = signal.cheby1(4, 5, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev Type I frequency response (rp=5)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-5, color='green') # rp
>>> plt.show()
```

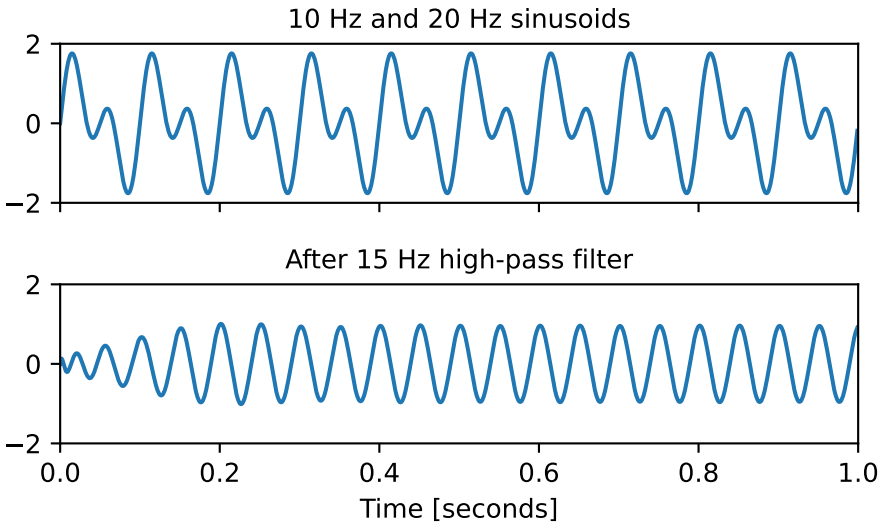


Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz

```
>>> t = np.linspace(0, 1, 1000, False)  # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
>>> ax1.set_title('10 Hz and 20 Hz sinusoids')
>>> ax1.axis([0, 1, -2, 2])
```

Design a digital high-pass filter at 15 Hz to remove the 10 Hz tone, and apply it to the signal. (It's recommended to use second-order sections format when filtering, to avoid numerical error with transfer function (`ba`) format):

```
>>> sos = signal.cheby1(10, 1, 15, 'hp', fs=1000, output='sos')
>>> filtered = signal.sosfilt(sos, sig)
>>> ax2.plot(t, filtered)
>>> ax2.set_title('After 15 Hz high-pass filter')
>>> ax2.axis([0, 1, -2, 2])
>>> ax2.set_xlabel('Time [seconds]')
>>> plt.tight_layout()
>>> plt.show()
```



scipy.signal.cheb1ord

`scipy.signal.`**`cheb1ord`**(*wp*, *ws*, *gpass*, *gstop*, *analog=False*, *fs=None*)

Chebyshev type I filter order selection.

Return the order of the lowest order digital or analog Chebyshev Type I filter that loses no more than *gpass* dB in the passband and has at least *gstop* dB attenuation in the stopband.

Parameters

wp, ws [float] Passband and stopband edge frequencies.
For digital filters, these are in the same units as *fs*. By default, *fs* is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (*wp* and *ws* are thus in half-cycles / sample.) For example:

- Lowpass: wp = 0.2, ws = 0.3
- Highpass: wp = 0.3, ws = 0.2
- Bandpass: wp = [0.2, 0.5], ws = [0.1, 0.6]

- Bandstop: wp = [0.1, 0.6], ws = [0.2, 0.5]

For analog filters, *wp* and *ws* are angular frequencies (e.g., rad/s).

gpass [float] The maximum loss in the passband (dB).

gstop [float] The minimum attenuation in the stopband (dB).

analog [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

fs [float, optional] The sampling frequency of the digital system.
New in version 1.2.0.

Returns

ord [int] The lowest order for a Chebyshev type I filter that meets specs.

wn [ndarray or float] The Chebyshev natural frequency (the "3dB frequency") for use with *cheby1* to give filter results. If *fs* is specified, this is in the same units, and *fs* must also be passed to *cheby1*.

General filter design using order and critical frequencies

iirdesign

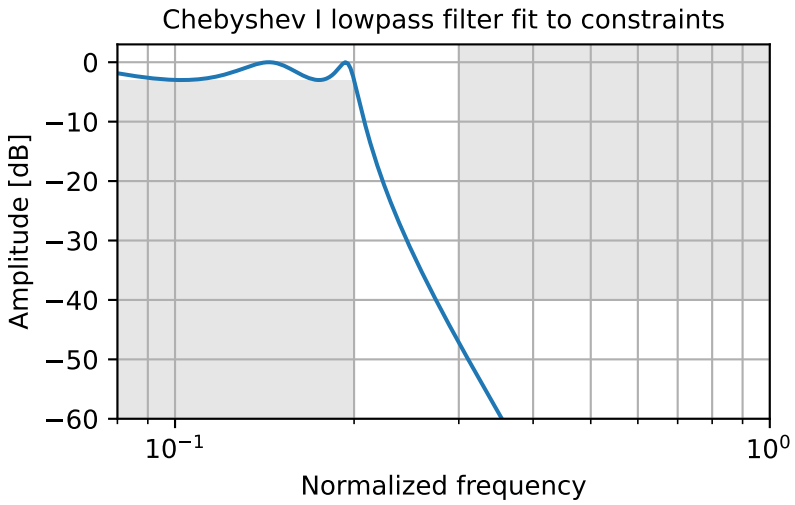
General filter design using passband and stopband spec

Examples

Design a digital lowpass filter such that the passband is within 3 dB up to 0.2*(fs/2), while rejecting at least -40 dB above 0.3*(fs/2). Plot its frequency response, showing the passband and stopband constraints in gray.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> N, Wn = signal.cheb1ord(0.2, 0.3, 3, 40)
>>> b, a = signal.cheby1(N, 3, Wn, 'low')
>>> w, h = signal.freqz(b, a)
>>> plt.semilogx(w / np.pi, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev I lowpass filter fit to constraints')
>>> plt.xlabel('Normalized frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.01, 0.2, 0.2, .01], [-3, -3, -99, -99], '0.9', lw=0) # stop
>>> plt.fill([0.3, 0.3,   2,   2], [ 9, -40, -40,  9], '0.9', lw=0) # pass
>>> plt.axis([0.08, 1, -60, 3])
>>> plt.show()
```



scipy.signal.cheby2

`scipy.signal.`**cheby2**(*N*, *rs*, *Wn*, *btype='low'*, *analog=False*, *output='ba'*, *fs=None*)

Chebyshev type II digital and analog filter design.

Design an Nth-order digital or analog Chebyshev type II filter and return the filter coefficients.

Parameters

N [int] The order of the filter.

rs [float] The minimum attenuation required in the stop band. Specified in decibels, as a positive number.

Wn [array_like] A scalar or length-2 sequence giving the critical frequencies. For Type II filters, this is the point in the transition band at which the gain first reaches *-rs*.
For digital filters, *Wn* are in the same units as *fs*. By default, *fs* is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (*Wn* is thus in half-cycles / sample.)
For analog filters, *Wn* is an angular frequency (e.g., rad/s).

btype [{'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional] The type of filter. Default is 'lowpass'.

analog [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

output [{'ba', 'zpk', 'sos'}, optional] Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba' for backwards compatibility, but 'sos' should be used for general-purpose filtering.

fs [float, optional] The sampling frequency of the digital system.
New in version 1.2.0.

Returns

b, a [ndarray, ndarray] Numerator (*b*) and denominator (*a*) polynomials of the IIR filter. Only returned if `output='ba'`.

z, p, k [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

sos [ndarray] Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

See also:

cheb2ord, **cheb2ap**

Notes

The Chebyshev type II filter maximizes the rate of cutoff between the frequency response's passband and stopband, at the expense of ripple in the stopband and increased ringing in the step response.

Type II filters do not roll off as fast as Type I (*cheby1*).

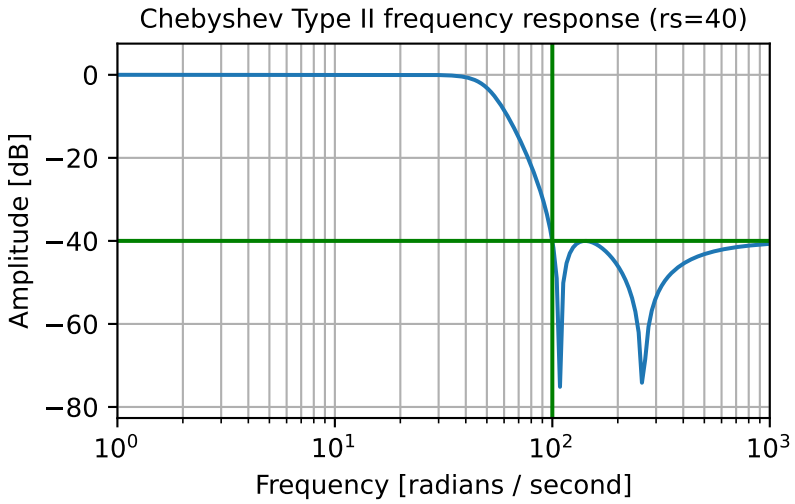
The `'sos'` output parameter was added in 0.16.0.

Examples

Design an analog filter and plot its frequency response, showing the critical points:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> b, a = signal.cheby2(4, 40, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev Type II frequency response (rs=40)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-40, color='green') # rs
>>> plt.show()
```

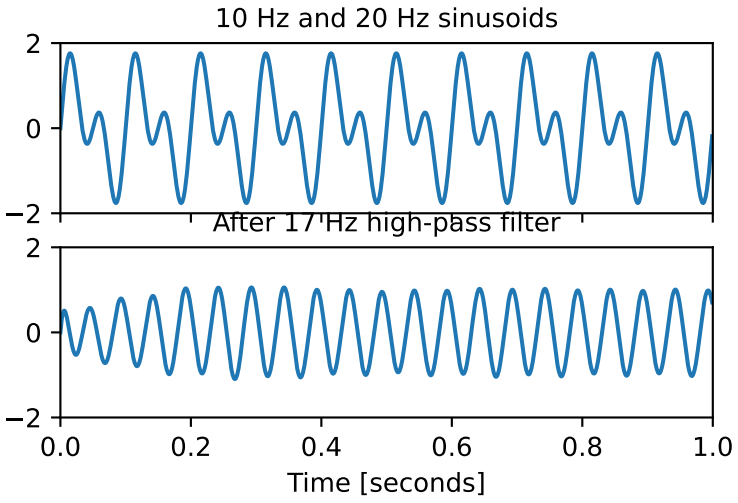


Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz

```
>>> t = np.linspace(0, 1, 1000, False)  # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
>>> ax1.set_title('10 Hz and 20 Hz sinusoids')
>>> ax1.axis([0, 1, -2, 2])
```

Design a digital high-pass filter at 17 Hz to remove the 10 Hz tone, and apply it to the signal. (It's recommended to use second-order sections format when filtering, to avoid numerical error with transfer function (`ba`) format):

```
>>> sos = signal.cheby2(12, 20, 17, 'hp', fs=1000, output='sos')
>>> filtered = signal.sosfilt(sos, sig)
>>> ax2.plot(t, filtered)
>>> ax2.set_title('After 17 Hz high-pass filter')
>>> ax2.axis([0, 1, -2, 2])
>>> ax2.set_xlabel('Time [seconds]')
>>> plt.show()
```



scipy.signal.cheb2ord

`scipy.signal.`**`cheb2ord`**(*wp*, *ws*, *gpass*, *gstop*, *analog=False*, *fs=None*)

Chebyshev type II filter order selection.

Return the order of the lowest order digital or analog Chebyshev Type II filter that loses no more than *gpass* dB in the passband and has at least *gstop* dB attenuation in the stopband.

Parameters

wp, ws [float] Passband and stopband edge frequencies.
For digital filters, these are in the same units as *fs*. By default, *fs* is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (*wp* and *ws* are thus in half-cycles / sample.) For example:

- Lowpass: wp = 0.2, ws = 0.3
- Highpass: wp = 0.3, ws = 0.2
- Bandpass: wp = [0.2, 0.5], ws = [0.1, 0.6]
- Bandstop: wp = [0.1, 0.6], ws = [0.2, 0.5]

For analog filters, *wp* and *ws* are angular frequencies (e.g., rad/s).

gpass [float] The maximum loss in the passband (dB).

gstop [float] The minimum attenuation in the stopband (dB).

analog [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

fs [float, optional] The sampling frequency of the digital system.
New in version 1.2.0.

Returns

ord [int] The lowest order for a Chebyshev type II filter that meets specs.

wn [ndarray or float] The Chebyshev natural frequency (the "3dB frequency") for use with `cheby2` to give filter results. If *fs* is specified, this is in the same units, and *fs* must also be passed to `cheby2`.

General filter design using order and critical frequencies

iirdesign

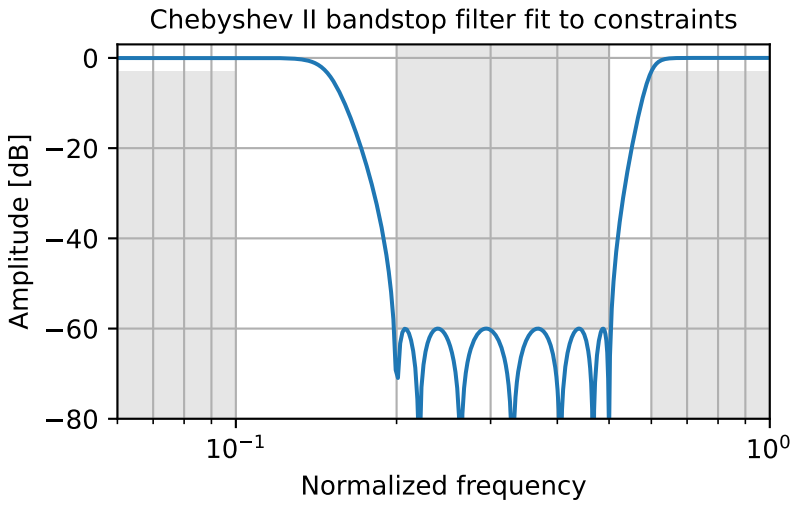
General filter design using passband and stopband spec

Examples

Design a digital bandstop filter which rejects -60 dB from 0.2*(fs/2) to 0.5*(fs/2), while staying within 3 dB below 0.1*(fs/2) or above 0.6*(fs/2). Plot its frequency response, showing the passband and stopband constraints in gray.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> N, Wn = signal.cheb2ord([0.1, 0.6], [0.2, 0.5], 3, 60)
>>> b, a = signal.cheby2(N, 60, Wn, 'stop')
>>> w, h = signal.freqz(b, a)
>>> plt.semilogx(w / np.pi, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev II bandstop filter fit to constraints')
>>> plt.xlabel('Normalized frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.01, .1, .1, .01], [-3,  -3, -99, -99], '0.9', lw=0) # stop
>>> plt.fill([.2,  .2, .5,  .5], [ 9, -60, -60,   9], '0.9', lw=0) # pass
>>> plt.fill([.6,  .6,  2,   2], [-99, -3,  -3, -99], '0.9', lw=0) # stop
>>> plt.axis([0.06, 1, -80, 3])
>>> plt.show()
```



scipy.signal.ellip

`scipy.signal.`**`ellip`**(*N*, *rp*, *rs*, *Wn*, *btype='low'*, *analog=False*, *output='ba'*, *fs=None*)

Elliptic (Cauer) digital and analog filter design.

Design an Nth-order digital or analog elliptic filter and return the filter coefficients.

Parameters

N [int] The order of the filter.

rp [float] The maximum ripple allowed below unity gain in the passband. Specified in decibels, as a positive number.

rs [float] The minimum attenuation required in the stop band. Specified in decibels, as a positive number.

Wn [array_like] A scalar or length-2 sequence giving the critical frequencies. For elliptic filters, this is the point in the transition band at which the gain first drops below *-rp*.
For digital filters, *Wn* are in the same units as *fs*. By default, *fs* is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (*Wn* is thus in half-cycles / sample.)
For analog filters, *Wn* is an angular frequency (e.g., rad/s).

btype [{'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional] The type of filter. Default is 'lowpass'.

analog [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

output [{'ba', 'zpk', 'sos'}, optional] Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba' for backwards compatibility, but 'sos' should be used for general-purpose filtering.

fs [float, optional] The sampling frequency of the digital system.
New in version 1.2.0.

Returns

b, a [ndarray, ndarray] Numerator (*b*) and denominator (*a*) polynomials of the IIR filter. Only returned if `output='ba'`.

z, p, k [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

sos [ndarray] Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

See also:

ellipord, **ellipap**

Notes

Also known as Cauer or Zolotarev filters, the elliptical filter maximizes the rate of transition between the frequency response's passband and stopband, at the expense of ripple in both, and increased ringing in the step response.

As *rp* approaches 0, the elliptical filter becomes a Chebyshev type II filter (*cheby2*). As *rs* approaches 0, it becomes a Chebyshev type I filter (*cheby1*). As both approach 0, it becomes a Butterworth filter (*butter*).

The equiripple passband has N maxima or minima (for example, a 5th-order filter has 3 maxima and 2 minima). Consequently, the DC gain is unity for odd-order filters, or -rp dB for even-order filters.

The `'sos'` output parameter was added in 0.16.0.

Examples

Design an analog filter and plot its frequency response, showing the critical points:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> b, a = signal.ellip(4, 5, 40, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Elliptic filter frequency response (rp=5, rs=40)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-40, color='green') # rs
>>> plt.axhline(-5, color='green') # rp
>>> plt.show()
```

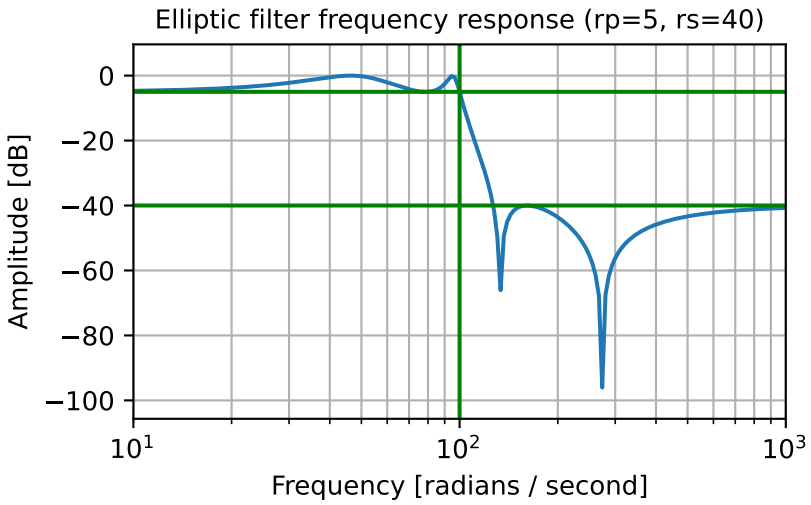
Generate a signal made up of 10 Hz and 20 Hz, sampled at 1 kHz

```
>>> t = np.linspace(0, 1, 1000, False)  # 1 second
>>> sig = np.sin(2*np.pi*10*t) + np.sin(2*np.pi*20*t)
>>> fig, (ax1, ax2) = plt.subplots(2, 1, sharex=True)
>>> ax1.plot(t, sig)
>>> ax1.set_title('10 Hz and 20 Hz sinusoids')
>>> ax1.axis([0, 1, -2, 2])
```

Design a digital high-pass filter at 17 Hz to remove the 10 Hz tone, and apply it to the signal. (It's recommended to use second-order sections format when filtering, to avoid numerical error with transfer function (`ba`) format):

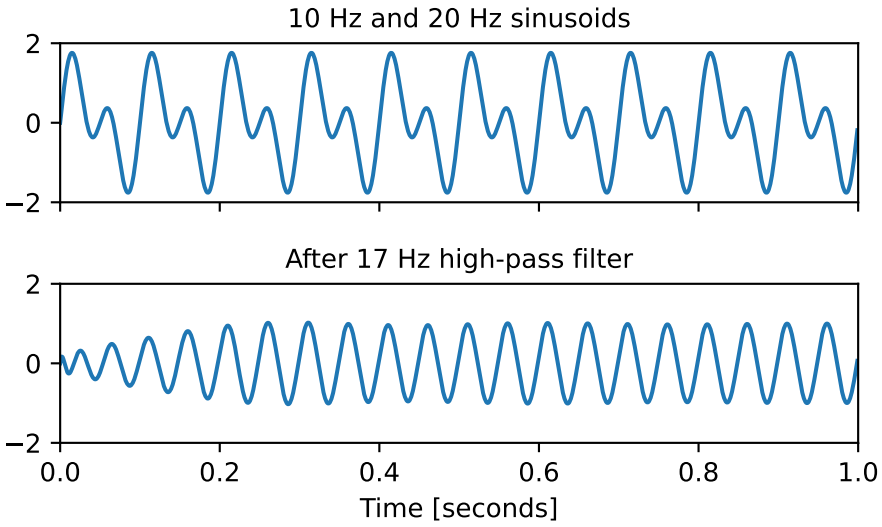
```
>>> sos = signal.ellip(8, 1, 100, 17, 'hp', fs=1000, output='sos')
>>> filtered = signal.sosfilt(sos, sig)
>>> ax2.plot(t, filtered)
>>> ax2.set_title('After 17 Hz high-pass filter')
```

(continues on next page)



(continued from previous page)

```
>>> ax2.axis([0, 1, -2, 2])
>>> ax2.set_xlabel('Time [seconds]')
>>> plt.tight_layout()
>>> plt.show()
```



scipy.signal.ellipord

scipy.signal.**ellipord**(*wp*, *ws*, *gpass*, *gstop*, *analog=False*, *fs=None*)

Elliptic (Cauer) filter order selection.

Return the order of the lowest order digital or analog elliptic filter that loses no more than *gpass* dB in the passband and has at least *gstop* dB attenuation in the stopband.

Parameters

wp, ws [float] Passband and stopband edge frequencies.
For digital filters, these are in the same units as *fs*. By default, *fs* is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (*wp* and *ws* are thus in half-cycles / sample.) For example:
- Lowpass: wp = 0.2, ws = 0.3
- Highpass: wp = 0.3, ws = 0.2
- Bandpass: wp = [0.2, 0.5], ws = [0.1, 0.6]
- Bandstop: wp = [0.1, 0.6], ws = [0.2, 0.5]

For analog filters, *wp* and *ws* are angular frequencies (e.g., rad/s).

gpass [float] The maximum loss in the passband (dB).

gstop [float] The minimum attenuation in the stopband (dB).

analog [bool, optional] When True, return an analog filter, otherwise a digital filter is returned.

fs [float, optional] The sampling frequency of the digital system.
New in version 1.2.0.

Returns

ord [int] The lowest order for an Elliptic (Cauer) filter that meets specs.

wn [ndarray or float] The Chebyshev natural frequency (the "3dB frequency") for use with *ellip* to give filter results. If *fs* is specified, this is in the same units, and *fs* must also be passed to *ellip*.

General filter design using order and critical frequencies

iirdesign

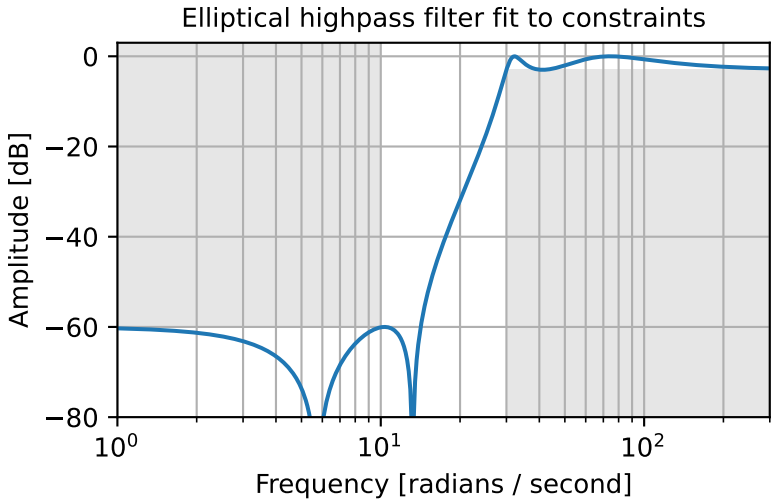
General filter design using passband and stopband spec

Examples

Design an analog highpass filter such that the passband is within 3 dB above 30 rad/s, while rejecting -60 dB at 10 rad/s. Plot its frequency response, showing the passband and stopband constraints in gray.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> N, Wn = signal.ellipord(30, 10, 3, 60, True)
>>> b, a = signal.ellip(N, 3, 60, Wn, 'high', True)
>>> w, h = signal.freqs(b, a, np.logspace(0, 3, 500))
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Elliptical highpass filter fit to constraints')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.1, 10,  10,  .1], [1e4, 1e4, -60, -60], '0.9', lw=0) # stop
>>> plt.fill([30, 30, 1e9, 1e9], [-99,  -3,  -3, -99], '0.9', lw=0) # pass
>>> plt.axis([1, 300, -80, 3])
>>> plt.show()
```



scipy.signal.bessel

`scipy.signal.`**`bessel`**(*N*, *Wn*, *btype='low'*, *analog=False*, *output='ba'*, *norm='phase'*, *fs=None*)

Bessel/Thomson digital and analog filter design.

Design an Nth-order digital or analog Bessel filter and return the filter coefficients.

Parameters

N [int] The order of the filter.

Wn [array_like] A scalar or length-2 sequence giving the critical frequencies (defined by the *norm* parameter). For analog filters, *Wn* is an angular frequency (e.g., rad/s).
For digital filters, *Wn* are in the same units as *fs*. By default, *fs* is 2 half-cycles/sample, so these are normalized from 0 to 1, where 1 is the Nyquist frequency. (*Wn* is thus in half-cycles / sample.)

btype [{'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional] The type of filter. Default is 'lowpass'.

analog [bool, optional] When True, return an analog filter, otherwise a digital filter is returned. (See Notes.)

output [{'ba', 'zpk', 'sos'}, optional] Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

norm [{'phase', 'delay', 'mag'}, optional] Critical frequency normalization:

`phase` The filter is normalized such that the phase response reaches its midpoint at angular (e.g. rad/s) frequency *Wn*. This happens for both low-pass and high-pass filters, so this is the "phase-matched" case.
The magnitude response asymptotes are the same as a Butterworth filter of the same order with a cutoff of *Wn*.
This is the default, and matches MATLAB's implementation.

`delay` The filter is normalized such that the group delay in the passband is 1/*Wn* (e.g., seconds). This is the "natural" type obtained by solving Bessel polynomials.

`mag` The filter is normalized such that the gain magnitude is -3 dB at angular frequency *Wn*.

New in version 0.18.0.

fs [float, optional] The sampling frequency of the digital system.
New in version 1.2.0.

Returns

b, a [ndarray, ndarray] Numerator (*b*) and denominator (*a*) polynomials of the IIR filter. Only returned if `output='ba'`.

z, p, k [ndarray, ndarray, float] Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

sos [ndarray] Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

Notes

Also known as a Thomson filter, the analog Bessel filter has maximally flat group delay and maximally linear phase response, with very little ringing in the step response. [1]

The Bessel is inherently an analog filter. This function generates digital Bessel filters using the bilinear transform, which does not preserve the phase response of the analog filter. As such, it is only approximately correct at frequencies below about fs/4. To get maximally-flat group delay at higher frequencies, the analog Bessel filter must be transformed using phase-preserving techniques.

See *`besselap`* for implementation details and references.

The `'sos'` output parameter was added in 0.16.0.

References

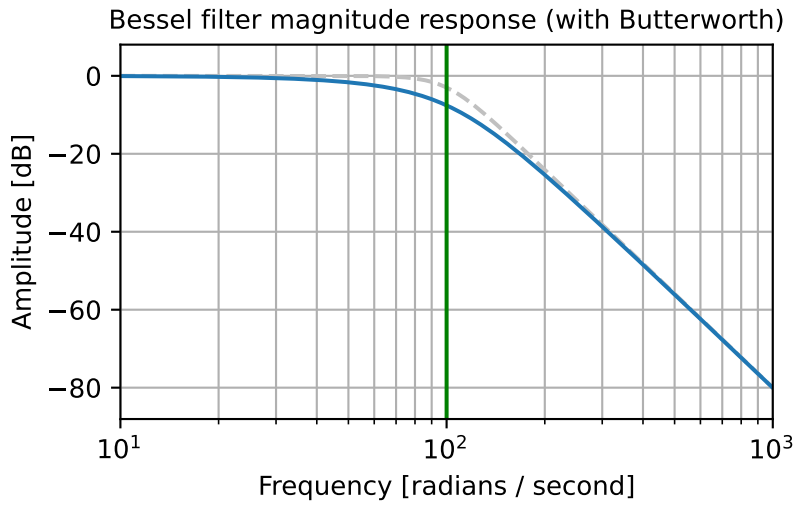
[1]

Examples

Plot the phase-normalized frequency response, showing the relationship to the Butterworth's cutoff frequency (green):

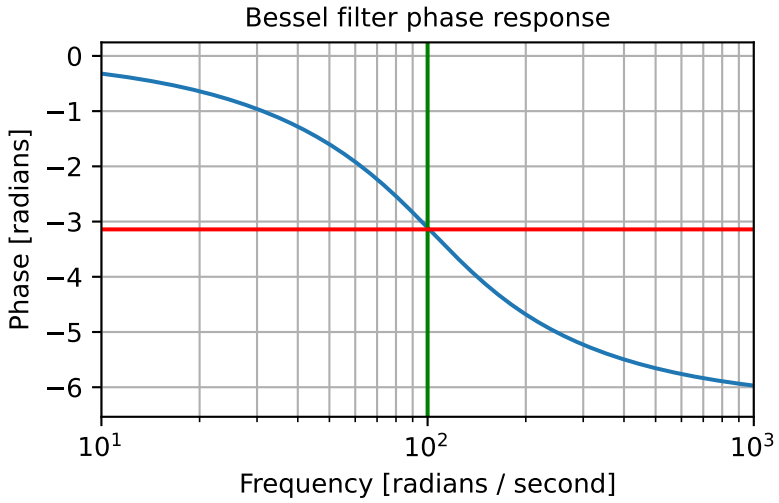
```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> b, a = signal.butter(4, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)), color='silver', ls='dashed')
>>> b, a = signal.bessel(4, 100, 'low', analog=True, norm='phase')
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)))
>>> plt.title('Bessel filter magnitude response (with Butterworth)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green')  # cutoff frequency
>>> plt.show()
```



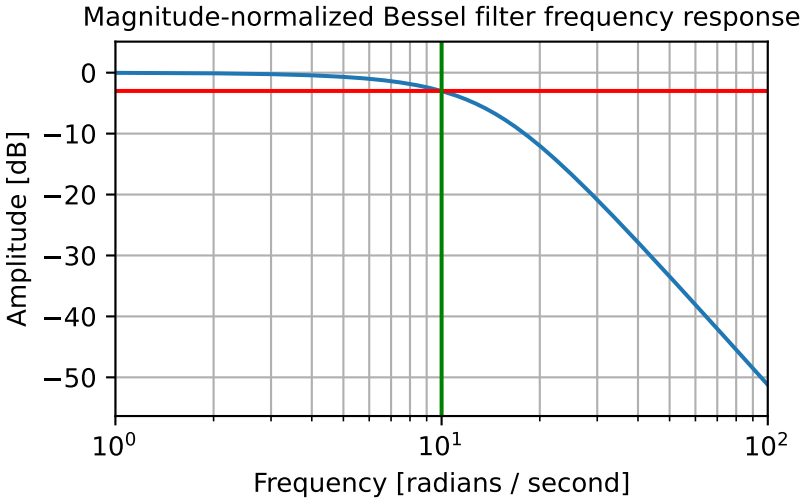
and the phase midpoint:

```
>>> plt.figure()
>>> plt.semilogx(w, np.unwrap(np.angle(h)))
>>> plt.axvline(100, color='green')  # cutoff frequency
>>> plt.axhline(-np.pi, color='red')  # phase midpoint
>>> plt.title('Bessel filter phase response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Phase [radians]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()
```



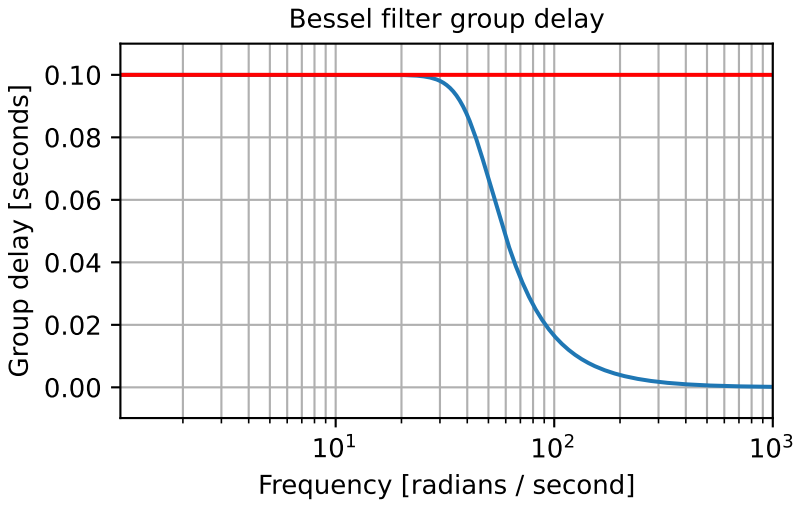
Plot the magnitude-normalized frequency response, showing the -3 dB cutoff:

```
>>> b, a = signal.bessel(3, 10, 'low', analog=True, norm='mag')
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)))
>>> plt.axhline(-3, color='red')  # -3 dB magnitude
>>> plt.axvline(10, color='green')  # cutoff frequency
>>> plt.title('Magnitude-normalized Bessel filter frequency response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()
```



Plot the delay-normalized filter, showing the maximally-flat group delay at 0.1 seconds:

```
>>> b, a = signal.bessel(5, 1/0.1, 'low', analog=True, norm='delay')
>>> w, h = signal.freqs(b, a)
>>> plt.figure()
>>> plt.semilogx(w[1:], -np.diff(np.unwrap(np.angle(h)))/np.diff(w))
>>> plt.axhline(0.1, color='red')  # 0.1 seconds group delay
>>> plt.title('Bessel filter group delay')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Group delay [seconds]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()
```



scipy.signal.iirnotch

scipy.signal.**iirnotch**(*w0*, *Q*, *fs=2.0*)

Design second-order IIR notch digital filter.

A notch filter is a band-stop filter with a narrow bandwidth (high quality factor). It rejects a narrow frequency band and leaves the rest of the spectrum little changed.

Parameters

w0 [float] Frequency to remove from a signal. If *fs* is specified, this is in the same units as *fs*. By default, it is a normalized scalar that must satisfy `0 < w0 < 1`, with `w0 = 1` corresponding to half of the sampling frequency.

Q [float] Quality factor. Dimensionless parameter that characterizes notch filter -3 dB bandwidth `bw` relative to its center frequency, `Q = w0/bw`.

fs [float, optional] The sampling frequency of the digital system.
New in version 1.2.0.

Returns

b, a [ndarray, ndarray] Numerator (`b`) and denominator (`a`) polynomials of the IIR filter.

See also:

`iirpeak`

Notes

New in version 0.19.0.

References

[1]

Examples

Design and plot filter to remove the 60 Hz component from a signal sampled at 200 Hz, using a quality factor Q = 30

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> fs = 200.0  # Sample frequency (Hz)
>>> f0 = 60.0  # Frequency to be removed from signal (Hz)
>>> Q = 30.0  # Quality factor
>>> # Design notch filter
>>> b, a = signal.iirnotch(f0, Q, fs)
```

```
>>> # Frequency response
>>> freq, h = signal.freqz(b, a, fs=fs)
>>> # Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(abs(h)), color='blue')
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 100])
>>> ax[0].set_ylim([-25, 10])
>>> ax[0].grid()
>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlabel("Frequency (Hz)")
>>> ax[1].set_xlim([0, 100])
>>> ax[1].set_yticks([-90, -60, -30, 0, 30, 60, 90])
>>> ax[1].set_ylim([-90, 90])
>>> ax[1].grid()
>>> plt.show()
```

scipy.signal.iirpeak

scipy.signal.**iirpeak**(*w0*, *Q*, *fs=2.0*)

Design second-order IIR peak (resonant) digital filter.

A peak filter is a band-pass filter with a narrow bandwidth (high quality factor). It rejects components outside a narrow frequency band.

Parameters

w0 [float] Frequency to be retained in a signal. If *fs* is specified, this is in the same units as *fs*. By default, it is a normalized scalar that must satisfy `0 < w0 < 1`, with `w0 = 1` corresponding to half of the sampling frequency.

Examples

Design and plot filter to remove the frequencies other than the 300 Hz component from a signal sampled at 1000 Hz, using a quality factor Q = 30

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

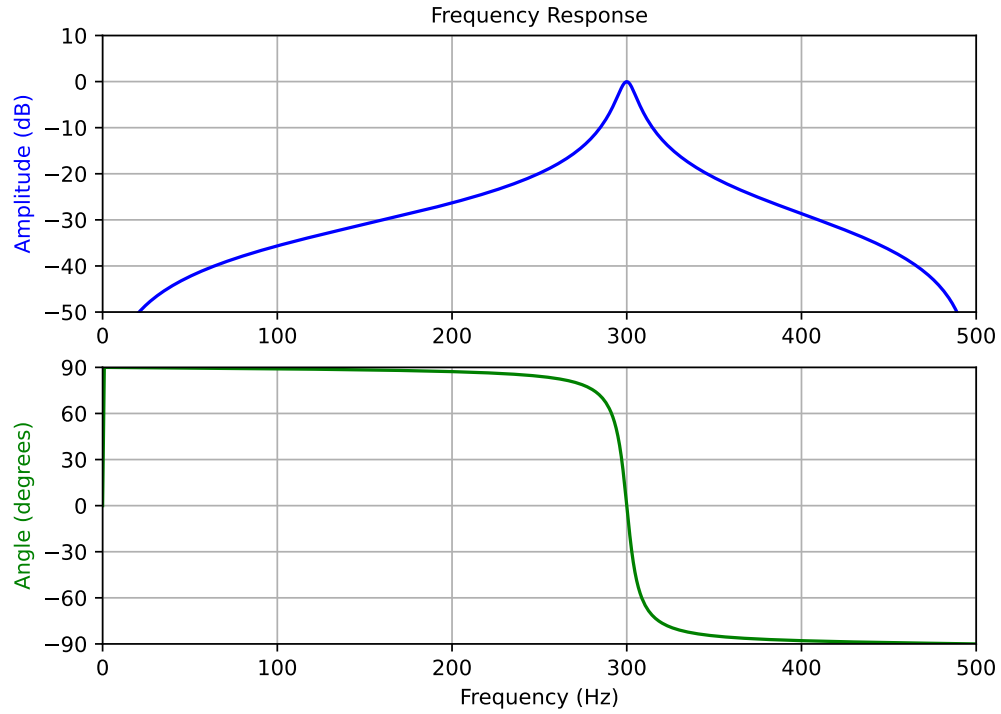
```
>>> fs = 1000.0  # Sample frequency (Hz)
>>> f0 = 300.0  # Frequency to be retained (Hz)
>>> Q = 30.0  # Quality factor
>>> # Design peak filter
>>> b, a = signal.iirpeak(f0, Q, fs)
```

```
>>> # Frequency response
>>> freq, h = signal.freqz(b, a, fs=fs)
>>> # Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(np.maximum(abs(h), 1e-5)), color='blue')
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 500])
>>> ax[0].set_ylim([-50, 10])
>>> ax[0].grid()
>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlabel("Frequency (Hz)")
>>> ax[1].set_xlim([0, 500])
>>> ax[1].set_yticks([-90, -60, -30, 0, 30, 60, 90])
>>> ax[1].set_ylim([-90, 90])
```

(continues on next page)

(continued from previous page)

```
>>> ax[1].grid()
>>> plt.show()
```



scipy.signal.iircomb

`scipy.signal.`**`iircomb`**(*w0*, *Q*, *ftype='notch'*, *fs=2.0*)

Design IIR notching or peaking digital comb filter.

A notching comb filter is a band-stop filter with a narrow bandwidth (high quality factor). It rejects a narrow frequency band and leaves the rest of the spectrum little changed.

A peaking comb filter is a band-pass filter with a narrow bandwidth (high quality factor). It rejects components outside a narrow frequency band.

Parameters

w0 [float] Frequency to attenuate (notching) or boost (peaking). If *fs* is specified, this is in the same units as *fs*. By default, it is a normalized scalar that must satisfy `0 < w0 < 1`, with `w0 = 1` corresponding to half of the sampling frequency.

Q [float] Quality factor. Dimensionless parameter that characterizes notch filter -3 dB bandwidth `bw` relative to its center frequency, `Q = w0/bw`.

ftype [{'notch', 'peak'}] The type of comb filter generated by the function. If 'notch', then it returns a filter with notches at frequencies `0`, `w0`, `2 * w0`, etc. If 'peak', then it returns a filter with peaks at frequencies `0.5 * w0`, `1.5 * w0`, `2.5 * w0`, etc. Default is 'notch'.

fs [float, optional] The sampling frequency of the signal. Default is 2.0.

Returns

b, a [ndarray, ndarray] Numerator (`b`) and denominator (`a`) polynomials of the IIR filter.

Raises

ValueError
If *w0* is less than or equal to 0 or greater than or equal to `fs/2`, if *fs* is not divisible by *w0*, if *ftype* is not 'notch' or 'peak'

See also:

iirnotch

iirpeak

Notes

For implementation details, see [1]. The TF implementation of the comb filter is numerically stable even at higher orders due to the use of a single repeated pole, which won't suffer from precision loss.

[1]

Examples

Design and plot notching comb filter at 20 Hz for a signal sampled at 200 Hz, using quality factor Q = 30

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

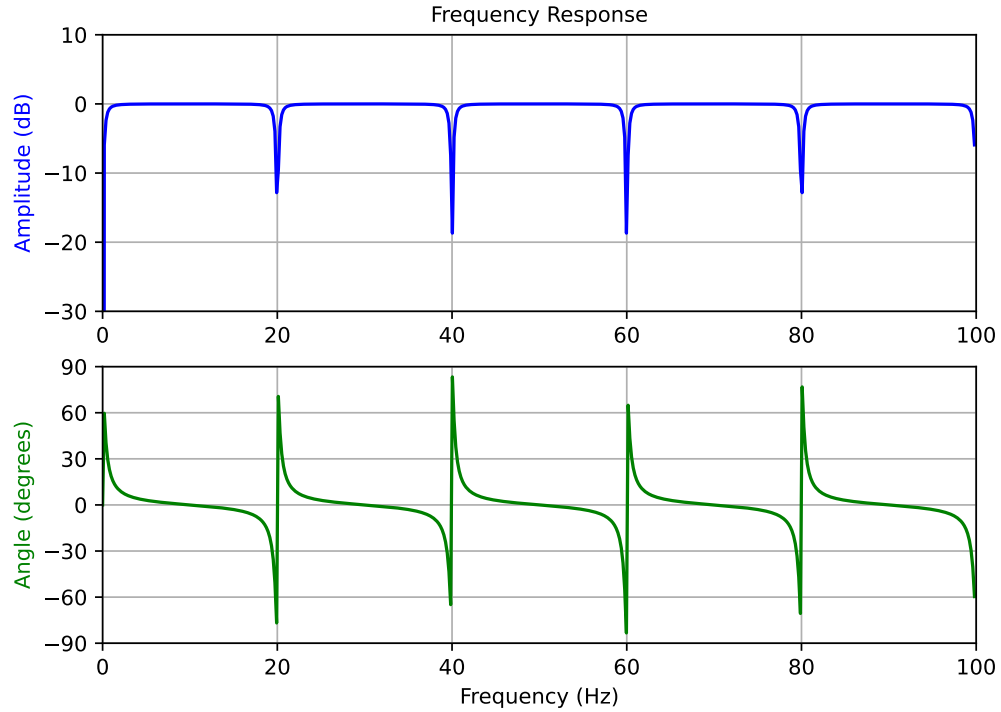
```
>>> fs = 200.0  # Sample frequency (Hz)
>>> f0 = 20.0  # Frequency to be removed from signal (Hz)
>>> Q = 30.0  # Quality factor
>>> # Design notching comb filter
>>> b, a = signal.iircomb(f0, Q, ftype='notch', fs=fs)
```

```
>>> # Frequency response
>>> freq, h = signal.freqz(b, a, fs=fs)
>>> response = abs(h)
>>> # To avoid divide by zero when graphing
>>> response[response == 0] = 1e-20
>>> # Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(abs(response)), color='blue')
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 100])
>>> ax[0].set_ylim([-30, 10])
>>> ax[0].grid()
```

(continues on next page)

(continued from previous page)

```
>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlabel("Frequency (Hz)")
>>> ax[1].set_xlim([0, 100])
>>> ax[1].set_yticks([-90, -60, -30, 0, 30, 60, 90])
>>> ax[1].set_ylim([-90, 90])
>>> ax[1].grid()
>>> plt.show()
```



Design and plot peaking comb filter at 250 Hz for a signal sampled at 1000 Hz, using quality factor Q = 30

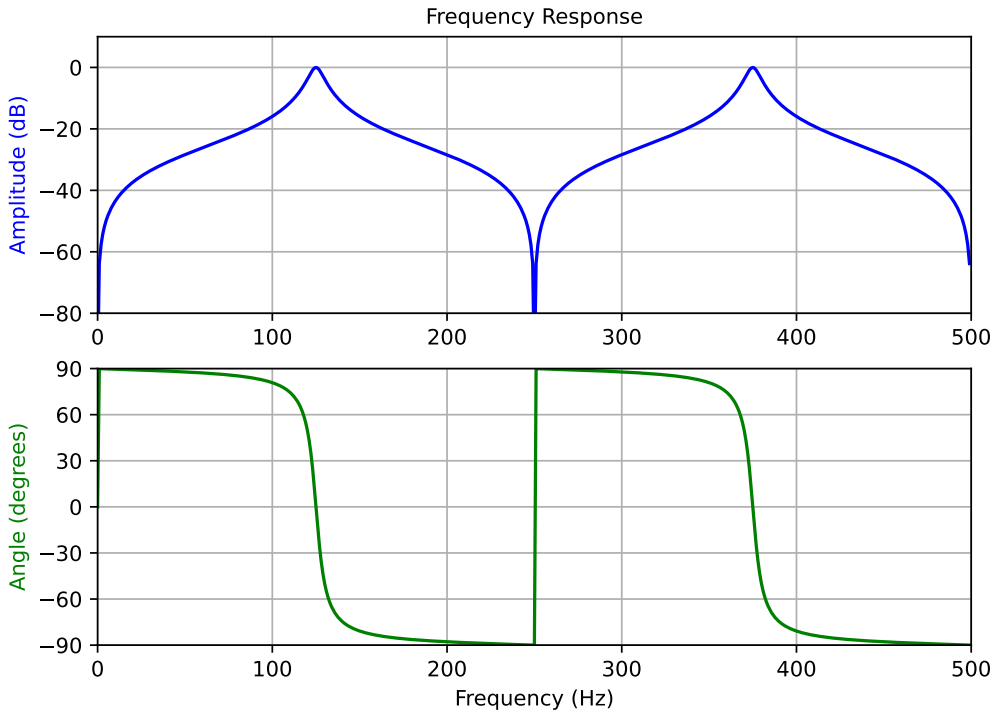
```
>>> fs = 1000.0  # Sample frequency (Hz)
>>> f0 = 250.0  # Frequency to be retained (Hz)
>>> Q = 30.0  # Quality factor
>>> # Design peaking filter
>>> b, a = signal.iircomb(f0, Q, ftype='peak', fs=fs)
```

```
>>> # Frequency response
>>> freq, h = signal.freqz(b, a, fs=fs)
>>> response = abs(h)
>>> # To avoid divide by zero when graphing
```

(continues on next page)

(continued from previous page)

```
>>> response[response == 0] = 1e-20
>>> # Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(np.maximum(abs(h), 1e-5)), color='blue')
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 500])
>>> ax[0].set_ylim([-80, 10])
>>> ax[0].grid()
>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlabel("Frequency (Hz)")
>>> ax[1].set_xlim([0, 500])
>>> ax[1].set_yticks([-90, -60, -30, 0, 30, 60, 90])
>>> ax[1].set_ylim([-90, 90])
>>> ax[1].grid()
>>> plt.show()
```



Continuous-time linear systems

lti(*system)	Continuous-time linear time invariant system base class.
StateSpace(*system, **kwargs)	Linear Time Invariant system in state-space form.
TransferFunction(*system, **kwargs)	Linear Time Invariant system class in transfer function form.
ZerosPolesGain(*system, **kwargs)	Linear Time Invariant system class in zeros, poles, gain form.
lsim(system, U, T[, X0, interp])	Simulate output of a continuous-time linear system.
lsim2(system[, U, T, X0])	Simulate output of a continuous-time linear system, by using the ODE solver *scipy.integrate.odeint*.
impulse(system[, X0, T, N])	Impulse response of continuous-time system.
impulse2(system[, X0, T, N])	Impulse response of a single-input, continuous-time linear system.
step(system[, X0, T, N])	Step response of continuous-time system.
step2(system[, X0, T, N])	Step response of continuous-time system.
freqresp(system[, w, n])	Calculate the frequency response of a continuous-time system.
bode(system[, w, n])	Calculate Bode magnitude and phase data of a continuous-time system.

scipy.signal.lti

class scipy.signal.**lti**(**system*)

Continuous-time linear time invariant system base class.

Parameters

***system** [arguments] The *lti* class can be instantiated with either 2, 3 or 4 arguments. The following gives the number of arguments and the corresponding continuous-time subclass that is created:
- 2: *TransferFunction*: (numerator, denominator)
- 3: *ZerosPolesGain*: (zeros, poles, gain)
- 4: *StateSpace*: (A, B, C, D)

Each argument can be an array or a sequence.

See also:

ZerosPolesGain, **StateSpace**, **TransferFunction**, **dlti**

Notes

lti instances do not exist directly. Instead, *lti* creates an instance of one of its subclasses: *StateSpace*, *TransferFunction* or *ZerosPolesGain*.

If (numerator, denominator) is passed in for `*system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g., `s^2 + 3s + 5` would be represented as `[1, 3, 5]`).

Changing the value of properties that are not directly part of the current system representation (such as the `zeros` of a *StateSpace* system) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

Examples

```
>>> from scipy import signal
```

```
>>> signal.lti(1, 2, 3, 4)
StateSpaceContinuous(
array([[1]]),
array([[2]]),
array([[3]]),
array([[4]]),
dt: None
)
```

Construct the transfer function $H(s) = \frac{5(s-1)(s-2)}{(s-3)(s-4)}$:

```
>>> signal.lti([1, 2], [3, 4], 5)
ZerosPolesGainContinuous(
array([1, 2]),
array([3, 4]),
5,
dt: None
)
```

Construct the transfer function $H(s) = \frac{3s+4}{1s+2}$:

```
>>> signal.lti([3, 4], [1, 2])
TransferFunctionContinuous(
array([3., 4.]),
array([1., 2.]),
dt: None
)
```

Attributes

dt	Return the sampling time of the system, *None* for `lti` systems.
poles	Poles of the system.
zeros	Zeros of the system.

Methods

`bode`([w, n])	Calculate Bode magnitude and phase data of a continuous-time system.
`freqresp`([w, n])	Calculate the frequency response of a continuous-time system.
`impulse`([X0, T, N])	Return the impulse response of a continuous-time system.
`output`(U, T[, X0])	Return the response of a continuous-time system to input *U*.
`step`([X0, T, N])	Return the step response of a continuous-time system.
`to_discrete`(dt[, method, alpha])	Return a discretized version of the current system.

scipy.signal.lti.bode

lti.**bode**(*w=None*, *n=100*)

Calculate Bode magnitude and phase data of a continuous-time system.

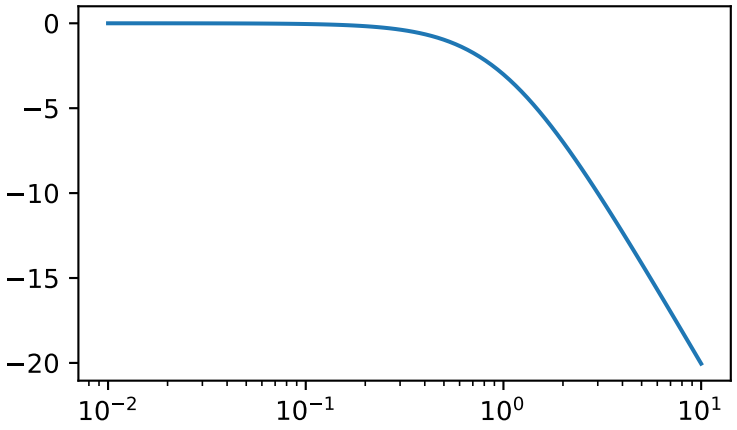
Returns a 3-tuple containing arrays of frequencies [rad/s], magnitude [dB] and phase [deg]. See *bode* for details.

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> sys = signal.TransferFunction([1], [1, 1])
>>> w, mag, phase = sys.bode()
```

```
>>> plt.figure()
>>> plt.semilogx(w, mag)    # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```

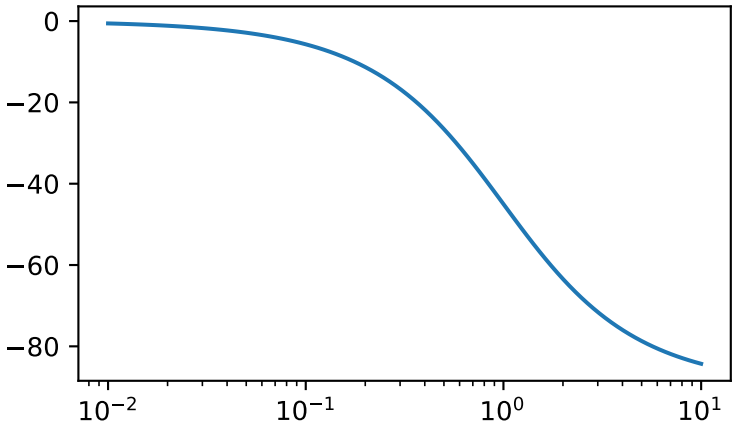


scipy.signal.lti.freqresp

lti.**freqresp**(*w=None*, *n=10000*)

Calculate the frequency response of a continuous-time system.

Returns a 2-tuple containing arrays of frequencies [rad/s] and complex magnitude. See *freqresp* for details.



scipy.signal.lti.impulse

`lti.`**`impulse`**(*X0=None*, *T=None*, *N=None*)
Return the impulse response of a continuous-time system. See *impulse* for details.

scipy.signal.lti.output

`lti.`**`output`**(*U*, *T*, *X0=None*)
Return the response of a continuous-time system to input *U*. See *lsim* for details.

scipy.signal.lti.step

`lti.`**`step`**(*X0=None*, *T=None*, *N=None*)
Return the step response of a continuous-time system. See *step* for details.

scipy.signal.lti.to_discrete

`lti.`**`to_discrete`**(*dt*, *method='zoh'*, *alpha=None*)
Return a discretized version of the current system.

Parameters: See *cont2discrete* for details.

Returns

sys: instance of *dlti*

scipy.signal.StateSpace

class scipy.signal.**StateSpace**(**system*, ***kwargs*)

Linear Time Invariant system in state-space form.

Represents the system as the continuous-time, first order differential equation $\dot{x} = Ax + Bu$ or the discrete-time difference equation $x[k+1] = Ax[k] + Bu[k]$. *StateSpace* systems inherit additional functionality from the *lti*, respectively the *dlti* classes, depending on which system representation is used.

Parameters

***system: arguments**

The *StateSpace* class can be instantiated with 1 or 4 arguments. The following gives the number of input arguments and their interpretation:

- 1: *lti* or *dlti* system: (*StateSpace*, *TransferFunction* or *ZerosPolesGain*)
- 4: array_like: (A, B, C, D)

dt: float, optional

Sampling time [s] of the discrete-time systems. Defaults to *None* (continuous-time). Must be specified as a keyword argument, for example, `dt=0.1`.

See also:

TransferFunction, **ZerosPolesGain**, **lti**, **dlti**

ss2zpk, **ss2tf**, **zpk2sos**

Notes

Changing the value of properties that are not part of the *StateSpace* system representation (such as `zeros` or `poles`) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

Examples

```
>>> from scipy import signal
```

```
>>> a = np.array([[0, 1], [0, 0]])
>>> b = np.array([[0], [1]])
>>> c = np.array([[1, 0]])
>>> d = np.array([[0]])
```

```
>>> sys = signal.StateSpace(a, b, c, d)
>>> print(sys)
StateSpaceContinuous(
array([[0, 1],
       [0, 0]]),
array([[0],
       [1]]),
array([[1, 0]]),
array([[0]]),
dt: None
)
```

```
>>> sys.to_discrete(0.1)
StateSpaceDiscrete(
array([[1. , 0.1],
       [0. , 1. ]]),
array([[0.005],
       [0.1  ]]),
array([[1, 0]]),
array([[0]]),
dt: 0.1
)
```

```
>>> a = np.array([[1, 0.1], [0, 1]])
>>> b = np.array([[0.005], [0.1]])
```

```
>>> signal.StateSpace(a, b, c, d, dt=0.1)
StateSpaceDiscrete(
array([[1. , 0.1],
       [0. , 1. ]]),
array([[0.005],
       [0.1  ]]),
array([[1, 0]]),
array([[0]]),
dt: 0.1
)
```

Attributes

A	State matrix of the *StateSpace* system.
B	Input matrix of the *StateSpace* system.
C	Output matrix of the *StateSpace* system.
D	Feedthrough matrix of the *StateSpace* system.
dt	Return the sampling time of the system, *None* for *lti* systems.
poles	Poles of the system.
zeros	Zeros of the system.

Methods

__mul__(other)	Post-multiply another system or a scalar
to_ss()	Return a copy of the current *StateSpace* system.
to_tf(**kwargs)	Convert system representation to *TransferFunction*.
to_zpk(**kwargs)	Convert system representation to *ZerosPolesGain*.

scipy.signal.StateSpace.__mul__

StateSpace.**__mul__**(*other*)
Post-multiply another system or a scalar

Handles multiplication of systems in the sense of a frequency domain multiplication. That means, given two systems E1(s) and E2(s), their multiplication, H(s) = E1(s) * E2(s), means that applying H(s) to U(s) is equivalent to first applying E2(s), and then E1(s).

Notes

For SISO systems the order of system application does not matter. However, for MIMO systems, where the two systems are matrices, the order above ensures standard Matrix multiplication rules apply.

scipy.signal.StateSpace.to_ss

StateSpace.**to_ss**()
Return a copy of the current *StateSpace* system.

Returns

sys [instance of *StateSpace*] The current system (copy)

scipy.signal.StateSpace.to_tf

StateSpace.**to_tf**(***kwargs*)
Convert system representation to *TransferFunction*.

Parameters

kwargs [dict, optional] Additional keywords passed to *ss2zpk*

Returns

sys [instance of *TransferFunction*] Transfer function of the current system

scipy.signal.StateSpace.to_zpk

StateSpace.**to_zpk**(***kwargs*)
Convert system representation to *ZerosPolesGain*.

Parameters

kwargs [dict, optional] Additional keywords passed to *ss2zpk*

Returns

sys [instance of *ZerosPolesGain*] Zeros, poles, gain representation of the current system

scipy.signal.TransferFunction

class scipy.signal.**TransferFunction**(**system*, ***kwargs*)

Linear Time Invariant system class in transfer function form.

Represents the system as the continuous-time transfer function $H(s) = \sum_{i=0}^{N} b[N-i]s^i / \sum_{j=0}^{M} a[M-j]s^j$ or the discrete-time transfer function $H(s) = \sum_{i=0}^{N} b[N-i]z^i / \sum_{j=0}^{M} a[M-j]z^j$, where b are elements of the numerator `num`, a are elements of the denominator `den`, and `N == len(b) - 1`, `M == len(a) - 1`. *TransferFunction* systems inherit additional functionality from the *lti*, respectively the *dlti* classes, depending on which system representation is used.

Parameters

***system: arguments**

The *TransferFunction* class can be instantiated with 1 or 2 arguments. The following gives the number of input arguments and their interpretation:

- 1: *lti* or *dlti* system: (*StateSpace*, *TransferFunction* or *ZerosPolesGain*)
- 2: array_like: (numerator, denominator)

dt: float, optional

Sampling time [s] of the discrete-time systems. Defaults to *None* (continuous-time). Must be specified as a keyword argument, for example, `dt=0.1`.

See also:

ZerosPolesGain, **StateSpace**, **lti**, **dlti**

tf2ss, **tf2zpk**, **tf2sos**

Notes

Changing the value of properties that are not part of the *TransferFunction* system representation (such as the *A*, *B*, *C*, *D* state-space matrices) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_ss()` before accessing/changing the A, B, C, D system matrices.

If (numerator, denominator) is passed in for `*system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. `s^2 + 3s + 5` or `z^2 + 3z + 5` would be represented as `[1, 3, 5]`)

Examples

Construct the transfer function $H(s) = \frac{s^2+3s+3}{s^2+2s+1}$:

```
>>> from scipy import signal
```

```
>>> num = [1, 3, 3]
>>> den = [1, 2, 1]
```

```
>>> signal.TransferFunction(num, den)
TransferFunctionContinuous(
array([1., 3., 3.]),
array([1., 2., 1.]),
dt: None
)
```

Construct the transfer function $H(z) = \frac{z^2+3z+3}{z^2+2z+1}$ with a sampling time of 0.1 seconds:

```
>>> signal.TransferFunction(num, den, dt=0.1)
TransferFunctionDiscrete(
array([1., 3., 3.]),
array([1., 2., 1.]),
dt: 0.1
)
```

Attributes

den	Denominator of the *TransferFunction* system.
dt	Return the sampling time of the system, *None* for *lti* systems.
num	Numerator of the *TransferFunction* system.
poles	Poles of the system.
zeros	Zeros of the system.

Methods

to_ss()	Convert system representation to *StateSpace*.
to_tf()	Return a copy of the current *TransferFunction* system.
to_zpk()	Convert system representation to *ZerosPoles-Gain*.

scipy.signal.TransferFunction.to_ss

TransferFunction.**to_ss**()
Convert system representation to *StateSpace*.

Returns

sys [instance of *StateSpace*] State space model of the current system

scipy.signal.TransferFunction.to_tf

TransferFunction.**to_tf**()
Return a copy of the current *TransferFunction* system.

Returns

sys [instance of *TransferFunction*] The current system (copy)

scipy.signal.TransferFunction.to_zpk

TransferFunction.**to_zpk**()
Convert system representation to *ZerosPolesGain*.

Returns

sys [instance of *ZerosPolesGain*] Zeros, poles, gain representation of the current system

scipy.signal.ZerosPolesGain

class scipy.signal.**ZerosPolesGain**(**system*, ***kwargs*)
Linear Time Invariant system class in zeros, poles, gain form.

Represents the system as the continuous- or discrete-time transfer function $H(s) = k \prod_i (s - z[i]) / \prod_j (s - p[j])$, where k is the `gain`, z are the `zeros` and p are the `poles`. *ZerosPolesGain* systems inherit additional functionality from the *lti*, respectively the *dlti* classes, depending on which system representation is used.

Parameters

***system** [arguments] The *ZerosPolesGain* class can be instantiated with 1 or 3 arguments. The following gives the number of input arguments and their interpretation:
- 1: *lti* or *dlti* system: (*StateSpace*, *TransferFunction* or *ZerosPolesGain*)
- 3: array_like: (zeros, poles, gain)

dt: float, optional
Sampling time [s] of the discrete-time systems. Defaults to *None* (continuous-time). Must be specified as a keyword argument, for example, `dt=0.1`.

See also:

TransferFunction, **StateSpace**, **lti**, **dlti**

zpk2ss, **zpk2tf**, **zpk2sos**

Notes

Changing the value of properties that are not part of the *ZerosPolesGain* system representation (such as the *A*, *B*, *C*, *D* state-space matrices) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_ss()` before accessing/changing the A, B, C, D system matrices.

Examples

Construct the transfer function $H(s) = \frac{5(s-1)(s-2)}{(s-3)(s-4)}$:

```
>>> from scipy import signal
```

```
>>> signal.ZerosPolesGain([1, 2], [3, 4], 5)
ZerosPolesGainContinuous(
array([1, 2]),
array([3, 4]),
5,
```

(continues on next page)

(continued from previous page)

```
dt: None
)
```

Construct the transfer function $H(z) = \frac{5(z-1)(z-2)}{(z-3)(z-4)}$ with a sampling time of 0.1 seconds:

```
>>> signal.ZerosPolesGain([1, 2], [3, 4], 5, dt=0.1)
ZerosPolesGainDiscrete(
array([1, 2]),
array([3, 4]),
5,
dt: 0.1
)
```

Attributes

dt	Return the sampling time of the system, *None* for *lti* systems.
gain	Gain of the *ZerosPolesGain* system.
poles	Poles of the *ZerosPolesGain* system.
zeros	Zeros of the *ZerosPolesGain* system.

Methods

to_ss()	Convert system representation to *StateSpace*.
to_tf()	Convert system representation to *TransferFunction*.
to_zpk()	Return a copy of the current 'ZerosPolesGain' system.

scipy.signal.ZerosPolesGain.to_ss

ZerosPolesGain.**to_ss**()
Convert system representation to *StateSpace*.

Returns

sys [instance of *StateSpace*] State space model of the current system

scipy.signal.ZerosPolesGain.to_tf

ZerosPolesGain.**to_tf**()
Convert system representation to *TransferFunction*.

Returns

sys [instance of *TransferFunction*] Transfer function of the current system

scipy.signal.ZerosPolesGain.to_zpk

ZerosPolesGain.**to_zpk**()
Return a copy of the current 'ZerosPolesGain' system.

Returns

sys [instance of *ZerosPolesGain*] The current system (copy)

scipy.signal.lsim

scipy.signal.**lsim**(*system*, *U*, *T*, *X0=None*, *interp=True*)
Simulate output of a continuous-time linear system.

Parameters

system [an instance of the LTI class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
- 1: (instance of *lti*)
- 2: (num, den)
- 3: (zeros, poles, gain)
- 4: (A, B, C, D)

U [array_like] An input array describing the input at each time *T* (interpolation is assumed between given times). If there are multiple inputs, then each column of the rank-2 array represents an input. If U = 0 or None, a zero input is used.

T [array_like] The time steps at which the input is defined and at which the output is desired. Must be nonnegative, increasing, and equally spaced.

X0 [array_like, optional] The initial conditions on the state vector (zero by default).

interp [bool, optional] Whether to use linear (True, the default) or zero-order-hold (False) interpolation for the input array.

Returns

T [1D ndarray] Time values for the output.

yout [1D ndarray] System response.

xout [ndarray] Time evolution of the state vector.

Notes

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. `s^2 + 3s + 5` would be represented as `[1, 3, 5]`).

Examples

We'll use *lsim* to simulate an analog Bessel filter applied to a signal.

```
>>> from scipy.signal import bessel, lsim
>>> import matplotlib.pyplot as plt
```

Create a low-pass Bessel filter with a cutoff of 12 Hz.

```
>>> b, a = bessel(N=5, Wn=2*np.pi*12, btype='lowpass', analog=True)
```

Generate data to which the filter is applied.

```
>>> t = np.linspace(0, 1.25, 500, endpoint=False)
```

The input signal is the sum of three sinusoidal curves, with frequencies 4 Hz, 40 Hz, and 80 Hz. The filter should mostly eliminate the 40 Hz and 80 Hz components, leaving just the 4 Hz signal.

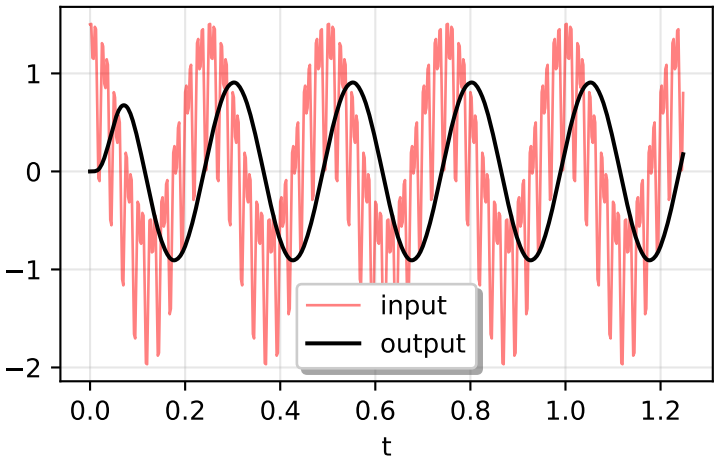
```
>>> u = (np.cos(2*np.pi*4*t) + 0.6*np.sin(2*np.pi*40*t) +
...      0.5*np.cos(2*np.pi*80*t))
```

Simulate the filter with *lsim*.

```
>>> tout, yout, xout = lsim((b, a), U=u, T=t)
```

Plot the result.

```
>>> plt.plot(t, u, 'r', alpha=0.5, linewidth=1, label='input')
>>> plt.plot(tout, yout, 'k', linewidth=1.5, label='output')
>>> plt.legend(loc='best', shadow=True, framealpha=1)
>>> plt.grid(alpha=0.3)
>>> plt.xlabel('t')
>>> plt.show()
```



In a second example, we simulate a double integrator `y'' = u`, with a constant input `u = 1`. We'll use the state space representation of the integrator.

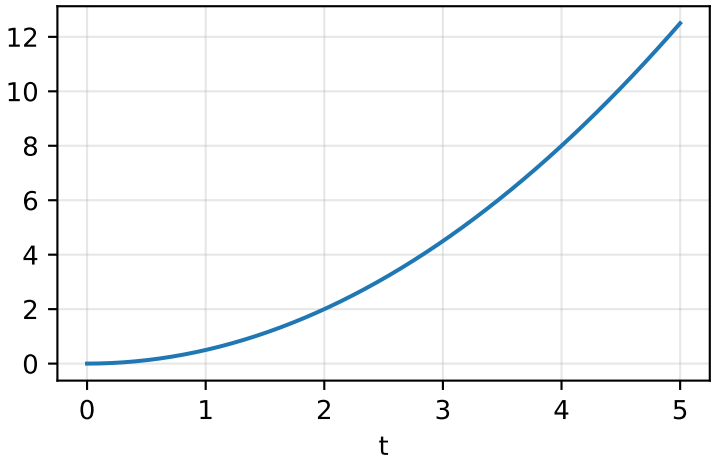
```
>>> from scipy.signal import lti
>>> A = np.array([[0.0, 1.0], [0.0, 0.0]])
>>> B = np.array([[0.0], [1.0]])
>>> C = np.array([[1.0, 0.0]])
>>> D = 0.0
>>> system = lti(A, B, C, D)
```

t and *u* define the time and input signal for the system to be simulated.

```
>>> t = np.linspace(0, 5, num=50)
>>> u = np.ones_like(t)
```

Compute the simulation, and then plot *y*. As expected, the plot shows the curve `y = 0.5*t**2`.

```
>>> tout, y, x = lsim(system, u, t)
>>> plt.plot(t, y)
>>> plt.grid(alpha=0.3)
>>> plt.xlabel('t')
>>> plt.show()
```



scipy.signal.lsim2

`scipy.signal.`**`lsim2`**(*system*, *U=None*, *T=None*, *X0=None*, ***kwargs*)

Simulate output of a continuous-time linear system, by using the ODE solver *scipy.integrate.odeint*.

Parameters

system [an instance of the *lti* class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
- 1: (instance of *lti*)
- 2: (num, den)
- 3: (zeros, poles, gain)
- 4: (A, B, C, D)

U [array_like (1D or 2D), optional] An input array describing the input at each time T. Linear interpolation is used between given times. If there are multiple inputs, then each column of the rank-2 array represents an input. If U is not given, the input is assumed to be zero.

T [array_like (1D or 2D), optional] The time steps at which the input is defined and at which the output is desired. The default is 101 evenly spaced points on the interval [0,10.0].

X0 [array_like (1D), optional] The initial condition of the state vector. If *X0* is not given, the initial conditions are assumed to be 0.

kwargs [dict] Additional keyword arguments are passed on to the function *odeint*. See the notes below for more details.

Returns

T [1D ndarray] The time values for the output.

yout [ndarray] The response of the system.

xout [ndarray] The time-evolution of the state-vector.

See also:

`lsim`

Notes

This function uses *scipy.integrate.odeint* to solve the system's differential equations. Additional keyword arguments given to *lsim2* are passed on to *odeint*. See the documentation for *scipy.integrate.odeint* for the full list of arguments.

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. `s^2 + 3s + 5` would be represented as `[1, 3, 5]`).

Examples

We'll use *lsim2* to simulate an analog Bessel filter applied to a signal.

```
>>> from scipy.signal import bessel, lsim2
>>> import matplotlib.pyplot as plt
```

Create a low-pass Bessel filter with a cutoff of 12 Hz.

```
>>> b, a = bessel(N=5, Wn=2*np.pi*12, btype='lowpass', analog=True)
```

Generate data to which the filter is applied.

```
>>> t = np.linspace(0, 1.25, 500, endpoint=False)
```

The input signal is the sum of three sinusoidal curves, with frequencies 4 Hz, 40 Hz, and 80 Hz. The filter should mostly eliminate the 40 Hz and 80 Hz components, leaving just the 4 Hz signal.

```
>>> u = (np.cos(2*np.pi*4*t) + 0.6*np.sin(2*np.pi*40*t) +
...      0.5*np.cos(2*np.pi*80*t))
```

Simulate the filter with *lsim2*.

```
>>> tout, yout, xout = lsim2((b, a), U=u, T=t)
```

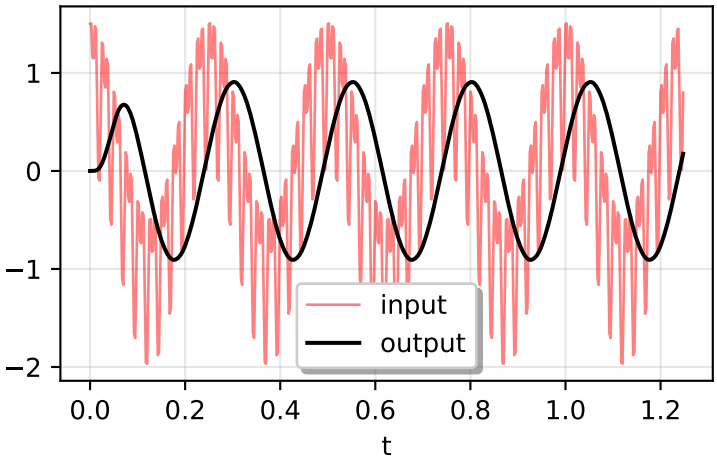
Plot the result.

```
>>> plt.plot(t, u, 'r', alpha=0.5, linewidth=1, label='input')
>>> plt.plot(tout, yout, 'k', linewidth=1.5, label='output')
>>> plt.legend(loc='best', shadow=True, framealpha=1)
>>> plt.grid(alpha=0.3)
>>> plt.xlabel('t')
>>> plt.show()
```

In a second example, we simulate a double integrator `y'' = u`, with a constant input `u = 1`. We'll use the state space representation of the integrator.

```
>>> from scipy.signal import lti
>>> A = np.array([[0, 1], [0, 0]])
>>> B = np.array([[0], [1]])
```

(continues on next page)



(continued from previous page)

```
>>> C = np.array([[1, 0]])
>>> D = 0
>>> system = lti(A, B, C, D)
```

t and *u* define the time and input signal for the system to be simulated.

```
>>> t = np.linspace(0, 5, num=50)
>>> u = np.ones_like(t)
```

Compute the simulation, and then plot *y*. As expected, the plot shows the curve `y = 0.5*t**2`.

```
>>> tout, y, x = lsim2(system, u, t)
>>> plt.plot(t, y)
>>> plt.grid(alpha=0.3)
>>> plt.xlabel('t')
>>> plt.show()
```

scipy.signal.impulse

`scipy.signal.`**`impulse`**(*system*, *X0=None*, *T=None*, *N=None*)

Impulse response of continuous-time system.

Parameters

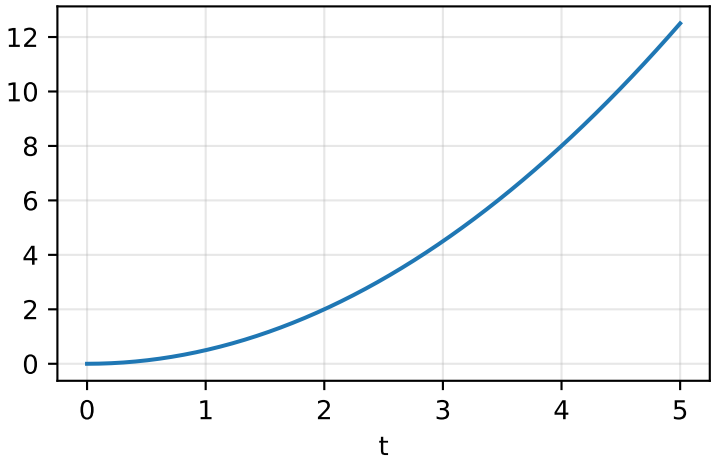
system [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
- 1 (instance of *lti*)
- 2 (num, den)
- 3 (zeros, poles, gain)
- 4 (A, B, C, D)

X0 [array_like, optional] Initial state-vector. Defaults to zero.

T [array_like, optional] Time points. Computed if not given.

N [int, optional] The number of time points to compute (if *T* is not given).

Returns



T [ndarray] A 1-D array of time points.
yout [ndarray] A 1-D array containing the impulse response of the system (except for singularities at zero).

Notes

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. `s^2 + 3s + 5` would be represented as `[1, 3, 5]`).

Examples

Compute the impulse response of a second order system with a repeated root: `x''(t) + 2*x'(t) + x(t) = u(t)`

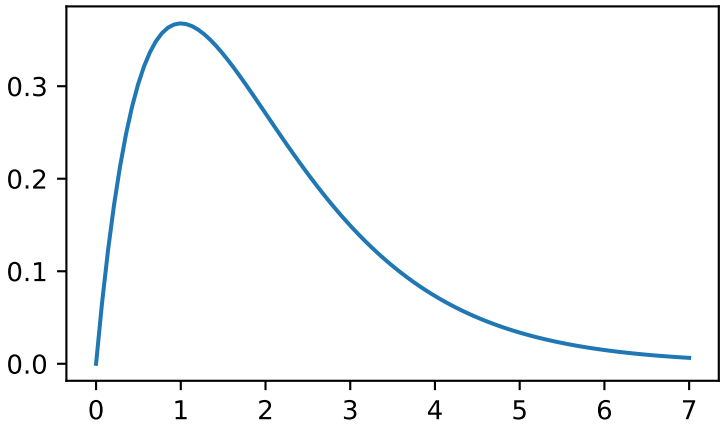
```
>>> from scipy import signal
>>> system = ([1.0], [1.0, 2.0, 1.0])
>>> t, y = signal.impulse(system)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, y)
```

scipy.signal.impulse2

`scipy.signal.`**`impulse2`**(*system*, *X0=None*, *T=None*, *N=None*, ***kwargs*)
Impulse response of a single-input, continuous-time linear system.

Parameters

system [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
- 1 (instance of *lti*)
- 2 (num, den)
- 3 (zeros, poles, gain)
- 4 (A, B, C, D)



X0	[1-D array_like, optional] The initial condition of the state vector. Default: 0 (the zero vector).
T	[1-D array_like, optional] The time steps at which the input is defined and at which the output is desired. If *T* is not given, the function will generate a set of time samples automatically.
N	[int, optional] Number of time points to compute. Default: 100.
kwargs	[various types] Additional keyword arguments are passed on to the function *scipy.signal.lsim2*, which in turn passes them on to *scipy.integrate.odeint*; see the latter's documentation for information about these arguments.

Returns

T	[ndarray] The time values for the output.
yout	[ndarray] The output response of the system.

See also:

impulse, **lsim2**, **scipy.integrate.odeint**

Notes

The solution is generated by calling *scipy.signal.lsim2*, which uses the differential equation solver *scipy.integrate.odeint*.

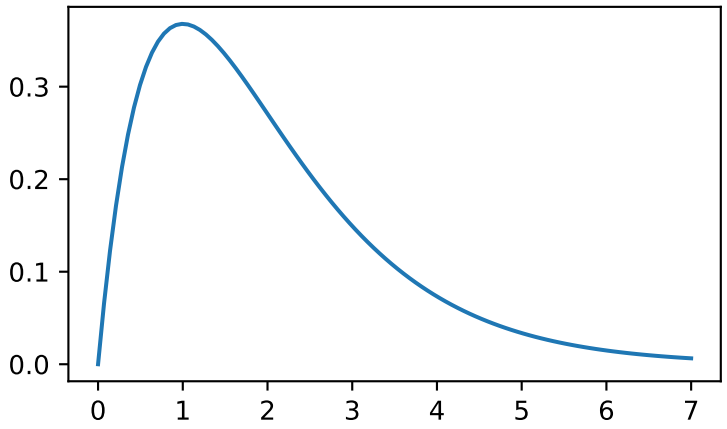
If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. `s^2 + 3s + 5` would be represented as `[1, 3, 5]`).

New in version 0.8.0.

Examples

Compute the impulse response of a second order system with a repeated root: `x''(t) + 2*x'(t) + x(t) = u(t)`

```
>>> from scipy import signal
>>> system = ([1.0], [1.0, 2.0, 1.0])
>>> t, y = signal.impulse2(system)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, y)
```



scipy.signal.step

`scipy.signal.`**`step`**(*system*, *X0=None*, *T=None*, *N=None*)

Step response of continuous-time system.

Parameters

system [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
- 1 (instance of *lti*)
- 2 (num, den)
- 3 (zeros, poles, gain)
- 4 (A, B, C, D)

X0 [array_like, optional] Initial state-vector (default is zero).

T [array_like, optional] Time points (computed if not given).

N [int, optional] Number of time points to compute if *T* is not given.

Returns

T [1D ndarray] Output time points.

yout [1D ndarray] Step response of system.

See also:

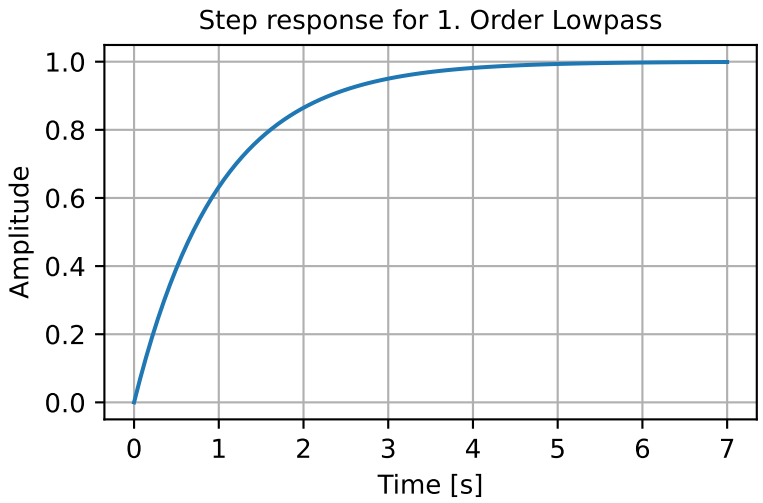
scipy.signal.step2

Notes

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. `s^2 + 3s + 5` would be represented as `[1, 3, 5]`).

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> lti = signal.lti([1.0], [1.0, 1.0])
>>> t, y = signal.step(lti)
>>> plt.plot(t, y)
>>> plt.xlabel('Time [s]')
>>> plt.ylabel('Amplitude')
>>> plt.title('Step response for 1. Order Lowpass')
>>> plt.grid()
```



scipy.signal.step2

`scipy.signal.`**`step2`**(*system*, *X0=None*, *T=None*, *N=None*, ***kwargs*)

Step response of continuous-time system.

This function is functionally the same as *`scipy.signal.step`*, but it uses the function *`scipy.signal.lsim2`* to compute the step response.

Parameters

system [an instance of the LTI class or a tuple of array_like] describing the system. The following gives the number of elements in the tuple and the interpretation:
- 1 (instance of *`lti`*)
- 2 (num, den)
- 3 (zeros, poles, gain)
- 4 (A, B, C, D)

X0 [array_like, optional] Initial state-vector (default is zero).

T [array_like, optional] Time points (computed if not given).

N [int, optional] Number of time points to compute if *T* is not given.
kwargs [various types] Additional keyword arguments are passed on the function *scipy.signal.lsim2*, which in turn passes them on to *scipy.integrate.odeint*. See the documentation for *scipy.integrate.odeint* for information about these arguments.

Returns

T [1D ndarray] Output time points.
yout [1D ndarray] Step response of system.

See also:

scipy.signal.step

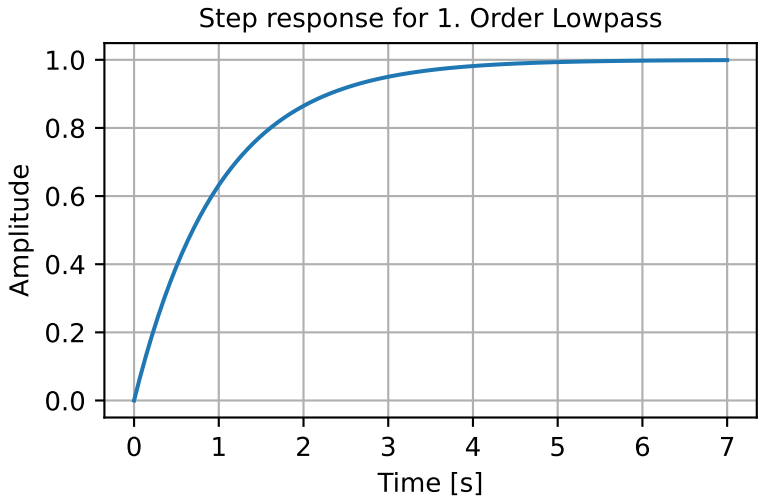
Notes

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. `s^2 + 3s + 5` would be represented as `[1, 3, 5]`).

New in version 0.8.0.

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> lti = signal.lti([1.0], [1.0, 1.0])
>>> t, y = signal.step2(lti)
>>> plt.plot(t, y)
>>> plt.xlabel('Time [s]')
>>> plt.ylabel('Amplitude')
>>> plt.title('Step response for 1. Order Lowpass')
>>> plt.grid()
```



scipy.signal.freqresp

scipy.signal.**freqresp**(*system*, *w=None*, *n=10000*)

Calculate the frequency response of a continuous-time system.

Parameters

system [an instance of the `lti` class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
- 1 (instance of `lti`)
- 2 (num, den)
- 3 (zeros, poles, gain)
- 4 (A, B, C, D)

w [array_like, optional] Array of frequencies (in rad/s). Magnitude and phase data is calculated for every value in this array. If not given, a reasonable set will be calculated.

n [int, optional] Number of frequency points to compute if *w* is not given. The *n* frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

Returns

w [1D ndarray] Frequency array [rad/s]

H [1D ndarray] Array of complex magnitude values

Notes

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. `s^2 + 3s + 5` would be represented as `[1, 3, 5]`).

Examples

Generating the Nyquist plot of a transfer function

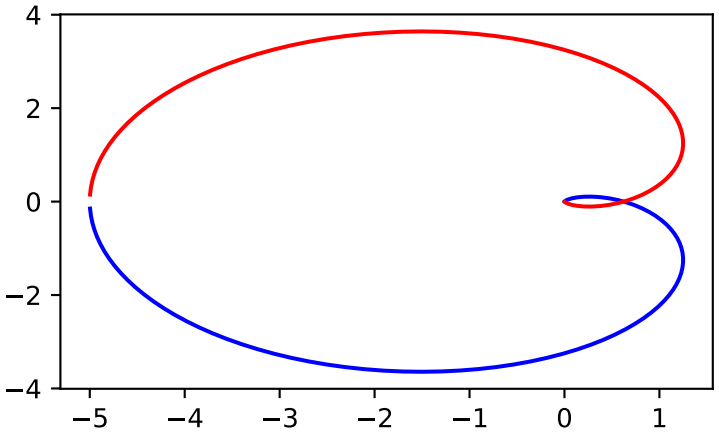
```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Construct the transfer function $H(s) = \frac{5}{(s-1)^3}$:

```
>>> s1 = signal.ZerosPolesGain([], [1, 1, 1], [5])
```

```
>>> w, H = signal.freqresp(s1)
```

```
>>> plt.figure()
>>> plt.plot(H.real, H.imag, "b")
>>> plt.plot(H.real, -H.imag, "r")
>>> plt.show()
```



scipy.signal.bode

`scipy.signal.`**bode**(*system*, *w=None*, *n=100*)

Calculate Bode magnitude and phase data of a continuous-time system.

Parameters

system [an instance of the LTI class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
- 1 (instance of `lti`)
- 2 (num, den)
- 3 (zeros, poles, gain)
- 4 (A, B, C, D)

w [array_like, optional] Array of frequencies (in rad/s). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

n [int, optional] Number of frequency points to compute if *w* is not given. The *n* frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

Returns

w [1D ndarray] Frequency array [rad/s]

mag [1D ndarray] Magnitude array [dB]

phase [1D ndarray] Phase array [deg]

Notes

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. `s^2 + 3s + 5` would be represented as `[1, 3, 5]`).

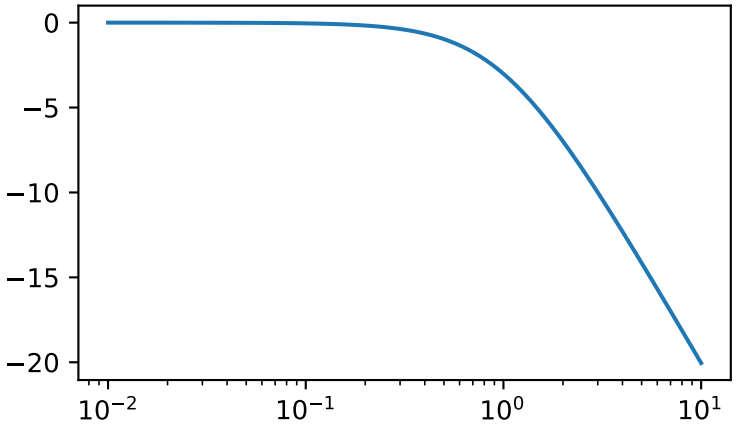
New in version 0.11.0.

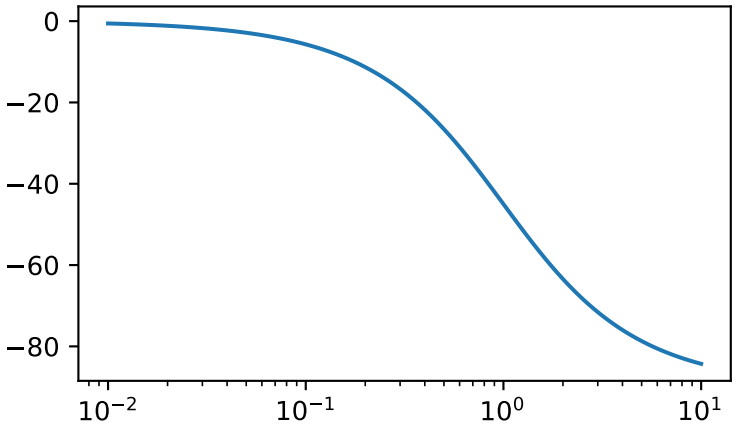
Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> sys = signal.TransferFunction([1], [1, 1])
>>> w, mag, phase = signal.bode(sys)
```

```
>>> plt.figure()
>>> plt.semilogx(w, mag)    # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```





Discrete-time linear systems

dlti(*system, **kwargs)	Discrete-time linear time invariant system base class.
StateSpace(*system, **kwargs)	Linear Time Invariant system in state-space form.
TransferFunction(*system, **kwargs)	Linear Time Invariant system class in transfer function form.
ZerosPolesGain(*system, **kwargs)	Linear Time Invariant system class in zeros, poles, gain form.
dlsim(system, u[, t, x0])	Simulate output of a discrete-time linear system.
dimpulse(system[, x0, t, n])	Impulse response of discrete-time system.
dstep(system[, x0, t, n])	Step response of discrete-time system.
dfreqresp(system[, w, n, whole])	Calculate the frequency response of a discrete-time system.
dbode(system[, w, n])	Calculate Bode magnitude and phase data of a discrete-time system.

scipy.signal.dlti

class scipy.signal.**dlti**(**system*, ***kwargs*)

Discrete-time linear time invariant system base class.

Parameters

***system: arguments**

The *dlti* class can be instantiated with either 2, 3 or 4 arguments. The following gives the number of arguments and the corresponding discrete-time subclass that is created:

- 2: *TransferFunction*: (numerator, denominator)
- 3: *ZerosPolesGain*: (zeros, poles, gain)
- 4: *StateSpace*: (A, B, C, D)

Each argument can be an array or a sequence.

dt: float, optional

Sampling time [s] of the discrete-time systems. Defaults to `True` (unspecified sampling time). Must be specified as a keyword argument, for example, `dt=0.1`.

See also:

ZerosPolesGain, **StateSpace**, **TransferFunction**, **lti**

Notes

dlti instances do not exist directly. Instead, *dlti* creates an instance of one of its subclasses: *StateSpace*, *TransferFunction* or *ZerosPolesGain*.

Changing the value of properties that are not directly part of the current system representation (such as the `zeros` of a *StateSpace* system) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

If (numerator, denominator) is passed in for `*system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g., `z^2 + 3z + 5` would be represented as `[1, 3, 5]`).

New in version 0.18.0.

Examples

```
>>> from scipy import signal
```

```
>>> signal.dlti(1, 2, 3, 4)
StateSpaceDiscrete(
array([[1]]),
array([[2]]),
array([[3]]),
array([[4]]),
dt: True
)
```

```
>>> signal.dlti(1, 2, 3, 4, dt=0.1)
StateSpaceDiscrete(
array([[1]]),
array([[2]]),
array([[3]]),
array([[4]]),
dt: 0.1
)
```

Construct the transfer function $H(z) = \frac{5(z-1)(z-2)}{(z-3)(z-4)}$ with a sampling time of 0.1 seconds:

```
>>> signal.dlti([1, 2], [3, 4], 5, dt=0.1)
ZerosPolesGainDiscrete(
array([1, 2]),
array([3, 4]),
5,
dt: 0.1
)
```

Construct the transfer function $H(z) = \frac{3z+4}{1z+2}$ with a sampling time of 0.1 seconds:

```
>>> signal.dlti([3, 4], [1, 2], dt=0.1)
TransferFunctionDiscrete(
array([3., 4.]),
array([1., 2.]),
dt: 0.1
)
```

Attributes

dt	Return the sampling time of the system.
poles	Poles of the system.
zeros	Zeros of the system.

Methods

bode([w, n])	Calculate Bode magnitude and phase data of a discrete-time system.
freqresp([w, n, whole])	Calculate the frequency response of a discrete-time system.
impulse([x0, t, n])	Return the impulse response of the discrete-time *dlti* system.
output(u, t[, x0])	Return the response of the discrete-time system to input *u*.
step([x0, t, n])	Return the step response of the discrete-time *dlti* system.

scipy.signal.dlti.bode

dlti.**bode**(*w=None*, *n=100*)

Calculate Bode magnitude and phase data of a discrete-time system.

Returns a 3-tuple containing arrays of frequencies [rad/s], magnitude [dB] and phase [deg]. See *dbode* for details.

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Construct the transfer function $H(z) = \frac{1}{z^2+2z+3}$ with sampling time 0.5s:

```
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.5)
```

Equivalent: signal.dbode(sys)

```
>>> w, mag, phase = sys.bode()
```

```
>>> plt.figure()
>>> plt.semilogx(w, mag)    # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```

scipy.signal.dlti.freqresp

dlti.**freqresp**(*w=None*, *n=10000*, *whole=False*)

Calculate the frequency response of a discrete-time system.

Returns a 2-tuple containing arrays of frequencies [rad/s] and complex magnitude. See *dfreqresp* for details.

scipy.signal.dlti.impulse

dlti.**impulse**(*x0=None*, *t=None*, *n=None*)
Return the impulse response of the discrete-time *dlti* system. See *dimpulse* for details.

scipy.signal.dlti.output

dlti.**output**(*u*, *t*, *x0=None*)
Return the response of the discrete-time system to input *u*. See *dlsim* for details.

scipy.signal.dlti.step

dlti.**step**(*x0=None*, *t=None*, *n=None*)
Return the step response of the discrete-time *dlti* system. See *dstep* for details.

scipy.signal.dlsim

scipy.signal.**dlsim**(*system*, *u*, *t=None*, *x0=None*)
Simulate output of a discrete-time linear system.

Parameters

system [tuple of array_like or instance of *dlti*] A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:
- 1: (instance of *dlti*)
- 3: (num, den, dt)
- 4: (zeros, poles, gain, dt)
- 5: (A, B, C, D, dt)

u [array_like] An input array describing the input at each time *t* (interpolation is assumed between given times). If there are multiple inputs, then each column of the rank-2 array represents an input.

t [array_like, optional] The time steps at which the input is defined. If *t* is given, it must be the same length as *u*, and the final value in *t* determines the number of steps returned in the output.

x0 [array_like, optional] The initial conditions on the state vector (zero by default).

Returns

tout [ndarray] Time values for the output, as a 1-D array.

yout [ndarray] System response, as a 1-D array.

xout [ndarray, optional] Time-evolution of the state-vector. Only generated if the input is a *StateSpace* system.

See also:

lsim, **dstep**, **dimpulse**, **cont2discrete**

Examples

A simple integrator transfer function with a discrete time step of 1.0 could be implemented as:

```
>>> from scipy import signal
>>> tf = ([1.0,], [1.0, -1.0], 1.0)
>>> t_in = [0.0, 1.0, 2.0, 3.0]
>>> u = np.asarray([0.0, 0.0, 1.0, 1.0])
>>> t_out, y = signal.dlsim(tf, u, t=t_in)
>>> y.T
array([[ 0.,  0.,  0.,  1.]])
```

scipy.signal.dimpulse

scipy.signal.**dimpulse**(*system*, *x0=None*, *t=None*, *n=None*)

Impulse response of discrete-time system.

Parameters

system [tuple of array_like or instance of *dlti*] A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:
- 1: (instance of *dlti*)
- 3: (num, den, dt)
- 4: (zeros, poles, gain, dt)
- 5: (A, B, C, D, dt)

x0 [array_like, optional] Initial state-vector. Defaults to zero.

t [array_like, optional] Time points. Computed if not given.

n [int, optional] The number of time points to compute (if *t* is not given).

Returns

tout [ndarray] Time values for the output, as a 1-D array.

yout [tuple of ndarray] Impulse response of system. Each element of the tuple represents the output of the system based on an impulse in each input.

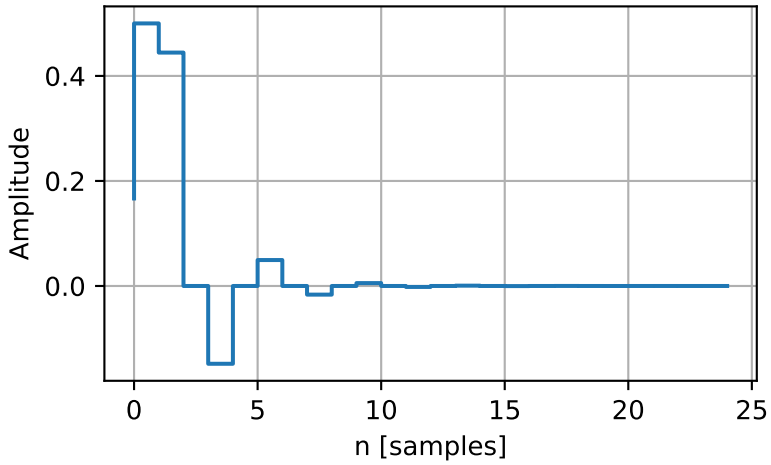
See also:

impulse, **dstep**, **dlsim**, **cont2discrete**

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> butter = signal.dlti(*signal.butter(3, 0.5))
>>> t, y = signal.dimpulse(butter, n=25)
>>> plt.step(t, np.squeeze(y))
>>> plt.grid()
>>> plt.xlabel('n [samples]')
>>> plt.ylabel('Amplitude')
```



scipy.signal.dstep

scipy.signal.**dstep**(*system*, *x0=None*, *t=None*, *n=None*)

Step response of discrete-time system.

Parameters

system [tuple of array_like] A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:
- 1: (instance of *dlti*)
- 3: (num, den, dt)
- 4: (zeros, poles, gain, dt)
- 5: (A, B, C, D, dt)

x0 [array_like, optional] Initial state-vector. Defaults to zero.

t [array_like, optional] Time points. Computed if not given.

n [int, optional] The number of time points to compute (if *t* is not given).

Returns

tout [ndarray] Output time points, as a 1-D array.

yout [tuple of ndarray] Step response of system. Each element of the tuple represents the output of the system based on a step response to each input.

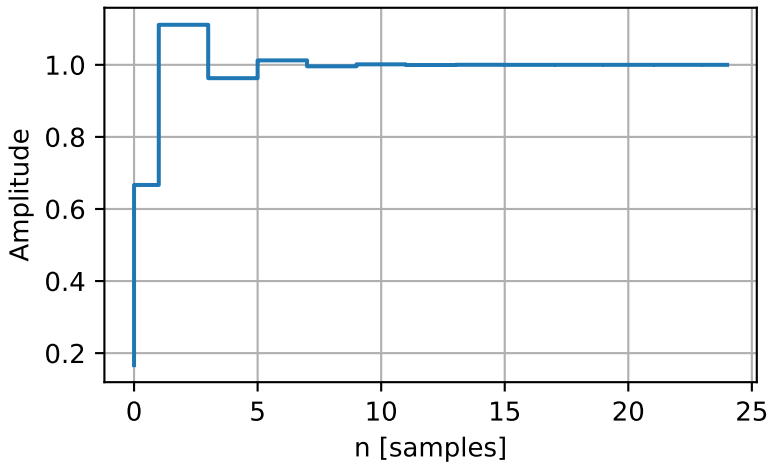
See also:

step, **dimpulse**, **dlsim**, **cont2discrete**

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> butter = signal.dlti(*signal.butter(3, 0.5))
>>> t, y = signal.dstep(butter, n=25)
>>> plt.step(t, np.squeeze(y))
>>> plt.grid()
>>> plt.xlabel('n [samples]')
>>> plt.ylabel('Amplitude')
```



scipy.signal.dfreqresp

scipy.signal.**dfreqresp**(*system*, *w=None*, *n=10000*, *whole=False*)

Calculate the frequency response of a discrete-time system.

Parameters

system [an instance of the *dlti* class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
- 1 (instance of *dlti*)
- 2 (numerator, denominator, dt)
- 3 (zeros, poles, gain, dt)
- 4 (A, B, C, D, dt)

w [array_like, optional] Array of frequencies (in radians/sample). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

n [int, optional] Number of frequency points to compute if *w* is not given. The *n* frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

whole [bool, optional] Normally, if 'w' is not given, frequencies are computed from 0 to the Nyquist frequency, pi radians/sample (upper-half of unit-circle). If *whole* is True, compute frequencies from 0 to 2*pi radians/sample.

Returns

w	[1D ndarray] Frequency array [radians/sample]
H	[1D ndarray] Array of complex magnitude values

Notes

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. `z^2 + 3z + 5` would be represented as `[1, 3, 5]`).

New in version 0.18.0.

Examples

Generating the Nyquist plot of a transfer function

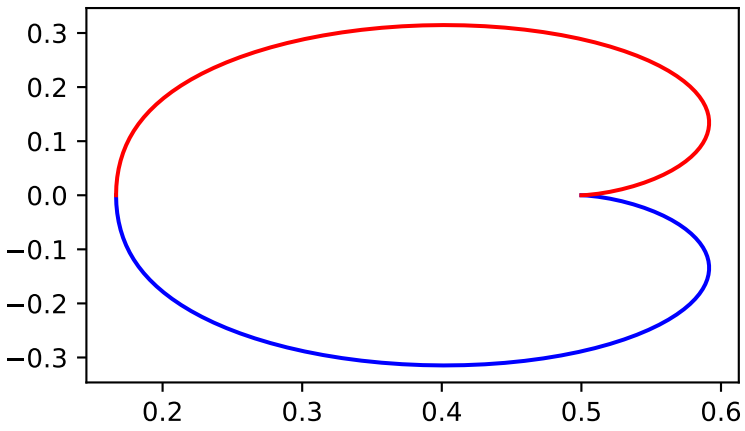
```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Construct the transfer function $H(z) = \frac{1}{z^2+2z+3}$ with a sampling time of 0.05 seconds:

```
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.05)
```

```
>>> w, H = signal.dfreqresp(sys)
```

```
>>> plt.figure()
>>> plt.plot(H.real, H.imag, "b")
>>> plt.plot(H.real, -H.imag, "r")
>>> plt.show()
```



scipy.signal.dbode

scipy.signal.**dbode**(*system*, *w=None*, *n=100*)

Calculate Bode magnitude and phase data of a discrete-time system.

Parameters

system [an instance of the LTI class or a tuple describing the system.] The following gives the number of elements in the tuple and the interpretation:
- 1 (instance of *dlti*)
- 2 (num, den, dt)
- 3 (zeros, poles, gain, dt)
- 4 (A, B, C, D, dt)

w [array_like, optional] Array of frequencies (in radians/sample). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

n [int, optional] Number of frequency points to compute if *w* is not given. The *n* frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

Returns

w [1D ndarray] Frequency array [rad/time_unit]

mag [1D ndarray] Magnitude array [dB]

phase [1D ndarray] Phase array [deg]

Notes

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. `z^2 + 3z + 5` would be represented as `[1, 3, 5]`).

New in version 0.18.0.

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Construct the transfer function $H(z) = \frac{1}{z^2+2z+3}$ with a sampling time of 0.05 seconds:

```
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.05)
```

Equivalent: sys.bode()

```
>>> w, mag, phase = signal.dbode(sys)
```

```
>>> plt.figure()
>>> plt.semilogx(w, mag)    # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()

LTI representations

tf2zpk(b, a)	Return zero, pole, gain (z, p, k) representation from a numerator, denominator representation of a linear filter.
tf2sos(b, a[, pairing])	Return second-order sections from transfer function representation
tf2ss(num, den)	Transfer function to state-space representation.
zpk2tf(z, p, k)	Return polynomial transfer function representation from zeros and poles
zpk2sos(z, p, k[, pairing])	Return second-order sections from zeros, poles, and gain of a system
zpk2ss(z, p, k)	Zero-pole-gain representation to state-space representation
ss2tf(A, B, C, D[, input])	State-space to transfer function.
ss2zpk(A, B, C, D[, input])	State-space representation to zero-pole-gain representation.
sos2zpk(sos)	Return zeros, poles, and gain of a series of second-order sections
sos2tf(sos)	Return a single transfer function from a series of second-order sections
cont2discrete(system, dt[, method, alpha])	Transform a continuous to a discrete state-space system.
place_poles(A, B, poles[, method, rtol, maxiter])	Compute K such that eigenvalues (A - dot(B, K))=poles.

scipy.signal.tf2zpk

scipy.signal.**tf2zpk**(*b*, *a*)

Return zero, pole, gain (z, p, k) representation from a numerator, denominator representation of a linear filter.

Parameters

b [array_like] Numerator polynomial coefficients.

a [array_like] Denominator polynomial coefficients.

Returns

z [ndarray] Zeros of the transfer function.

p [ndarray] Poles of the transfer function.

k [float] System gain.

Notes

If some values of *b* are too close to 0, they are removed. In that case, a BadCoefficients warning is emitted.

The *b* and *a* arrays are interpreted as coefficients for positive, descending powers of the transfer function variable. So the inputs $b = [b_0, b_1, ..., b_M]$ and $a = [a_0, a_1, ..., a_N]$ can represent an analog filter of the form:

$$H(s) = \frac{b_0 s^M + b_1 s^{(M-1)} + \cdots + b_M}{a_0 s^N + a_1 s^{(N-1)} + \cdots + a_N}$$

or a discrete-time filter of the form:

$$H(z) = \frac{b_0 z^M + b_1 z^{(M-1)} + \cdots + b_M}{a_0 z^N + a_1 z^{(N-1)} + \cdots + a_N}$$

This "positive powers" form is found more commonly in controls engineering. If *M* and *N* are equal (which is true for all filters generated by the bilinear transform), then this happens to be equivalent to the "negative powers" discrete-time form preferred in DSP:

$$H(z) = \frac{b_0 + b_1 z^{-1} + \cdots + b_M z^{-M}}{a_0 + a_1 z^{-1} + \cdots + a_N z^{-N}}$$

Although this is true for common filters, remember that this is not true in the general case. If *M* and *N* are not equal, the discrete-time transfer function coefficients must first be converted to the "positive powers" form before finding the poles and zeros.

scipy.signal.tf2sos

`scipy.signal.`**`tf2sos`**(*b*, *a*, *pairing='nearest'*)

Return second-order sections from transfer function representation

Parameters

b [array_like] Numerator polynomial coefficients.

a [array_like] Denominator polynomial coefficients.

pairing [{'nearest', 'keep_odd'}, optional] The method to use to combine pairs of poles and zeros into sections. See *zpk2sos*.

Returns

sos [ndarray] Array of second-order filter coefficients, with shape `(n_sections, 6)`. See *sosfilt* for the SOS filter format specification.

See also:

zpk2sos, **sosfilt**

Notes

It is generally discouraged to convert from TF to SOS format, since doing so usually will not improve numerical precision errors. Instead, consider designing filters in ZPK format and converting directly to SOS. TF is converted to SOS by first converting to ZPK format, then converting ZPK to SOS.

New in version 0.16.0.

scipy.signal.tf2ss

`scipy.signal.`**`tf2ss`**(*num*, *den*)

Transfer function to state-space representation.

Parameters

num, den [array_like] Sequences representing the coefficients of the numerator and denominator polynomials, in order of descending degree. The denominator needs to be at least as long as the numerator.

Returns

A, B, C, D [ndarray] State space representation of the system, in controller canonical form.

Examples

Convert the transfer function:

$$H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1}$$

```
>>> num = [1, 3, 3]
>>> den = [1, 2, 1]
```

to the state-space representation:

$$\dot{\mathbf{x}}(t) = \begin{bmatrix} -2 & -1 \\ 1 & 0 \end{bmatrix} \mathbf{x}(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} \mathbf{u}(t)$$

$$\mathbf{y}(t) = \begin{bmatrix} 1 & 2 \end{bmatrix} \mathbf{x}(t) + \begin{bmatrix} 1 \end{bmatrix} \mathbf{u}(t)$$

```
>>> from scipy.signal import tf2ss
>>> A, B, C, D = tf2ss(num, den)
>>> A
array([[-2., -1.],
       [ 1.,  0.]])
>>> B
array([[ 1.],
       [ 0.]])
>>> C
array([[ 1.,  2.]])
>>> D
array([[ 1.]])
```

scipy.signal.zpk2tf

scipy.signal.**zpk2tf**(*z*, *p*, *k*)

Return polynomial transfer function representation from zeros and poles

Parameters

z	[array_like] Zeros of the transfer function.
p	[array_like] Poles of the transfer function.
k	[float] System gain.

Returns

b	[ndarray] Numerator polynomial coefficients.
a	[ndarray] Denominator polynomial coefficients.

scipy.signal.zpk2sos

scipy.signal.**zpk2sos**(*z*, *p*, *k*, *pairing='nearest'*)

Return second-order sections from zeros, poles, and gain of a system

Parameters

z	[array_like] Zeros of the transfer function.
p	[array_like] Poles of the transfer function.
k	[float] System gain.

pairing [{'nearest', 'keep_odd'}, optional] The method to use to combine pairs of poles and zeros into sections. See Notes below.

Returns

sos [ndarray] Array of second-order filter coefficients, with shape `(n_sections, 6)`. See *`sosfilt`* for the SOS filter format specification.

See also:

`sosfilt`

Notes

The algorithm used to convert ZPK to SOS format is designed to minimize errors due to numerical precision issues. The pairing algorithm attempts to minimize the peak gain of each biquadratic section. This is done by pairing poles with the nearest zeros, starting with the poles closest to the unit circle.

Algorithms

The current algorithms are designed specifically for use with digital filters. (The output coefficients are not correct for analog filters.)

The steps in the `pairing='nearest'` and `pairing='keep_odd'` algorithms are mostly shared. The `nearest` algorithm attempts to minimize the peak gain, while `'keep_odd'` minimizes peak gain under the constraint that odd-order systems should retain one section as first order. The algorithm steps and are as follows:

As a pre-processing step, add poles or zeros to the origin as necessary to obtain the same number of poles and zeros for pairing. If `pairing == 'nearest'` and there are an odd number of poles, add an additional pole and a zero at the origin.

The following steps are then iterated over until no more poles or zeros remain:

1. Take the (next remaining) pole (complex or real) closest to the unit circle to begin a new filter section.
2. If the pole is real and there are no other remaining real poles[1], add the closest real zero to the section and leave it as a first order section. Note that after this step we are guaranteed to be left with an even number of real poles, complex poles, real zeros, and complex zeros for subsequent pairing iterations.
3. Else:
    1. If the pole is complex and the zero is the only remaining real zero*, then pair the pole with the *next* closest zero (guaranteed to be complex). This is necessary to ensure that there will be a real zero remaining to eventually create a first-order section (thus keeping the odd order).
    2. Else pair the pole with the closest remaining zero (complex or real).
    3. Proceed to complete the second-order section by adding another pole and zero to the current pole and zero in the section:
        1. If the current pole and zero are both complex, add their conjugates.
        2. Else if the pole is complex and the zero is real, add the conjugate pole and the next closest real zero.
        3. Else if the pole is real and the zero is complex, add the conjugate zero and the real pole closest to those zeros.
        4. Else (we must have a real pole and real zero) add the next real pole closest to the unit circle, and then add the real zero closest to that pole.

New in version 0.16.0.

[1] This conditional can only be met for specific odd-order inputs with the `pairing == 'keep_odd'` method.

Examples

Design a 6th order low-pass elliptic digital filter for a system with a sampling rate of 8000 Hz that has a pass-band corner frequency of 1000 Hz. The ripple in the pass-band should not exceed 0.087 dB, and the attenuation in the stop-band should be at least 90 dB.

In the following call to *signal.ellip*, we could use `output='sos'`, but for this example, we'll use `output='zpk'`, and then convert to SOS format with *zpk2sos*:

```
>>> from scipy import signal
>>> z, p, k = signal.ellip(6, 0.087, 90, 1000/(0.5*8000), output='zpk')
```

Now convert to SOS format.

```
>>> sos = signal.zpk2sos(z, p, k)
```

The coefficients of the numerators of the sections:

```
>>> sos[:, :3]
array([[ 0.0014154 ,  0.00248707,  0.0014154 ],
       [ 1.        ,  0.72965193,  1.        ],
       [ 1.        ,  0.17594966,  1.        ]])
```

The symmetry in the coefficients occurs because all the zeros are on the unit circle.

The coefficients of the denominators of the sections:

```
>>> sos[:, 3:]
array([[ 1.        , -1.32543251,  0.46989499],
       [ 1.        , -1.26117915,  0.6262586 ],
       [ 1.        , -1.25707217,  0.86199667]])
```

The next example shows the effect of the *pairing* option. We have a system with three poles and three zeros, so the SOS array will have shape (2, 6). The means there is, in effect, an extra pole and an extra zero at the origin in the SOS representation.

```
>>> z1 = np.array([-1, -0.5-0.5j, -0.5+0.5j])
>>> p1 = np.array([0.75, 0.8+0.1j, 0.8-0.1j])
```

With `pairing='nearest'` (the default), we obtain

```
>>> signal.zpk2sos(z1, p1, 1)
array([[ 1.  ,  1.  ,  0.5 ,  1.  , -0.75,  0.  ],
       [ 1.  ,  1.  ,  0.  ,  1.  , -1.6 ,  0.65]])
```

The first section has the zeros {-0.5-0.05j, -0.5+0.5j} and the poles {0, 0.75}, and the second section has the zeros {-1, 0} and poles {0.8+0.1j, 0.8-0.1j}. Note that the extra pole and zero at the origin have been assigned to different sections.

With `pairing='keep_odd'`, we obtain:

```
>>> signal.zpk2sos(z1, p1, 1, pairing='keep_odd')
array([[ 1.  ,  1.  ,  0.  ,  1.  , -0.75,  0.  ],
       [ 1.  ,  1.  ,  0.5 ,  1.  , -1.6 ,  0.65]])
```

The extra pole and zero at the origin are in the same section. The first section is, in effect, a first-order section.

scipy.signal.zpk2ss

scipy.signal.**zpk2ss**(*z*, *p*, *k*)

Zero-pole-gain representation to state-space representation

Parameters

z, p	[sequence] Zeros and poles.
k	[float] System gain.

Returns

A, B, C, D	[ndarray] State space representation of the system, in controller canonical form.

scipy.signal.ss2tf

scipy.signal.**ss2tf**(*A*, *B*, *C*, *D*, *input=0*)

State-space to transfer function.

A, B, C, D defines a linear state-space system with *p* inputs, *q* outputs, and *n* state variables.

Parameters

A	[array_like] State (or system) matrix of shape `(n, n)`
B	[array_like] Input matrix of shape `(n, p)`
C	[array_like] Output matrix of shape `(q, n)`
D	[array_like] Feedthrough (or feedforward) matrix of shape `(q, p)`
input	[int, optional] For multiple-input systems, the index of the input to use.

Returns

num	[2-D ndarray] Numerator(s) of the resulting transfer function(s). *num* has one row for each of the system's outputs. Each row is a sequence representation of the numerator polynomial.
den	[1-D ndarray] Denominator of the resulting transfer function(s). *den* is a sequence representation of the denominator polynomial.

Examples

Convert the state-space representation:

$$\dot{\mathbf{x}}(t) = \begin{bmatrix} -2 & -1 \\ 1 & 0 \end{bmatrix} \mathbf{x}(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} \mathbf{u}(t)$$

$$\mathbf{y}(t) = \begin{bmatrix} 1 & 2 \end{bmatrix} \mathbf{x}(t) + \begin{bmatrix} 1 \end{bmatrix} \mathbf{u}(t)$$

```
>>> A = [[-2, -1], [1, 0]]
>>> B = [[1], [0]]  # 2-D column vector
>>> C = [[1, 2]]    # 2-D row vector
>>> D = 1
```

to the transfer function:

$$H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1}$$

```
>>> from scipy.signal import ss2tf
>>> ss2tf(A, B, C, D)
(array([[1., 3., 3.]]), array([ 1.,  2.,  1.]))
```

scipy.signal.ss2zpk

scipy.signal.**ss2zpk**(*A*, *B*, *C*, *D*, *input=0*)

State-space representation to zero-pole-gain representation.

A, B, C, D defines a linear state-space system with *p* inputs, *q* outputs, and *n* state variables.

Parameters

A	[array_like] State (or system) matrix of shape `(n, n)`
B	[array_like] Input matrix of shape `(n, p)`
C	[array_like] Output matrix of shape `(q, n)`
D	[array_like] Feedthrough (or feedforward) matrix of shape `(q, p)`
input	[int, optional] For multiple-input systems, the index of the input to use.

Returns

z, p	[sequence] Zeros and poles.
k	[float] System gain.

scipy.signal.sos2zpk

scipy.signal.**sos2zpk**(*sos*)

Return zeros, poles, and gain of a series of second-order sections

Parameters

sos	[array_like] Array of second-order filter coefficients, must have shape `(n_sections, 6)`. See *sosfilt* for the SOS filter format specification.

Returns

z	[ndarray] Zeros of the transfer function.
p	[ndarray] Poles of the transfer function.
k	[float] System gain.

Notes

The number of zeros and poles returned will be `n_sections * 2` even if some of these are (effectively) zero.

New in version 0.16.0.

scipy.signal.sos2tf

scipy.signal.**sos2tf**(*sos*)

Return a single transfer function from a series of second-order sections

Parameters

sos	[array_like] Array of second-order filter coefficients, must have shape `(n_sections, 6)`. See *sosfilt* for the SOS filter format specification.

Returns

b	[ndarray] Numerator polynomial coefficients.
a	[ndarray] Denominator polynomial coefficients.

Notes

New in version 0.16.0.

scipy.signal.cont2discrete

scipy.signal.**cont2discrete**(*system*, *dt*, *method='zoh'*, *alpha=None*)

Transform a continuous to a discrete state-space system.

Parameters

system [a tuple describing the system or an instance of `lti`] The following gives the number of elements in the tuple and the interpretation:
- 1: (instance of `lti`)
- 2: (num, den)
- 3: (zeros, poles, gain)
- 4: (A, B, C, D)

dt [float] The discretization time step.

method [str, optional] Which method to use:
- gbt: generalized bilinear transformation
- bilinear: Tustin's approximation ("gbt" with alpha=0.5)
- euler: Euler (or forward differencing) method ("gbt" with alpha=0)
- backward_diff: Backwards differencing ("gbt" with alpha=1.0)
- zoh: zero-order hold (default)
- foh: first-order hold (*versionadded: 1.3.0*)
- impulse: equivalent impulse response (*versionadded: 1.3.0*)

alpha [float within [0, 1], optional] The generalized bilinear transformation weighting parameter, which should only be specified with method="gbt", and is ignored otherwise

Returns

sysd [tuple containing the discrete system] Based on the input type, the output will be of the form
- (num, den, dt) for transfer function input
- (zeros, poles, gain, dt) for zeros-poles-gain input
- (A, B, C, D, dt) for state-space system input

Notes

By default, the routine uses a Zero-Order Hold (zoh) method to perform the transformation. Alternatively, a generalized bilinear transformation may be used, which includes the common Tustin's bilinear approximation, an Euler's method technique, or a backwards differencing technique.

The Zero-Order Hold (zoh) method is based on [1], the generalized bilinear approximation is based on [2] and [3], the First-Order Hold (foh) method is based on [4].

[1], [2], [3], [4]

Examples

We can transform a continuous state-space system to a discrete one:

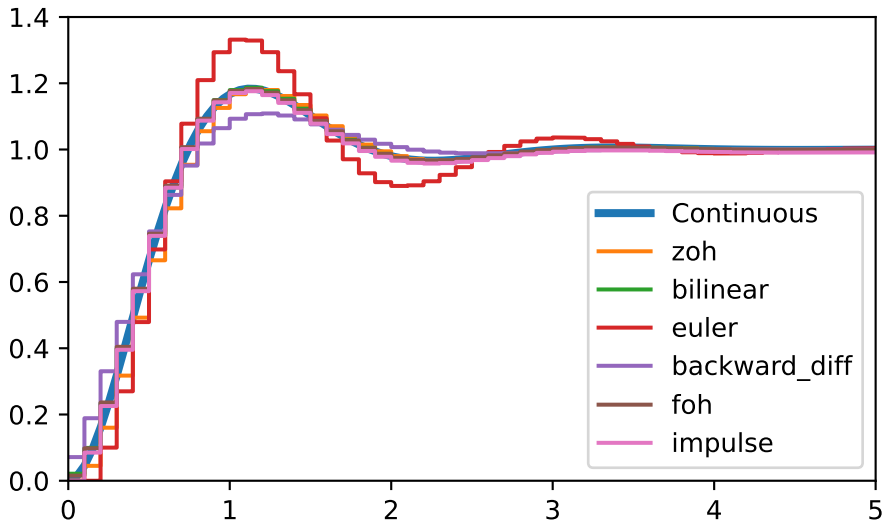
```
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import cont2discrete, lti, dlti, dstep
```

Define a continuous state-space system.

```
>>> A = np.array([[0, 1],[-10., -3]])
>>> B = np.array([[0],[10.]])
>>> C = np.array([[1., 0]])
>>> D = np.array([[0.]])
>>> l_system = lti(A, B, C, D)
>>> t, x = l_system.step(T=np.linspace(0, 5, 100))
>>> fig, ax = plt.subplots()
>>> ax.plot(t, x, label='Continuous', linewidth=3)
```

Transform it to a discrete state-space system using several methods.

```
>>> dt = 0.1
>>> for method in ['zoh', 'bilinear', 'euler', 'backward_diff', 'foh',
↪'impulse']:
...     d_system = cont2discrete((A, B, C, D), dt, method=method)
...     s, x_d = dstep(d_system)
...     ax.step(s, np.squeeze(x_d), label=method, where='post')
>>> ax.axis([t[0], t[-1], x[0], 1.4])
>>> ax.legend(loc='best')
>>> fig.tight_layout()
>>> plt.show()
```



scipy.signal.place_poles

scipy.signal.**place_poles**(*A*, *B*, *poles*, *method='YT'*, *rtol=0.001*, *maxiter=30*)

Compute K such that eigenvalues (A - dot(B, K))=poles.

K is the gain matrix such as the plant described by the linear system `AX+BU` will have its closed-loop poles, i.e the eigenvalues `A - B*K`, as close as possible to those asked for in poles.

SISO, MISO and MIMO systems are supported.

Parameters

A, B [ndarray] State-space representation of linear system `AX + BU`.

poles [array_like] Desired real poles and/or complex conjugates poles. Complex poles are only supported with `method="YT"` (default).

method: {'YT', 'KNV0'}, optional

Which method to choose to find the gain matrix K. One of:

- 'YT': Yang Tits
- 'KNV0': Kautsky, Nichols, Van Dooren update method 0

See References and Notes for details on the algorithms.

rtol: float, optional

After each iteration the determinant of the eigenvectors of `A - B*K` is compared to its previous value, when the relative error between these two values becomes lower than *rtol* the algorithm stops. Default is 1e-3.

maxiter: int, optional

Maximum number of iterations to compute the gain matrix. Default is 30.

Returns

full_state_feedback

[Bunch object]

full_state_feedback is composed of:

gain_matrix

[1-D ndarray] The closed loop matrix K such as the eigenvalues of `A-BK` are as close as possible to the requested poles.

computed_poles

[1-D ndarray] The poles corresponding to `A-BK` sorted as first the real poles in increasing order, then the complex congugates in lexicographic order.

requested_poles

[1-D ndarray] The poles the algorithm was asked to place sorted as above, they may differ from what was achieved.

X [2-D ndarray] The transfer matrix such as `X * diag(poles) = (A - B*K)*X` (see Notes)

rtol [float] The relative tolerance achieved on `det(X)` (see Notes). *rtol* will be NaN if it is possible to solve the system `diag(poles) = (A - B*K)`, or 0 when the optimization algorithms can't do anything i.e when `B.shape[1] == 1`.

nb_iter [int] The number of iterations performed before converging. *nb_iter* will be NaN if it is possible to solve the system `diag(poles) = (A - B*K)`, or 0 when the optimization algorithms can't do anything i.e when `B.shape[1] == 1`.

Notes

The Tits and Yang (YT), [2] paper is an update of the original Kautsky et al. (KNV) paper [1]. KNV relies on rank-1 updates to find the transfer matrix X such that `X * diag(poles) = (A - B*K)*X`, whereas YT uses rank-2 updates. This yields on average more robust solutions (see [2] pp 21-22), furthermore the YT algorithm supports complex poles whereas KNV does not in its original version. Only update method 0 proposed by KNV has been implemented here, hence the name `'KNV0'`.

KNV extended to complex poles is used in Matlab's `place` function, YT is distributed under a non-free licence by Slicot under the name `robpole`. It is unclear and undocumented how KNV0 has been extended to complex poles (Tits and Yang claim on page 14 of their paper that their method can not be used to extend KNV to complex poles), therefore only YT supports them in this implementation.

As the solution to the problem of pole placement is not unique for MIMO systems, both methods start with a tentative transfer matrix which is altered in various way to increase its determinant. Both methods have been proven to converge to a stable solution, however depending on the way the initial transfer matrix is chosen they will converge to different solutions and therefore there is absolutely no guarantee that using `'KNV0'` will yield results similar to Matlab's or any other implementation of these algorithms.

Using the default method `'YT'` should be fine in most cases; `'KNV0'` is only provided because it is needed by `'YT'` in some specific cases. Furthermore `'YT'` gives on average more robust results than `'KNV0'` when `abs(det(X))` is used as a robustness indicator.

[2] is available as a technical report on the following URL: https://hdl.handle.net/1903/5598

[1], [2]

Examples

A simple example demonstrating real pole placement using both KNV and YT algorithms. This is example number 1 from section 4 of the reference KNV publication ([1]):

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> A = np.array([[ 1.380,  -0.2077,  6.715, -5.676  ],
...               [-0.5814, -4.290,   0,      0.6750 ],
...               [ 1.067,   4.273,  -6.654,  5.893  ],
...               [ 0.0480,  4.273,   1.343, -2.104  ]])
>>> B = np.array([[ 0,      5.679 ],
...               [ 1.136,  1.136 ],
...               [ 0,      0,    ],
...               [-3.146,  0     ]])
>>> P = np.array([-0.2, -0.5, -5.0566, -8.6659])
```

Now compute K with KNV method 0, with the default YT method and with the YT method while forcing 100 iterations of the algorithm and print some results after each call.

```
>>> fsf1 = signal.place_poles(A, B, P, method='KNV0')
>>> fsf1.gain_matrix
array([[ 0.20071427, -0.96665799,  0.24066128, -0.10279785],
       [ 0.50587268,  0.57779091,  0.51795763, -0.41991442]])
```

```
>>> fsf2 = signal.place_poles(A, B, P)  # uses YT method
>>> fsf2.computed_poles
array([-8.6659, -5.0566, -0.5   , -0.2   ])
```

```
>>> fsf3 = signal.place_poles(A, B, P, rtol=-1, maxiter=100)
>>> fsf3.X
array([[ 0.52072442+0.j, -0.08409372+0.j, -0.56847937+0.j,  0.74823657+0.
↪j],
       [-0.04977751+0.j, -0.80872954+0.j,  0.13566234+0.j, -0.29322906+0.
↪j],
       [-0.82266932+0.j, -0.19168026+0.j, -0.56348322+0.j, -0.43815060+0.
↪j],
       [ 0.22267347+0.j,  0.54967577+0.j, -0.58387806+0.j, -0.40271926+0.
↪j]])
```

The absolute value of the determinant of X is a good indicator to check the robustness of the results, both `'KNV0'` and `'YT'` aim at maximizing it. Below a comparison of the robustness of the results above:

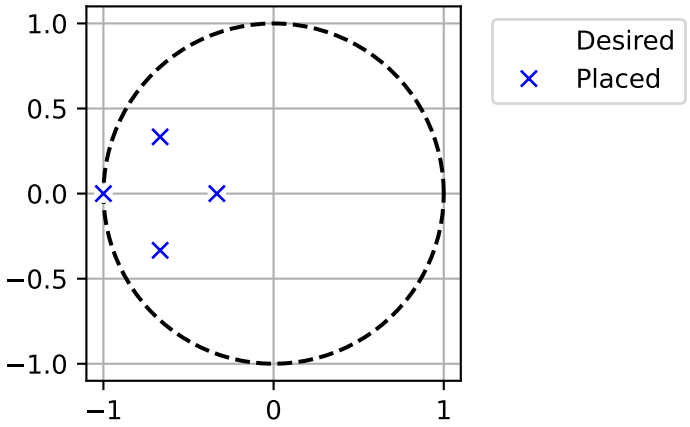
```
>>> abs(np.linalg.det(fsf1.X)) < abs(np.linalg.det(fsf2.X))
True
>>> abs(np.linalg.det(fsf2.X)) < abs(np.linalg.det(fsf3.X))
True
```

Now a simple example for complex poles:

```
>>> A = np.array([[ 0,  7/3.,  0,   0   ],
...               [ 0,   0,    0,  7/9. ],
...               [ 0,   0,    0,   0   ],
...               [ 0,   0,    0,   0   ]])
>>> B = np.array([[ 0,  0 ],
...               [ 0,  0 ],
...               [ 1,  0 ],
...               [ 0,  1 ]])
>>> P = np.array([-3, -1, -2-1j, -2+1j]) / 3.
>>> fsf = signal.place_poles(A, B, P, method='YT')
```

We can plot the desired and computed poles in the complex plane:

```
>>> t = np.linspace(0, 2*np.pi, 401)
>>> plt.plot(np.cos(t), np.sin(t), 'k--')  # unit circle
>>> plt.plot(fsf.requested_poles.real, fsf.requested_poles.imag,
...          'wo', label='Desired')
>>> plt.plot(fsf.computed_poles.real, fsf.computed_poles.imag, 'bx',
...          label='Placed')
>>> plt.grid()
>>> plt.axis('image')
>>> plt.axis([-1.1, 1.1, -1.1, 1.1])
>>> plt.legend(bbox_to_anchor=(1.05, 1), loc=2, numpoints=1)
```



Waveforms

chirp(t, f0, t1, f1[, method, phi, vertex_zero])	Frequency-swept cosine generator.
gausspulse(t[, fc, bw, bwr, tpr, retquad, …])	Return a Gaussian modulated sinusoid:
max_len_seq(nbits[, state, length, taps])	Maximum length sequence (MLS) generator.
sawtooth(t[, width])	Return a periodic sawtooth or triangle waveform.
square(t[, duty])	Return a periodic square-wave waveform.
sweep_poly(t, poly[, phi])	Frequency-swept cosine generator, with a time-dependent frequency.
unit_impulse(shape[, idx, dtype])	Unit impulse signal (discrete delta function) or unit basis vector.

scipy.signal.chirp

scipy.signal.**chirp**(*t*, *f0*, *t1*, *f1*, *method='linear'*, *phi=0*, *vertex_zero=True*)

Frequency-swept cosine generator.

In the following, 'Hz' should be interpreted as 'cycles per unit'; there is no requirement here that the unit is one second. The important distinction is that the units of rotation are cycles, not radians. Likewise, *t* could be a measurement of space instead of time.

Parameters

t [array_like] Times at which to evaluate the waveform.

f0 [float] Frequency (e.g. Hz) at time t=0.

t1 [float] Time at which *f1* is specified.

f1 [float] Frequency (e.g. Hz) of the waveform at time *t1*.

method [{'linear', 'quadratic', 'logarithmic', 'hyperbolic'}, optional] Kind of frequency sweep. If not given, *linear* is assumed. See Notes below for more details.

phi [float, optional] Phase offset, in degrees. Default is 0.

vertex_zero [bool, optional] This parameter is only used when *method* is 'quadratic'. It determines whether the vertex of the parabola that is the graph of the frequency is at t=0 or t=t1.

Returns

y [ndarray] A numpy array containing the signal evaluated at *t* with the requested time-varying frequency. More precisely, the function returns `cos(phase + (pi/180)*phi)` where *phase* is the integral (from 0 to *t*) of `2*pi*f(t)`. `f(t)` is defined below.

See also:

sweep_poly

The graph of the frequency f(t) is a parabola through (0, f0) and (t1, f1). By default, the vertex of the parabola is at (0, f0). If *vertex_zero* is False, then the vertex is at (t1, f1). The formula is:
if vertex_zero is True:

```
f(t) = f0 + (f1 - f0) * t**2 / t1**2
```

else:

```
f(t) = f1 - (f1 - f0) * (t1 - t)**2 / t1**2
```

To use a more general quadratic function, or an arbitrary polynomial, use the function *scipy.signal.sweep_poly*.

logarithmic, log, lo:

```
f(t) = f0 * (f1/f0)**(t/t1)
```

f0 and f1 must be nonzero and have the same sign.
This signal is also known as a geometric or exponential chirp.

hyperbolic, hyp:

```
f(t) = f0*f1*t1 / ((f0 - f1)*t + f1*t1)
```

f0 and f1 must be nonzero.

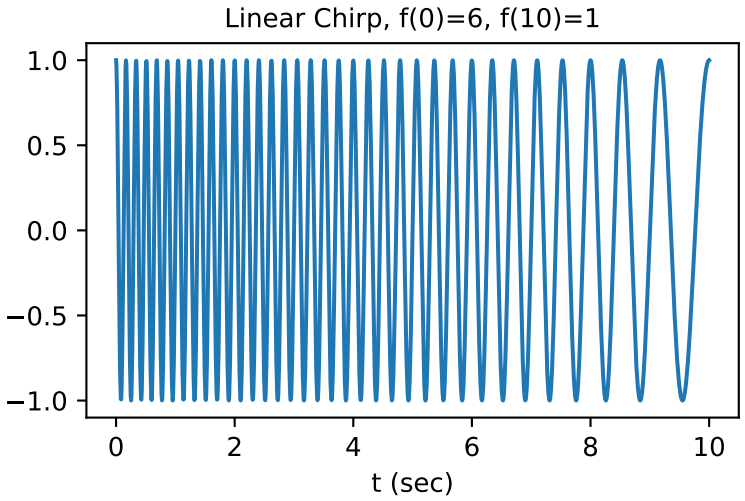
Examples

The following will be used in the examples:

```
>>> from scipy.signal import chirp, spectrogram
>>> import matplotlib.pyplot as plt
```

For the first example, we'll plot the waveform for a linear chirp from 6 Hz to 1 Hz over 10 seconds:

```
>>> t = np.linspace(0, 10, 1500)
>>> w = chirp(t, f0=6, f1=1, t1=10, method='linear')
>>> plt.plot(t, w)
>>> plt.title("Linear Chirp, f(0)=6, f(10)=1")
>>> plt.xlabel('t (sec)')
>>> plt.show()
```



For the remaining examples, we'll use higher frequency ranges, and demonstrate the result using *scipy.signal.spectrogram*. We'll use a 4 second interval sampled at 7200 Hz.

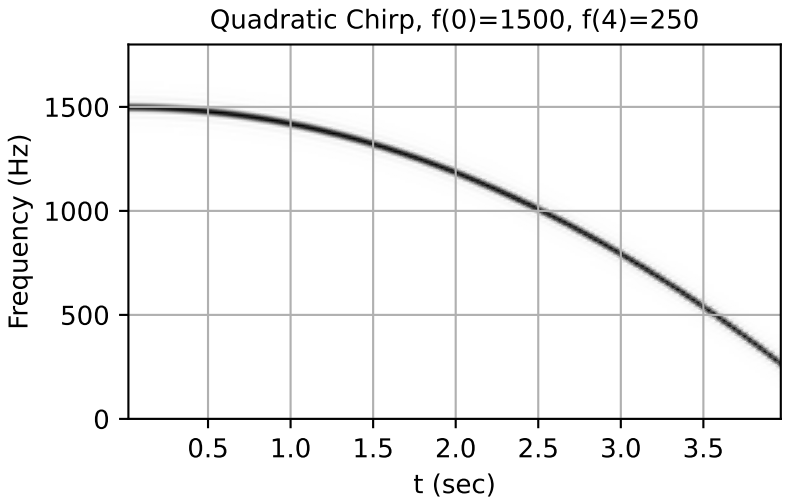
```
>>> fs = 7200
>>> T = 4
>>> t = np.arange(0, int(T*fs)) / fs
```

We'll use this function to plot the spectrogram in each example.

```
>>> def plot_spectrogram(title, w, fs):
...     ff, tt, Sxx = spectrogram(w, fs=fs, nperseg=256, nfft=576)
...     plt.pcolormesh(tt, ff[:145], Sxx[:145], cmap='gray_r', shading=
↪'gouraud')
...     plt.title(title)
...     plt.xlabel('t (sec)')
...     plt.ylabel('Frequency (Hz)')
...     plt.grid()
...
```

Quadratic chirp from 1500 Hz to 250 Hz (vertex of the parabolic curve of the frequency is at t=0):

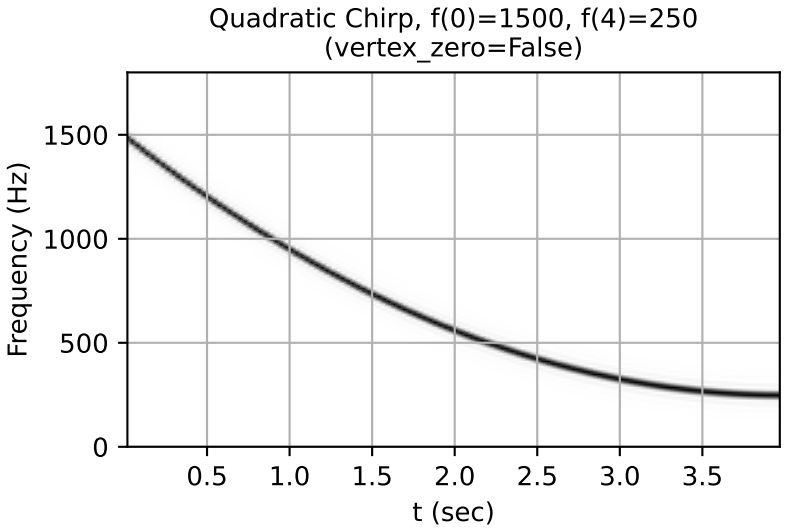
```
>>> w = chirp(t, f0=1500, f1=250, t1=T, method='quadratic')
>>> plot_spectrogram(f'Quadratic Chirp, f(0)=1500, f({T})=250', w, fs)
>>> plt.show()
```



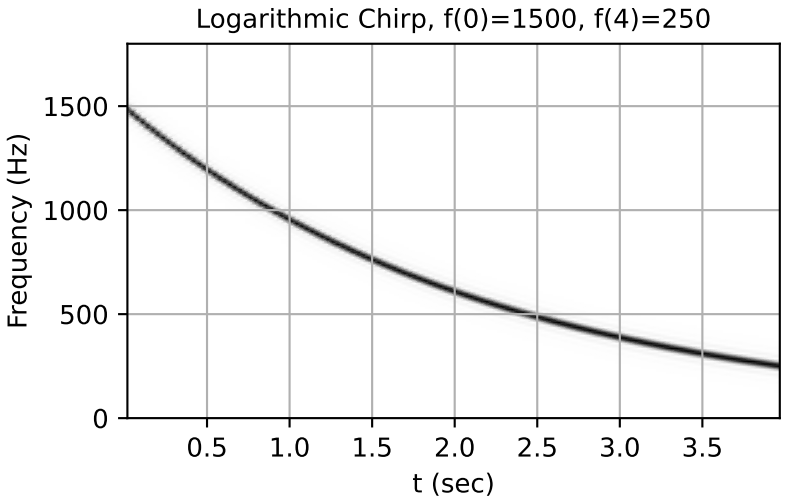
Quadratic chirp from 1500 Hz to 250 Hz (vertex of the parabolic curve of the frequency is at t=T):

```
>>> w = chirp(t, f0=1500, f1=250, t1=T, method='quadratic',
...           vertex_zero=False)
>>> plot_spectrogram(f'Quadratic Chirp, f(0)=1500, f({T})=250\n' +
...                  '(vertex_zero=False)', w, fs)
>>> plt.show()
```

Logarithmic chirp from 1500 Hz to 250 Hz:

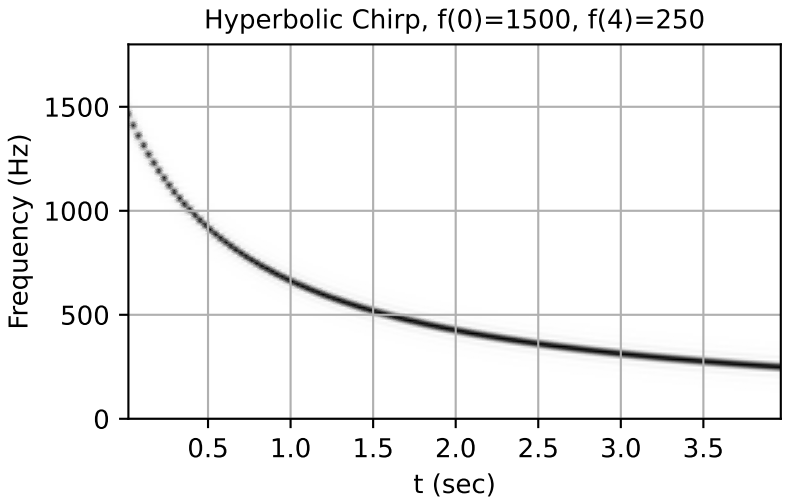


```
>>> w = chirp(t, f0=1500, f1=250, t1=T, method='logarithmic')
>>> plot_spectrogram(f'Logarithmic Chirp, f(0)=1500, f({T})=250', w, fs)
>>> plt.show()
```



Hyperbolic chirp from 1500 Hz to 250 Hz:

```
>>> w = chirp(t, f0=1500, f1=250, t1=T, method='hyperbolic')
>>> plot_spectrogram(f'Hyperbolic Chirp, f(0)=1500, f({T})=250', w, fs)
>>> plt.show()
```



scipy.signal.gausspulse

`scipy.signal.`**`gausspulse`**(*t*, *fc=1000*, *bw=0.5*, *bwr=- 6*, *tpr=- 60*, *retquad=False*, *retenv=False*)

Return a Gaussian modulated sinusoid:

```
exp(-a t^2) exp(1j*2*pi*fc*t).
```

If *retquad* is True, then return the real and imaginary parts (in-phase and quadrature). If *retenv* is True, then return the envelope (unmodulated signal). Otherwise, return the real part of the modulated sinusoid.

Parameters

t	[ndarray or the string 'cutoff'] Input array.
fc	[float, optional] Center frequency (e.g. Hz). Default is 1000.
bw	[float, optional] Fractional bandwidth in frequency domain of pulse (e.g. Hz). Default is 0.5.
bwr	[float, optional] Reference level at which fractional bandwidth is calculated (dB). Default is -6.
tpr	[float, optional] If *t* is 'cutoff', then the function returns the cutoff time for when the pulse amplitude falls below *tpr* (in dB). Default is -60.
retquad	[bool, optional] If True, return the quadrature (imaginary) as well as the real part of the signal. Default is False.
retenv	[bool, optional] If True, return the envelope of the signal. Default is False.

Returns

yI	[ndarray] Real part of signal. Always returned.
yQ	[ndarray] Imaginary part of signal. Only returned if *retquad* is True.
yenv	[ndarray] Envelope of signal. Only returned if *retenv* is True.

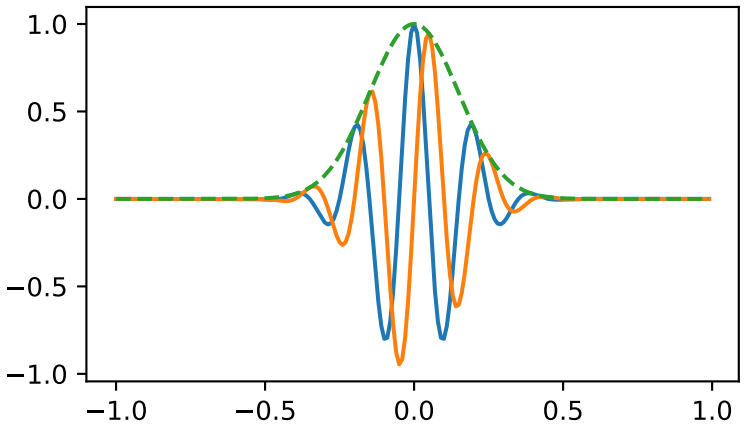
See also:

`scipy.signal.morlet`

Examples

Plot real component, imaginary component, and envelope for a 5 Hz pulse, sampled at 100 Hz for 2 seconds:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 2 * 100, endpoint=False)
>>> i, q, e = signal.gausspulse(t, fc=5, retquad=True, retenv=True)
>>> plt.plot(t, i, t, q, t, e, '--')
```



scipy.signal.max_len_seq

scipy.signal.**max_len_seq**(*nbits*, *state=None*, *length=None*, *taps=None*)

Maximum length sequence (MLS) generator.

Parameters

nbits [int] Number of bits to use. Length of the resulting sequence will be `(2**nbits) - 1`. Note that generating long sequences (e.g., greater than `nbits == 16`) can take a long time.

state [array_like, optional] If array, must be of length `nbits`, and will be cast to binary (bool) representation. If None, a seed of ones will be used, producing a repeatable representation. If `state` is all zeros, an error is raised as this is invalid. Default: None.

length [int, optional] Number of samples to compute. If None, the entire length `(2**nbits) - 1` is computed.

taps [array_like, optional] Polynomial taps to use (e.g., `[7, 6, 1]` for an 8-bit sequence). If None, taps will be automatically selected (for up to `nbits == 32`).

Returns

seq [array] Resulting MLS sequence of 0's and 1's.

state [array] The final state of the shift register.

Notes

The algorithm for MLS generation is generically described in:

https://en.wikipedia.org/wiki/Maximum_length_sequence

The default values for taps are specifically taken from the first option listed for each value of `nbits` in:

https://web.archive.org/web/20181001062252/http://www.newwaveinstruments.com/resources/articles/m_sequence_linear_feedback_shift_register_lfsr.htm

New in version 0.15.0.

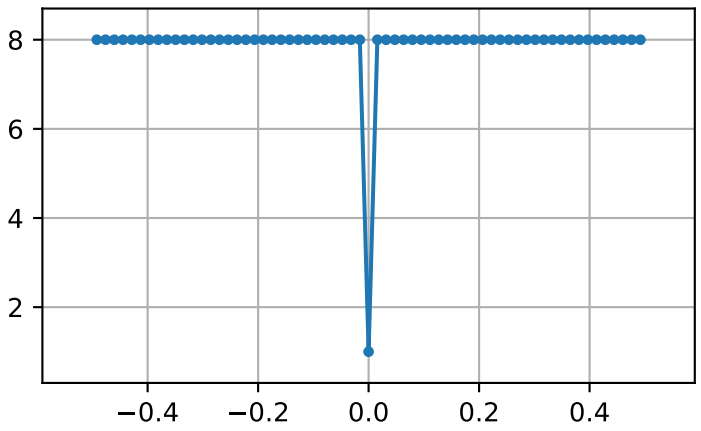
Examples

MLS uses binary convention:

```
>>> from scipy.signal import max_len_seq
>>> max_len_seq(4)[0]
array([1, 1, 1, 1, 0, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0], dtype=int8)
```

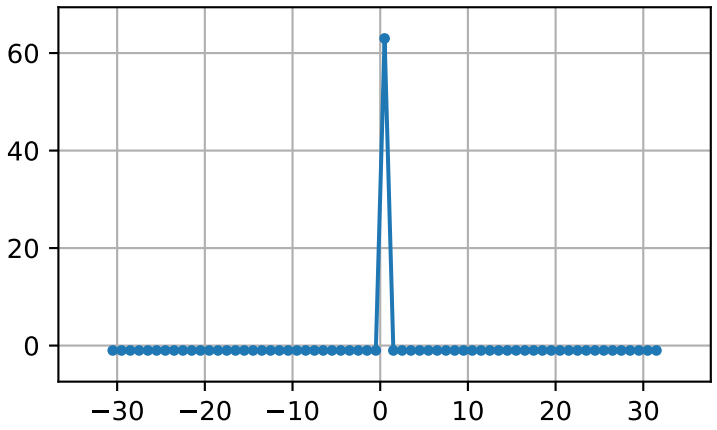
MLS has a white spectrum (except for DC):

```
>>> import matplotlib.pyplot as plt
>>> from numpy.fft import fft, ifft, fftshift, fftfreq
>>> seq = max_len_seq(6)[0]*2-1  # +1 and -1
>>> spec = fft(seq)
>>> N = len(seq)
>>> plt.plot(fftshift(fftfreq(N)), fftshift(np.abs(spec)), '.-')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```



Circular autocorrelation of MLS is an impulse:

```
>>> acorrcirc = ifft(spec * np.conj(spec)).real
>>> plt.figure()
>>> plt.plot(np.arange(-N/2+1, N/2+1), fftshift(acorrcirc), '.-')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```



Linear autocorrelation of MLS is approximately an impulse:

```
>>> acorr = np.correlate(seq, seq, 'full')
>>> plt.figure()
>>> plt.plot(np.arange(-N+1, N), acorr, '.-')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```

scipy.signal.sawtooth

`scipy.signal.`**`sawtooth`**(*t*, *width=1*)

Return a periodic sawtooth or triangle waveform.

The sawtooth waveform has a period `2*pi`, rises from -1 to 1 on the interval 0 to `width*2*pi`, then drops from 1 to -1 on the interval `width*2*pi` to `2*pi`. *width* must be in the interval [0, 1].

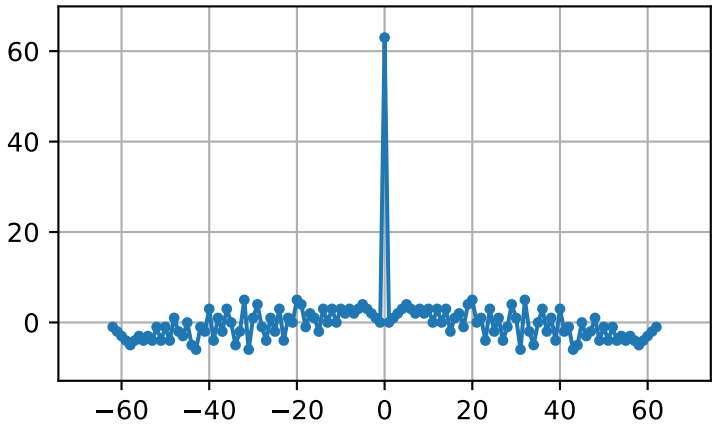
Note that this is not band-limited. It produces an infinite number of harmonics, which are aliased back and forth across the frequency spectrum.

Parameters

t	[array_like] Time.
width	[array_like, optional] Width of the rising ramp as a proportion of the total cycle. Default is 1, producing a rising ramp, while 0 produces a falling ramp. *width* = 0.5 produces a triangle wave. If an array, causes wave shape to change over time, and must be the same length as t.

Returns

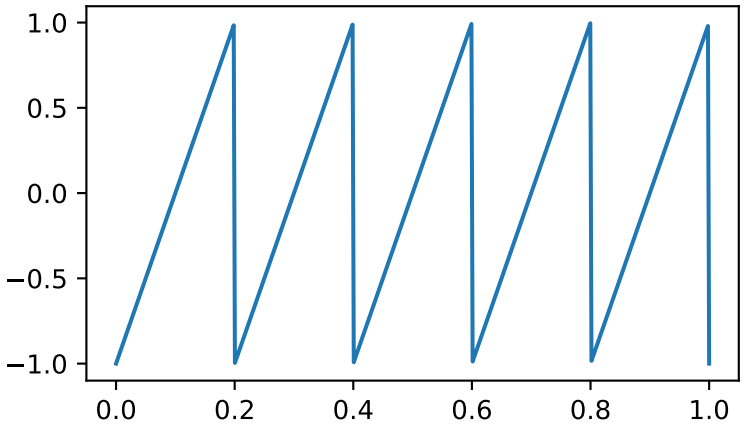
y	[ndarray] Output array containing the sawtooth waveform.



Examples

A 5 Hz waveform sampled at 500 Hz for 1 second:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(0, 1, 500)
>>> plt.plot(t, signal.sawtooth(2 * np.pi * 5 * t))
```



scipy.signal.square

scipy.signal.**square**(*t*, *duty=0.5*)

Return a periodic square-wave waveform.

The square wave has a period `2*pi`, has value +1 from 0 to `2*pi*duty` and -1 from `2*pi*duty` to `2*pi`. *duty* must be in the interval [0,1].

Note that this is not band-limited. It produces an infinite number of harmonics, which are aliased back and forth across the frequency spectrum.

Parameters

t	[array_like] The input time array.
duty	[array_like, optional] Duty cycle. Default is 0.5 (50% duty cycle). If an array, causes wave shape to change over time, and must be the same length as t.

Returns

y	[ndarray] Output array containing the square waveform.

Examples

A 5 Hz waveform sampled at 500 Hz for 1 second:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(0, 1, 500, endpoint=False)
>>> plt.plot(t, signal.square(2 * np.pi * 5 * t))
>>> plt.ylim(-2, 2)
```

A pulse-width modulated sine wave:

```
>>> plt.figure()
>>> sig = np.sin(2 * np.pi * t)
>>> pwm = signal.square(2 * np.pi * 30 * t, duty=(sig + 1)/2)
>>> plt.subplot(2, 1, 1)
>>> plt.plot(t, sig)
>>> plt.subplot(2, 1, 2)
>>> plt.plot(t, pwm)
>>> plt.ylim(-1.5, 1.5)
```

scipy.signal.sweep_poly

scipy.signal.**sweep_poly**(*t*, *poly*, *phi=0*)

Frequency-swept cosine generator, with a time-dependent frequency.

This function generates a sinusoidal function whose instantaneous frequency varies with time. The frequency at time *t* is given by the polynomial *poly*.

Parameters

t	[ndarray] Times at which to evaluate the waveform.

poly	[1-D array_like or instance of numpy.poly1d] The desired frequency expressed as a polynomial. If *poly* is a list or ndarray of length n, then the elements of *poly* are the coefficients of the polynomial, and the instantaneous frequency is
	`f(t) = poly[0]*t**(n-1) + poly[1]*t**(n-2) + ... + poly[n-1]`
	If *poly* is an instance of numpy.poly1d, then the instantaneous frequency is
	`f(t) = poly(t)`

0.0
0.2
0.4
0.6
0.8
1.0

phi [float, optional] Phase offset, in degrees, Default: 0.

Returns

sweep_poly

[ndarray] A numpy array containing the signal evaluated at *t* with the requested time-varying frequency. More precisely, the function returns `cos(phase + (pi/180)*phi)`, where *phase* is the integral (from 0 to t) of `2 * pi * f(t)`; `f(t)` is defined above.

See also:

`chirp`

Notes

New in version 0.8.0.

If *poly* is a list or ndarray of length *n*, then the elements of *poly* are the coefficients of the polynomial, and the instantaneous frequency is:

```
f(t) = poly[0]*t**(n-1) + poly[1]*t**(n-2) + ... + poly[n-1]
```

If *poly* is an instance of `numpy.poly1d`, then the instantaneous frequency is:

```
f(t) = poly(t)
```

Finally, the output *s* is:

```
cos(phase + (pi/180)*phi)
```

where *phase* is the integral from 0 to *t* of `2 * pi * f(t)`, `f(t)` as defined above.

Examples

Compute the waveform with instantaneous frequency:

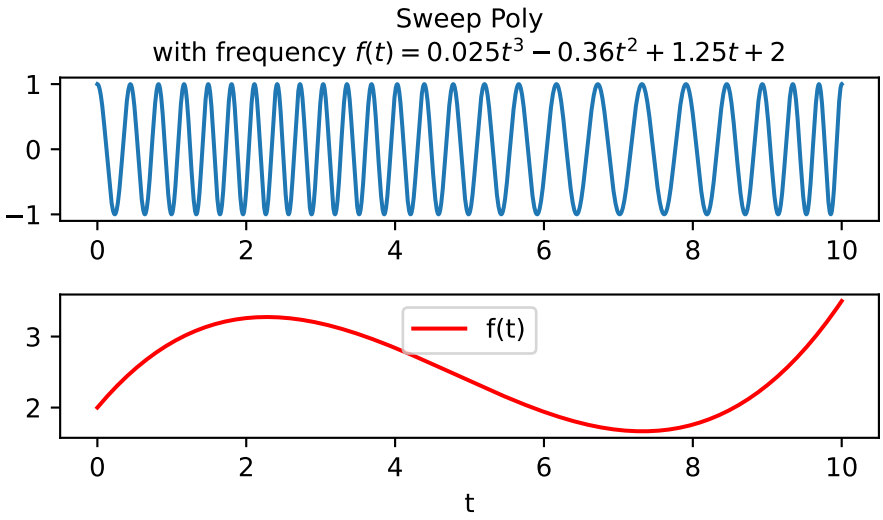
```
f(t) = 0.025*t**3 - 0.36*t**2 + 1.25*t + 2
```

over the interval 0 <= t <= 10.

```
>>> from scipy.signal import sweep_poly
>>> p = np.poly1d([0.025, -0.36, 1.25, 2.0])
>>> t = np.linspace(0, 10, 5001)
>>> w = sweep_poly(t, p)
```

Plot it:

```
>>> import matplotlib.pyplot as plt
>>> plt.subplot(2, 1, 1)
>>> plt.plot(t, w)
>>> plt.title("Sweep Poly\nwith frequency " +
...           "$f(t) = 0.025t^3 - 0.36t^2 + 1.25t + 2$")
>>> plt.subplot(2, 1, 2)
>>> plt.plot(t, p(t), 'r', label='f(t)')
>>> plt.legend()
>>> plt.xlabel('t')
>>> plt.tight_layout()
>>> plt.show()
```



scipy.signal.unit_impulse

`scipy.signal.`**`unit_impulse`**(*shape*, *idx=None*, *dtype=<class 'float'>*)

Unit impulse signal (discrete delta function) or unit basis vector.

Parameters

shape [int or tuple of int] Number of samples in the output (1-D), or a tuple that represents the shape of the output (N-D).

idx [None or int or tuple of int or 'mid', optional] Index at which the value is 1. If None, defaults to the 0th element. If `idx='mid'`, the impulse will be centered at `shape // 2` in all dimensions. If an int, the impulse will be at *idx* in all dimensions.

dtype [data-type, optional] The desired data-type for the array, e.g., `numpy.int8`. Default is `numpy.float64`.

Returns

y [ndarray] Output array containing an impulse signal.

Notes

The 1D case is also known as the Kronecker delta.

New in version 0.19.0.

Examples

An impulse at the 0th element ($\delta[n]$):

```
>>> from scipy import signal
>>> signal.unit_impulse(8)
array([ 1.,  0.,  0.,  0.,  0.,  0.,  0.,  0.])
```

Impulse offset by 2 samples ($\delta[n-2]$):

```
>>> signal.unit_impulse(7, 2)
array([ 0.,  0.,  1.,  0.,  0.,  0.,  0.])
```

2-dimensional impulse, centered:

```
>>> signal.unit_impulse((3, 3), 'mid')
array([[ 0.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  0.]])
```

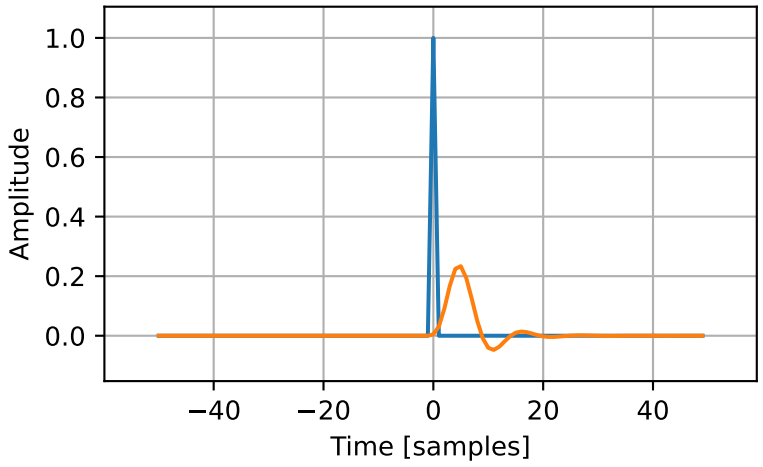
Impulse at (2, 2), using broadcasting:

```
>>> signal.unit_impulse((4, 4), 2)
array([[ 0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  0.],
       [ 0.,  0.,  0.,  0.]])
```

Plot the impulse response of a 4th-order Butterworth lowpass filter:

```
>>> imp = signal.unit_impulse(100, 'mid')
>>> b, a = signal.butter(4, 0.2)
>>> response = signal.lfilter(b, a, imp)
```

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(np.arange(-50, 50), imp)
>>> plt.plot(np.arange(-50, 50), response)
>>> plt.margins(0.1, 0.1)
>>> plt.xlabel('Time [samples]')
>>> plt.ylabel('Amplitude')
>>> plt.grid(True)
>>> plt.show()
```



Window functions

For window functions, see the `scipy.signal.windows` namespace.

In the *scipy.signal* namespace, there is a convenience function to obtain these windows by name:

get_window(window, Nx[, fftbins])	Return a window of a given length and type.

scipy.signal.get_window

scipy.signal.**get_window**(*window*, *Nx*, *fftbins=True*)

Return a window of a given length and type.

Parameters

window [string, float, or tuple] The type of window to create. See below for more details.

Nx [int] The number of samples in the window.

fftbins [bool, optional] If True (default), create a "periodic" window, ready to use with *ifftshift* and be multiplied by the result of an FFT (see also *fftfreq*). If False, create a "symmetric" window, for use in filter design.

Returns

get_window

[ndarray] Returns a window of length *Nx* and type *window*

Notes

Window types:

- `boxcar`
- `triang`
- `blackman`
- `hamming`
- `hann`
- `bartlett`
- `flattop`
- `parzen`
- `bohman`
- `blackmanharris`
- `nuttall`
- `barthann`
- `cosine`
- `exponential`
- `tukey`
- `taylor`
- `kaiser` (needs beta)

- `gaussian` (needs standard deviation)
- `general_cosine` (needs weighting coefficients)
- `general_gaussian` (needs power, width)
- `general_hamming` (needs window coefficient)
- `dpss` (needs normalized half-bandwidth)
- `chebwin` (needs attenuation)

If the window requires no parameters, then *window* can be a string.

If the window requires parameters, then *window* must be a tuple with the first argument the string name of the window, and the next arguments the needed parameters.

If *window* is a floating point number, it is interpreted as the beta parameter of the `kaiser` window.

Each of the window types listed above is also the name of a function that can be called directly to create a window of that type.

Examples

```
>>> from scipy import signal
>>> signal.get_window('triang', 7)
array([ 0.125,  0.375,  0.625,  0.875,  0.875,  0.625,  0.375])
>>> signal.get_window(('kaiser', 4.0), 9)
array([ 0.08848053,  0.29425961,  0.56437221,  0.82160913,  0.97885093,
        0.97885093,  0.82160913,  0.56437221,  0.29425961])
>>> signal.get_window(('exponential', None, 1.), 9)
array([ 0.011109  ,  0.03019738,  0.082085  ,  0.22313016,  0.60653066,
        0.60653066,  0.22313016,  0.082085  ,  0.03019738])
>>> signal.get_window(4.0, 9)
array([ 0.08848053,  0.29425961,  0.56437221,  0.82160913,  0.97885093,
        0.97885093,  0.82160913,  0.56437221,  0.29425961])
```

Wavelets

cascade(hk[, J])	Return (x, phi, psi) at dyadic points `K/2**J` from filter coefficients.
daub(p)	The coefficients for the FIR low-pass filter producing Daubechies wavelets.
morlet(M[, w, s, complete])	Complex Morlet wavelet.
qmf(hk)	Return high-pass qmf filter from low-pass
ricker(points, a)	Return a Ricker wavelet, also known as the “Mexican hat wavelet”.
morlet2(M, s[, w])	Complex Morlet wavelet, designed to work with *cwt*.
cwt(data, wavelet, widths[, dtype])	Continuous wavelet transform.

scipy.signal.cascade

scipy.signal.**cascade**(*hk*, *J=7*)

Return (x, phi, psi) at dyadic points `K/2**J` from filter coefficients.

Parameters

hk	[array_like] Coefficients of low-pass filter.
J	[int, optional] Values will be computed at grid points `K/2**J`. Default is 7.

Returns

x	[ndarray] The dyadic points `K/2**J` for `K=0...N * (2**J)-1` where `len(hk) = len(gk) = N+1`.
phi	[ndarray] The scaling function `phi(x)` at *x*: `phi(x) = sum(hk * phi(2x-k))`, where k is from 0 to N.
psi	[ndarray, optional] The wavelet function `psi(x)` at *x*: `phi(x) = sum(gk * phi(2x-k))`, where k is from 0 to N. *psi* is only returned if *gk* is not None.

Notes

The algorithm uses the vector cascade algorithm described by Strang and Nguyen in "Wavelets and Filter Banks". It builds a dictionary of values and slices for quick reuse. Then inserts vectors into final vector at the end.

scipy.signal.daub

scipy.signal.**daub**(*p*)

The coefficients for the FIR low-pass filter producing Daubechies wavelets.

p>=1 gives the order of the zero at f=1/2. There are 2p filter coefficients.

Parameters

p	[int] Order of the zero at f=1/2, can have values from 1 to 34.

Returns

daub	[ndarray] Return

scipy.signal.morlet

scipy.signal.**morlet**(*M*, *w=5.0*, *s=1.0*, *complete=True*)

Complex Morlet wavelet.

Parameters

M	[int] Length of the wavelet.
w	[float, optional] Omega0. Default is 5
s	[float, optional] Scaling factor, windowed from `-s*2*pi` to `+s*2*pi`. Default is 1.
complete	[bool, optional] Whether to use the complete or the standard version.

Returns

morlet	[(M,) ndarray]

See also:

morlet2

Implementation of Morlet wavelet, compatible with *cwt*.

scipy.signal.gausspulse

Notes

The standard version:

```
pi**-0.25 * exp(1j*w*x) * exp(-0.5*(x**2))
```

This commonly used wavelet is often referred to simply as the Morlet wavelet. Note that this simplified version can cause admissibility problems at low values of *w*.

The complete version:

```
pi**-0.25 * (exp(1j*w*x) - exp(-0.5*(w**2))) * exp(-0.5*(x**2))
```

This version has a correction term to improve admissibility. For *w* greater than 5, the correction term is negligible.

Note that the energy of the return wavelet is not normalised according to *s*.

The fundamental frequency of this wavelet in Hz is given by `f = 2*s*w*r / M` where *r* is the sampling rate.

Note: This function was created before *cwt* and is not compatible with it.

scipy.signal.qmf

`scipy.signal.`**`qmf`**(*hk*)

Return high-pass qmf filter from low-pass

Parameters

hk [array_like] Coefficients of high-pass filter.

scipy.signal.ricker

`scipy.signal.`**`ricker`**(*points*, *a*)

Return a Ricker wavelet, also known as the "Mexican hat wavelet".

It models the function:

```
A * (1 - (x/a)**2) * exp(-0.5*(x/a)**2),
```

where `A = 2/(sqrt(3*a)*(pi**0.25))`.

Parameters

points [int] Number of points in *vector*. Will be centered around 0.
a [scalar] Width parameter of the wavelet.

Returns

vector [(N,) ndarray] Array of length *points* in shape of ricker curve.

Examples

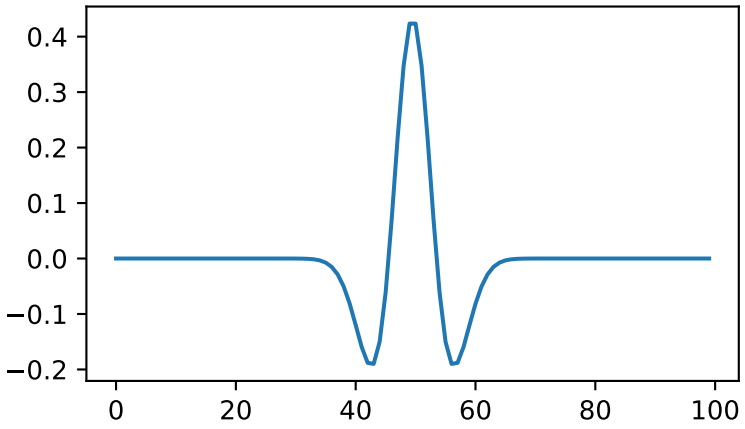
```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> points = 100
>>> a = 4.0
>>> vec2 = signal.ricker(points, a)
>>> print(len(vec2))
100
```

(continues on next page)

(continued from previous page)

```
>>> plt.plot(vec2)
>>> plt.show()
```



scipy.signal.morlet2

scipy.signal.**morlet2**(*M*, *s*, *w=5*)

Complex Morlet wavelet, designed to work with *cwt*.

Returns the complete version of morlet wavelet, normalised according to *s*:

```
exp(1j*w*x/s) * exp(-0.5*(x/s)**2) * pi**(-0.25) * sqrt(1/s)
```

Parameters

M	[int] Length of the wavelet.
s	[float] Width parameter of the wavelet.
w	[float, optional] Omega0. Default is 5

Returns

morlet	[(M,) ndarray]

See also:

morlet

Implementation of Morlet wavelet, incompatible with *cwt*

Notes

New in version 1.4.0.

This function was designed to work with *cwt*. Because *morlet2* returns an array of complex numbers, the *dtype* argument of *cwt* should be set to *complex128* for best results.

Note the difference in implementation with *morlet*. The fundamental frequency of this wavelet in Hz is given by:

```
f = w*fs / (2*s*np.pi)
```

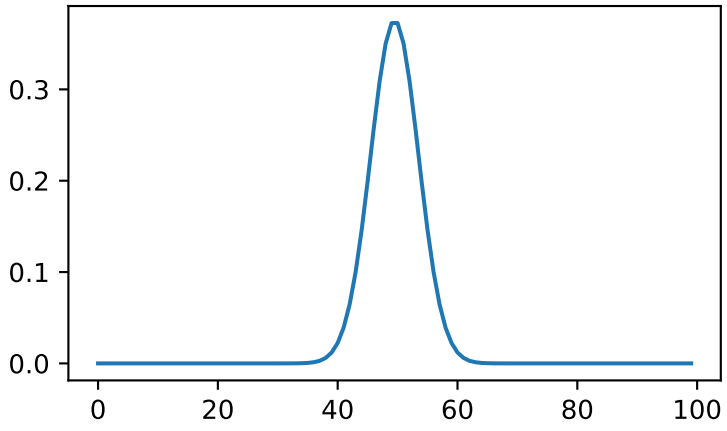
where `fs` is the sampling rate and *s* is the wavelet width parameter. Similarly we can get the wavelet width parameter at `f`:

```
s = w*fs / (2*f*np.pi)
```

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```
>>> M = 100
>>> s = 4.0
>>> w = 2.0
>>> wavelet = signal.morlet2(M, s, w)
>>> plt.plot(abs(wavelet))
>>> plt.show()
```



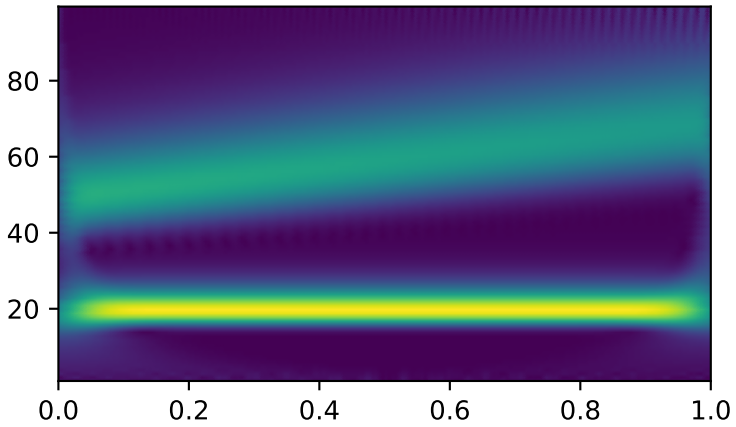
This example shows basic use of *morlet2* with *cwt* in time-frequency analysis:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

(continues on next page)

(continued from previous page)

```
>>> t, dt = np.linspace(0, 1, 200, retstep=True)
>>> fs = 1/dt
>>> w = 6.
>>> sig = np.cos(2*np.pi*(50 + 10*t)*t) + np.sin(40*np.pi*t)
>>> freq = np.linspace(1, fs/2, 100)
>>> widths = w*fs / (2*freq*np.pi)
>>> cwtm = signal.cwt(sig, signal.morlet2, widths, w=w)
>>> plt.pcolormesh(t, freq, np.abs(cwtm), cmap='viridis', shading='gouraud
↪')
>>> plt.show()
```



scipy.signal.cwt

`scipy.signal.`**`cwt`**(*data*, *wavelet*, *widths*, *dtype=None*, ***kwargs*)

Continuous wavelet transform.

Performs a continuous wavelet transform on *data*, using the *wavelet* function. A CWT performs a convolution with *data* using the *wavelet* function, which is characterized by a width parameter and length parameter. The *wavelet* function is allowed to be complex.

Parameters

data	[(N,) ndarray] data on which to perform the transform.
wavelet	[function] Wavelet function, which should take 2 arguments. The first argument is the number of points that the returned vector will have (len(wavelet(length,width)) == length). The second is a width parameter, defining the size of the wavelet (e.g. standard deviation of a gaussian). See *ricker*, which satisfies these requirements.
widths	[(M,) sequence] Widths to use for transform.
dtype	[data-type, optional] The desired data type of output. Defaults to `float64` if the output of *wavelet* is real and `complex128` if it is complex. New in version 1.4.0.
kwargs	Keyword arguments passed to wavelet function. New in version 1.4.0.

Returns

cwt: (M, N) ndarray
Will have shape of (len(widths), len(data)).

Notes

New in version 1.4.0.

For non-symmetric, complex-valued wavelets, the input signal is convolved with the time-reversed complex-conjugate of the wavelet data [1].

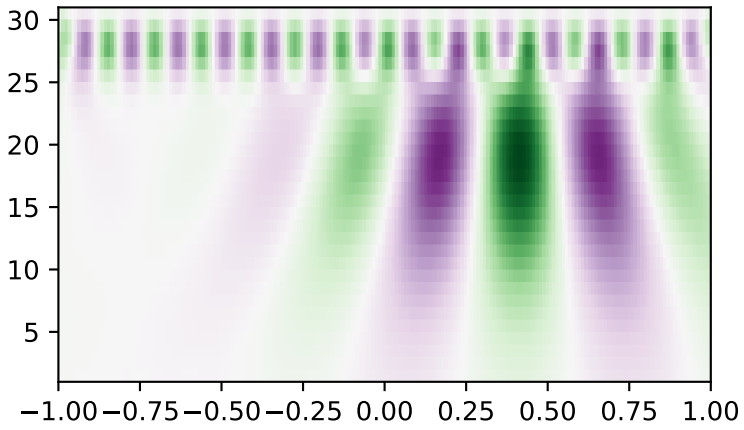
```
length = min(10 * width[ii], len(data))
cwt[ii,:] = signal.convolve(data, np.conj(wavelet(length, width[ii],
                                    **kwargs))[::-1], mode='same')
```

References

[1]

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 200, endpoint=False)
>>> sig  = np.cos(2 * np.pi * 7 * t) + signal.gausspulse(t - 0.4, fc=2)
>>> widths = np.arange(1, 31)
>>> cwtmatr = signal.cwt(sig, signal.ricker, widths)
>>> plt.imshow(cwtmatr, extent=[-1, 1, 1, 31], cmap='PRGn', aspect='auto',
...            vmax=abs(cwtmatr).max(), vmin=-abs(cwtmatr).max())
>>> plt.show()
```



Peak finding

argrelmin(data[, axis, order, mode])	Calculate the relative minima of *data*.
argrelmax(data[, axis, order, mode])	Calculate the relative maxima of *data*.
argrelextrema(data, comparator[, axis, …])	Calculate the relative extrema of *data*.
find_peaks(x[, height, threshold, distance, …])	Find peaks inside a signal based on peak properties.
find_peaks_cwt(vector, widths[, wavelet, …])	Find peaks in a 1-D array with wavelet transformation.
peak_prominences(x, peaks[, wlen])	Calculate the prominence of each peak in a signal.
peak_widths(x, peaks[, rel_height, …])	Calculate the width of each peak in a signal.

scipy.signal.argrelmin

scipy.signal.**argrelmin**(*data*, *axis=0*, *order=1*, *mode='clip'*)

Calculate the relative minima of *data*.

Parameters

data [ndarray] Array in which to find the relative minima.

axis [int, optional] Axis over which to select from *data*. Default is 0.

order [int, optional] How many points on each side to use for the comparison to consider `comparator(n, n+x)` to be True.

mode [str, optional] How the edges of the vector are treated. Available options are 'wrap' (wrap around) or 'clip' (treat overflow as the same as the last (or first) element). Default 'clip'. See numpy.take.

Returns

extrema [tuple of ndarrays] Indices of the minima in arrays of integers. `extrema[k]` is the array of indices of axis *k* of *data*. Note that the return value is a tuple even when *data* is 1-D.

See also:

argrelextrema, **argrelmax**, **find_peaks**

Notes

This function uses *argrelextrema* with np.less as comparator. Therefore, it requires a strict inequality on both sides of a value to consider it a minimum. This means flat minima (more than one sample wide) are not detected. In case of 1-D *data* *find_peaks* can be used to detect all local minima, including flat ones, by calling it with negated *data*.

New in version 0.11.0.

Examples

```
>>> from scipy.signal import argrelmin
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelmin(x)
(array([1, 5]),)
>>> y = np.array([[1, 2, 1, 2],
...               [2, 2, 0, 0],
...               [5, 3, 4, 4]])
...
```

(continues on next page)

(continued from previous page)

```
>>> argrelmin(y, axis=1)
(array([0, 2]), array([2, 1]))
```

scipy.signal.argrelmax

scipy.signal.**argrelmax**(*data*, *axis=0*, *order=1*, *mode='clip'*)

Calculate the relative maxima of *data*.

Parameters

data	[ndarray] Array in which to find the relative maxima.
axis	[int, optional] Axis over which to select from *data*. Default is 0.
order	[int, optional] How many points on each side to use for the comparison to consider `comparator(n, n+x)` to be True.
mode	[str, optional] How the edges of the vector are treated. Available options are 'wrap' (wrap around) or 'clip' (treat overflow as the same as the last (or first) element). Default 'clip'. See `numpy.take`.

Returns

extrema	[tuple of ndarrays] Indices of the maxima in arrays of integers. `extrema[k]` is the array of indices of axis *k* of *data*. Note that the return value is a tuple even when *data* is 1-D.

See also:

argrelextrema, **argrelmin**, **find_peaks**

Notes

This function uses *argrelextrema* with np.greater as comparator. Therefore, it requires a strict inequality on both sides of a value to consider it a maximum. This means flat maxima (more than one sample wide) are not detected. In case of 1-D *data* *find_peaks* can be used to detect all local maxima, including flat ones.

New in version 0.11.0.

Examples

```
>>> from scipy.signal import argrelmax
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelmax(x)
(array([3, 6]),)
>>> y = np.array([[1, 2, 1, 2],
...               [2, 2, 0, 0],
...               [5, 3, 4, 4]])
...
>>> argrelmax(y, axis=1)
(array([0]), array([1]))
```

scipy.signal.argrelextrema

scipy.signal.**argrelextrema**(*data*, *comparator*, *axis=0*, *order=1*, *mode='clip'*)

Calculate the relative extrema of *data*.

Parameters

data [ndarray] Array in which to find the relative extrema.

comparator [callable] Function to use to compare two data points. Should take two arrays as arguments.

axis [int, optional] Axis over which to select from *data*. Default is 0.

order [int, optional] How many points on each side to use for the comparison to consider `comparator(n, n+x)` to be True.

mode [str, optional] How the edges of the vector are treated. 'wrap' (wrap around) or 'clip' (treat overflow as the same as the last (or first) element). Default is 'clip'. See `numpy.take`.

Returns

extrema [tuple of ndarrays] Indices of the maxima in arrays of integers. `extrema[k]` is the array of indices of axis *k* of *data*. Note that the return value is a tuple even when *data* is 1-D.

See also:

argrelmin, **argrelmax**

Notes

New in version 0.11.0.

Examples

```
>>> from scipy.signal import argrelextrema
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelextrema(x, np.greater)
(array([3, 6]),)
>>> y = np.array([[1, 2, 1, 2],
...               [2, 2, 0, 0],
...               [5, 3, 4, 4]])
...
>>> argrelextrema(y, np.less, axis=1)
(array([0, 2]), array([2, 1]))
```

scipy.signal.find_peaks

scipy.signal.**find_peaks**(*x*, *height=None*, *threshold=None*, *distance=None*, *prominence=None*, *width=None*, *wlen=None*, *rel_height=0.5*, *plateau_size=None*)

Find peaks inside a signal based on peak properties.

This function takes a 1-D array and finds all local maxima by simple comparison of neighboring values. Optionally, a subset of these peaks can be selected by specifying conditions for a peak's properties.

Parameters

x [sequence] A signal with peaks.

height [number or ndarray or sequence, optional] Required height of peaks. Either a number, `None`, an array matching *x* or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required height.

threshold [number or ndarray or sequence, optional] Required threshold of peaks, the vertical distance to its neighboring samples. Either a number, `None`, an array matching *x* or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required threshold.

distance [number, optional] Required minimal horizontal distance (>= 1) in samples between neighbouring peaks. Smaller peaks are removed first until the condition is fulfilled for all remaining peaks.

prominence
[number or ndarray or sequence, optional] Required prominence of peaks. Either a number, `None`, an array matching *x* or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required prominence.

width [number or ndarray or sequence, optional] Required width of peaks in samples. Either a number, `None`, an array matching *x* or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied, as the maximal required width.

wlen [int, optional] Used for calculation of the peaks prominences, thus it is only used if one of the arguments *prominence* or *width* is given. See argument *wlen* in `peak_prominences` for a full description of its effects.

rel_height [float, optional] Used for calculation of the peaks width, thus it is only used if *width* is given. See argument *rel_height* in `peak_widths` for a full description of its effects.

plateau_size
[number or ndarray or sequence, optional] Required size of the flat top of peaks in samples. Either a number, `None`, an array matching *x* or a 2-element sequence of the former. The first element is always interpreted as the minimal and the second, if supplied as the maximal required plateau size.
New in version 1.2.0.

Returns

peaks [ndarray] Indices of peaks in *x* that satisfy all given conditions.

properties [dict] A dictionary containing properties of the returned peaks which were calculated as intermediate results during evaluation of the specified conditions:

- **'peak_heights'**
  If *height* is given, the height of each peak in *x*.
- **'left_thresholds', 'right_thresholds'**
  If *threshold* is given, these keys contain a peaks vertical distance to its neighbouring samples.
- **'prominences', 'right_bases', 'left_bases'**
  If *prominence* is given, these keys are accessible. See `peak_prominences` for a description of their content.
- **'width_heights', 'left_ips', 'right_ips'**
  If *width* is given, these keys are accessible. See `peak_widths` for a description of their content.
- **'plateau_sizes', left_edges', 'right_edges'**
  If *plateau_size* is given, these keys are accessible and contain the indices of a peak's edges (edges are still part of the plateau) and the calculated plateau sizes.
  New in version 1.2.0.

To calculate and return properties without excluding peaks, provide the open interval `(None, None)` as a value to the appropriate argument (excluding *distance*).

Warns

PeakPropertyWarning
Raised if a peak's properties have unexpected values (see `peak_prominences` and `peak_widths`).

Warning: This function may return unexpected results for data containing NaNs. To avoid this, NaNs should either be removed or replaced.

See also:

`find_peaks_cwt`

Find peaks using the wavelet transformation.

`peak_prominences`

Directly calculate the prominence of peaks.

`peak_widths`

Directly calculate the width of peaks.

Notes

In the context of this function, a peak or local maximum is defined as any sample whose two direct neighbours have a smaller amplitude. For flat peaks (more than one sample of equal amplitude wide) the index of the middle sample is returned (rounded down in case the number of samples is even). For noisy signals the peak locations can be off because the noise might change the position of local maxima. In those cases consider smoothing the signal before searching for peaks or use other peak finding and fitting methods (like *find_peaks_cwt*).

Some additional comments on specifying conditions:

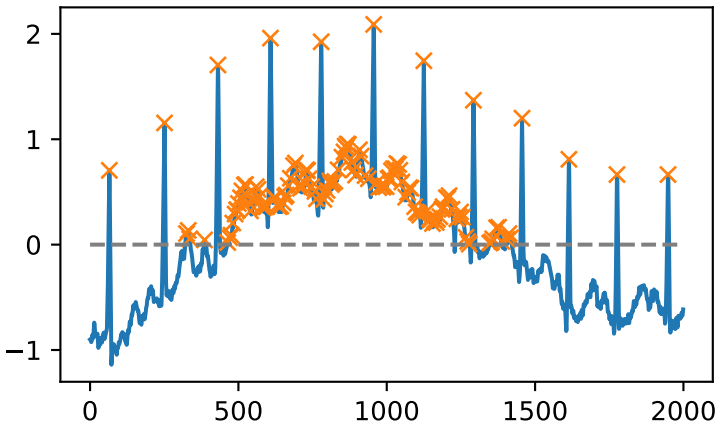
- Almost all conditions (excluding *distance*) can be given as half-open or closed intervals, e.g., `1` or `(1, None)` defines the half-open interval $[1, \infty]$ while `(None, 1)` defines the interval $[-\infty, 1]$. The open interval `(None, None)` can be specified as well, which returns the matching properties without exclusion of peaks.
- The border is always included in the interval used to select valid peaks.
- For several conditions the interval borders can be specified with arrays matching *x* in shape which enables dynamic constrains based on the sample position.
- The conditions are evaluated in the following order: *plateau_size*, *height*, *threshold*, *distance*, *prominence*, *width*. In most cases this order is the fastest one because faster operations are applied first to reduce the number of peaks that need to be evaluated later.
- While indices in *peaks* are guaranteed to be at least *distance* samples apart, edges of flat peaks may be closer than the allowed *distance*.
- Use *wlen* to reduce the time it takes to evaluate the conditions for *prominence* or *width* if *x* is large or has many local maxima (see *peak_prominences*).

New in version 1.1.0.

Examples

To demonstrate this function's usage we use a signal *x* supplied with SciPy (see *scipy.misc.electrocardiogram*). Let's find all peaks (local maxima) in *x* whose amplitude lies above 0.

```
>>> import matplotlib.pyplot as plt
>>> from scipy.misc import electrocardiogram
>>> from scipy.signal import find_peaks
>>> x = electrocardiogram()[2000:4000]
>>> peaks, _ = find_peaks(x, height=0)
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.plot(np.zeros_like(x), "--", color="gray")
>>> plt.show()
```



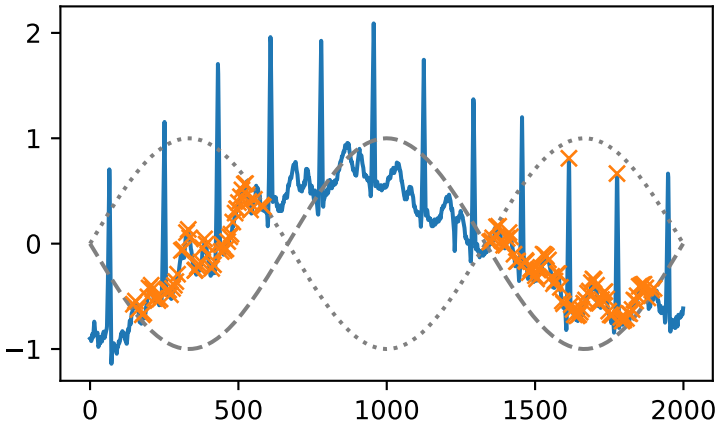
We can select peaks below 0 with `height=(None, 0)` or use arrays matching *x* in size to reflect a changing condition for different parts of the signal.

```
>>> border = np.sin(np.linspace(0, 3 * np.pi, x.size))
>>> peaks, _ = find_peaks(x, height=(-border, border))
>>> plt.plot(x)
>>> plt.plot(-border, "--", color="gray")
>>> plt.plot(border, ":", color="gray")
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.show()
```

Another useful condition for periodic signals can be given with the *distance* argument. In this case, we can easily select the positions of QRS complexes within the electrocardiogram (ECG) by demanding a distance of at least 150 samples.

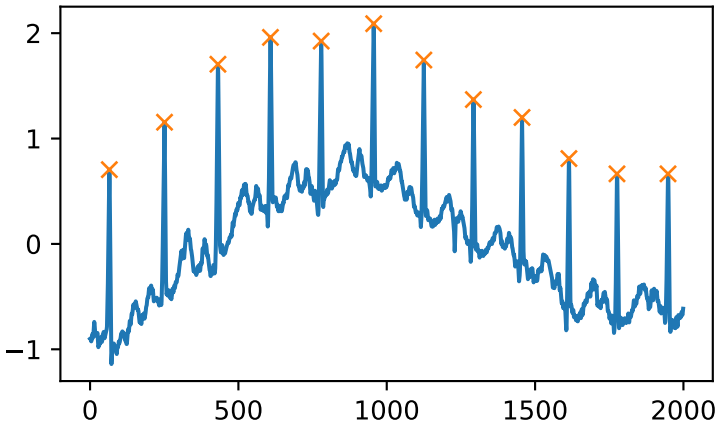
```
>>> peaks, _ = find_peaks(x, distance=150)
>>> np.diff(peaks)
array([186, 180, 177, 171, 177, 169, 167, 164, 158, 162, 172])
>>> plt.plot(x)
```

(continues on next page)



(continued from previous page)

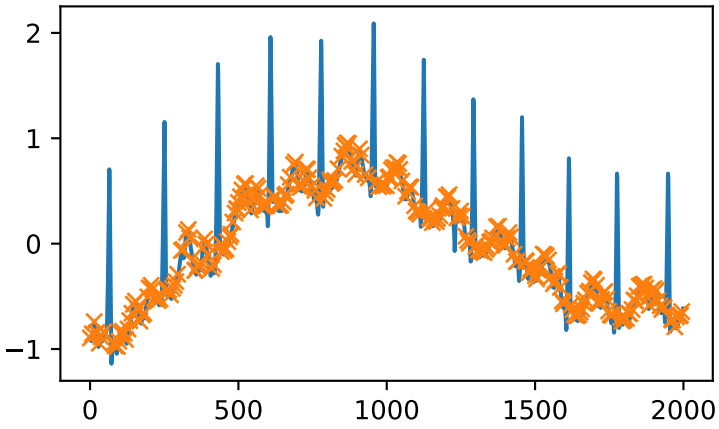
```
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.show()
```



Especially for noisy signals peaks can be easily grouped by their prominence (see *peak_prominences*). E.g., we can select all peaks except for the mentioned QRS complexes by limiting the allowed prominence to 0.6.

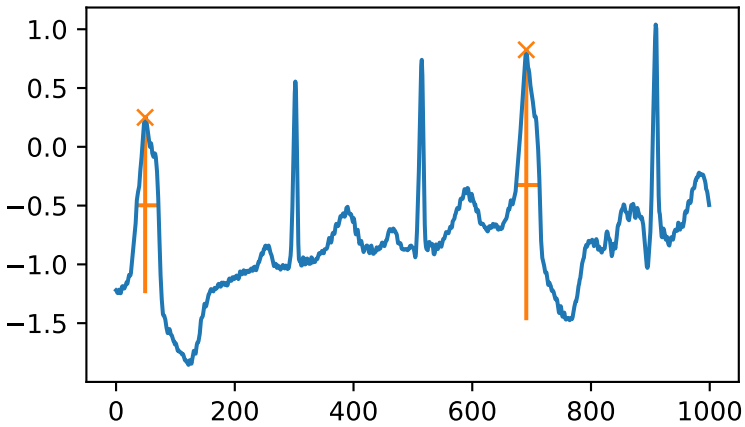
```
>>> peaks, properties = find_peaks(x, prominence=(None, 0.6))
>>> properties["prominences"].max()
0.5049999999999999
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.show()
```

And, finally, let's examine a different section of the ECG which contains beat forms of different shape. To select



only the atypical heart beats, we combine two conditions: a minimal prominence of 1 and width of at least 20 samples.

```
>>> x = electrocardiogram()[17000:18000]
>>> peaks, properties = find_peaks(x, prominence=1, width=20)
>>> properties["prominences"], properties["widths"]
(array([1.495, 2.3  ]), array([36.93773946, 39.32723577]))
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.vlines(x=peaks, ymin=x[peaks] - properties["prominences"],
...            ymax = x[peaks], color = "C1")
>>> plt.hlines(y=properties["width_heights"], xmin=properties["left_ips"],
...            xmax=properties["right_ips"], color = "C1")
>>> plt.show()
```



scipy.signal.find_peaks_cwt

scipy.signal.**find_peaks_cwt**(*vector*, *widths*, *wavelet=None*, *max_distances=None*, *gap_thresh=None*, *min_length=None*, *min_snr=1*, *noise_perc=10*, *window_size=None*)

Find peaks in a 1-D array with wavelet transformation.

The general approach is to smooth *vector* by convolving it with *wavelet(width)* for each width in *widths*. Relative maxima which appear at enough length scales, and with sufficiently high SNR, are accepted.

Parameters

vector [ndarray] 1-D array in which to find the peaks.

widths [float or sequence] Single width or 1-D array-like of widths to use for calculating the CWT matrix. In general, this range should cover the expected width of peaks of interest.

wavelet [callable, optional] Should take two parameters and return a 1-D array to convolve with *vector*. The first parameter determines the number of points of the returned wavelet array, the second parameter is the scale (*width*) of the wavelet. Should be normalized and symmetric. Default is the ricker wavelet.

max_distances
[ndarray, optional] At each row, a ridge line is only connected if the relative max at row[n] is within `max_distances[n]` from the relative max at `row[n+1]`. Default value is `widths/4`.

gap_thresh
[float, optional] If a relative maximum is not found within *max_distances*, there will be a gap. A ridge line is discontinued if there are more than *gap_thresh* points without connecting a new relative maximum. Default is the first value of the widths array i.e. widths[0].

min_length
[int, optional] Minimum length a ridge line needs to be acceptable. Default is `cwt.shape[0] / 4`, ie 1/4-th the number of widths.

min_snr [float, optional] Minimum SNR ratio. Default 1. The signal is the value of the cwt matrix at the shortest length scale (`cwt[0, loc]`), the noise is the *noise_perc`th percentile of datapoints contained within a window of `window_size* around `cwt[0, loc]`.

noise_perc
[float, optional] When calculating the noise floor, percentile of data points examined below which to consider noise. Calculated using *stats.scoreatpercentile*. Default is 10.

window_size
[int, optional] Size of window to use to calculate noise floor. Default is `cwt.shape[1] / 20`.

Returns

peaks_indices
[ndarray] Indices of the locations in the *vector* where peaks were found. The list is sorted.

See also:

cwt

Continuous wavelet transform.

find_peaks

Find peaks inside a signal based on peak properties.

Notes

This approach was designed for finding sharp peaks among noisy data, however with proper parameter selection it should function well for different peak shapes.

The algorithm is as follows:

1. Perform a continuous wavelet transform on *vector*, for the supplied *widths*. This is a convolution of *vector* with *wavelet(width)* for each width in *widths*. See `cwt`.
2. Identify "ridge lines" in the cwt matrix. These are relative maxima at each row, connected across adjacent rows. See identify_ridge_lines
3. Filter the ridge_lines using filter_ridge_lines.

New in version 0.11.0.

References

[1]

Examples

```
>>> from scipy import signal
>>> xs = np.arange(0, np.pi, 0.05)
>>> data = np.sin(xs)
>>> peakind = signal.find_peaks_cwt(data, np.arange(1,10))
>>> peakind, xs[peakind], data[peakind]
([32], array([ 1.6]), array([ 0.9995736]))
```

scipy.signal.peak_prominences

`scipy.signal.`**`peak_prominences`**(*x*, *peaks*, *wlen=None*)

Calculate the prominence of each peak in a signal.

The prominence of a peak measures how much a peak stands out from the surrounding baseline of the signal and is defined as the vertical distance between the peak and its lowest contour line.

Parameters

x [sequence] A signal with peaks.

peaks [sequence] Indices of peaks in *x*.

wlen [int, optional] A window length in samples that optionally limits the evaluated area for each peak to a subset of *x*. The peak is always placed in the middle of the window therefore the given length is rounded up to the next odd integer. This parameter can speed up the calculation (see Notes).

Returns

prominences
[ndarray] The calculated prominences for each peak in *peaks*.

left_bases, right_bases
[ndarray] The peaks' bases as indices in *x* to the left and right of each peak. The higher base of each pair is a peak's lowest contour line.

Raises

ValueError
If a value in *peaks* is an invalid index for *x*.

Warns

PeakPropertyWarning
For indices in *peaks* that don't point to valid local maxima in *x*, the returned prominence will be 0 and this warning is raised. This also happens if *wlen* is smaller than the plateau size of a peak.

Warning: This function may return unexpected results for data containing NaNs. To avoid this, NaNs should either be removed or replaced.

See also:

`find_peaks`

Find peaks inside a signal based on peak properties.

`peak_widths`

Calculate the width of peaks.

Notes

Strategy to compute a peak's prominence:

1. Extend a horizontal line from the current peak to the left and right until the line either reaches the window border (see *wlen*) or intersects the signal again at the slope of a higher peak. An intersection with a peak of the same height is ignored.
2. On each side find the minimal signal value within the interval defined above. These points are the peak's bases.
3. The higher one of the two bases marks the peak's lowest contour line. The prominence can then be calculated as the vertical difference between the peaks height itself and its lowest contour line.

Searching for the peak's bases can be slow for large *x* with periodic behavior because large chunks or even the full signal need to be evaluated for the first algorithmic step. This evaluation area can be limited with the parameter *wlen* which restricts the algorithm to a window around the current peak and can shorten the calculation time if the window length is short in relation to *x*. However, this may stop the algorithm from finding the true global contour line if the peak's true bases are outside this window. Instead, a higher contour line is found within the restricted window leading to a smaller calculated prominence. In practice, this is only relevant for the highest set of peaks in *x*. This behavior may even be used intentionally to calculate "local" prominences.

New in version 1.1.0.

References

[1]

Examples

```
>>> from scipy.signal import find_peaks, peak_prominences
>>> import matplotlib.pyplot as plt
```

Create a test signal with two overlayed harmonics

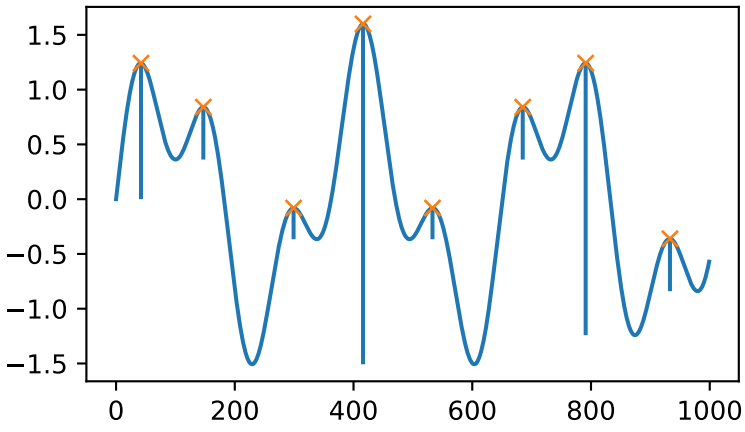
```
>>> x = np.linspace(0, 6 * np.pi, 1000)
>>> x = np.sin(x) + 0.6 * np.sin(2.6 * x)
```

Find all peaks and calculate prominences

```
>>> peaks, _ = find_peaks(x)
>>> prominences = peak_prominences(x, peaks)[0]
>>> prominences
array([1.24159486, 0.47840168, 0.28470524, 3.10716793, 0.284603  ,
       0.47822491, 2.48340261, 0.47822491])
```

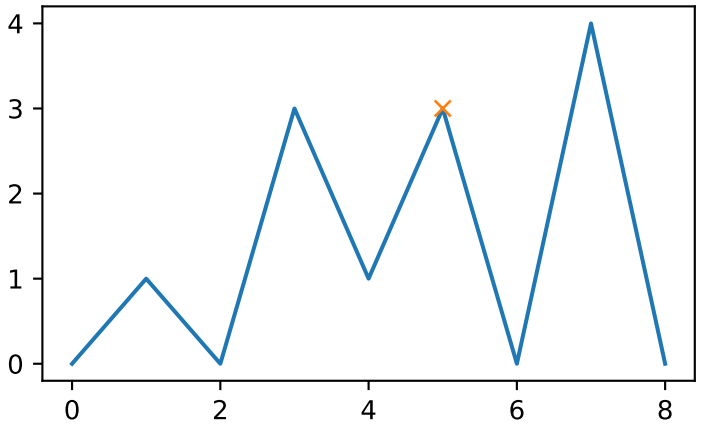
Calculate the height of each peak's contour line and plot the results

```
>>> contour_heights = x[peaks] - prominences
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.vlines(x=peaks, ymin=contour_heights, ymax=x[peaks])
>>> plt.show()
```



Let's evaluate a second example that demonstrates several edge cases for one peak at index 5.

```
>>> x = np.array([0, 1, 0, 3, 1, 3, 0, 4, 0])
>>> peaks = np.array([5])
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.show()
```



```
>>> peak_prominences(x, peaks)  # -> (prominences, left_bases, right_
↪bases)
(array([3.]), array([2]), array([6]))
```

Note how the peak at index 3 of the same height is not considered as a border while searching for the left base. Instead, two minima at 0 and 2 are found in which case the one closer to the evaluated peak is always chosen. On the right side, however, the base must be placed at 6 because the higher peak represents the right border to the evaluated area.

```
>>> peak_prominences(x, peaks, wlen=3.1)
(array([2.]), array([4]), array([6]))
```

Here, we restricted the algorithm to a window from 3 to 7 (the length is 5 samples because *wlen* was rounded up to the next odd integer). Thus, the only two candidates in the evaluated area are the two neighboring samples and a smaller prominence is calculated.

scipy.signal.peak_widths

`scipy.signal.`**`peak_widths`**(*x*, *peaks*, *rel_height=0.5*, *prominence_data=None*, *wlen=None*)

Calculate the width of each peak in a signal.

This function calculates the width of a peak in samples at a relative distance to the peak's height and prominence.

Parameters

x	[sequence] A signal with peaks.
peaks	[sequence] Indices of peaks in *x*.
rel_height	[float, optional] Chooses the relative height at which the peak width is measured as a percentage of its prominence. 1.0 calculates the width of the peak at its lowest contour line

while 0.5 evaluates at half the prominence height. Must be at least 0. See notes for further explanation.

prominence_data
: [tuple, optional] A tuple of three arrays matching the output of `peak_prominences` when called with the same arguments *x* and *peaks*. This data are calculated internally if not provided.

wlen
: [int, optional] A window length in samples passed to `peak_prominences` as an optional argument for internal calculation of *prominence_data*. This argument is ignored if *prominence_data* is given.

Returns

widths
: [ndarray] The widths for each peak in samples.

width_heights
: [ndarray] The height of the contour lines at which the *widths* where evaluated.

left_ips, right_ips
: [ndarray] Interpolated positions of left and right intersection points of a horizontal line at the respective evaluation height.

Raises

ValueError
: If *prominence_data* is supplied but doesn't satisfy the condition `0 <= left_base <= peak <= right_base < x.shape[0]` for each peak, has the wrong dtype, is not C-contiguous or does not have the same shape.

Warns

PeakPropertyWarning
: Raised if any calculated width is 0. This may stem from the supplied *prominence_data* or if *rel_height* is set to 0.

Warning: This function may return unexpected results for data containing NaNs. To avoid this, NaNs should either be removed or replaced.

See also:

`find_peaks`

Find peaks inside a signal based on peak properties.

`peak_prominences`

Calculate the prominence of peaks.

Notes

The basic algorithm to calculate a peak's width is as follows:

- Calculate the evaluation height h_{eval} with the formula $h_{eval} = h_{Peak} - P \cdot R$, where h_{Peak} is the height of the peak itself, P is the peak's prominence and R a positive ratio specified with the argument *rel_height*.
- Draw a horizontal line at the evaluation height to both sides, starting at the peak's current vertical position until the lines either intersect a slope, the signal border or cross the vertical position of the peak's base (see `peak_prominences` for an definition). For the first case, intersection with the signal, the true intersection point is estimated with linear interpolation.

- Calculate the width as the horizontal distance between the chosen endpoints on both sides. As a consequence of this the maximal possible width for each peak is the horizontal distance between its bases.

As shown above to calculate a peak's width its prominence and bases must be known. You can supply these yourself with the argument *prominence_data*. Otherwise, they are internally calculated (see *peak_prominences*).

New in version 1.1.0.

Examples

```
>>> from scipy.signal import chirp, find_peaks, peak_widths
>>> import matplotlib.pyplot as plt
```

Create a test signal with two overlayed harmonics

```
>>> x = np.linspace(0, 6 * np.pi, 1000)
>>> x = np.sin(x) + 0.6 * np.sin(2.6 * x)
```

Find all peaks and calculate their widths at the relative height of 0.5 (contour line at half the prominence height) and 1 (at the lowest contour line at full prominence height).

```
>>> peaks, _ = find_peaks(x)
>>> results_half = peak_widths(x, peaks, rel_height=0.5)
>>> results_half[0]  # widths
array([ 64.25172825,  41.29465463,  35.46943289, 104.71586081,
        35.46729324,  41.30429622, 181.93835853,  45.37078546])
>>> results_full = peak_widths(x, peaks, rel_height=1)
>>> results_full[0]  # widths
array([181.9396084 ,  72.99284945,  61.28657872, 373.84622694,
    61.78404617,  72.48822812, 253.09161876,  79.36860878])
```

Plot signal, peaks and contour lines at which the widths where calculated

```
>>> plt.plot(x)
>>> plt.plot(peaks, x[peaks], "x")
>>> plt.hlines(*results_half[1:], color="C2")
>>> plt.hlines(*results_full[1:], color="C3")
>>> plt.show()
```

Spectral analysis

periodogram(x[, fs, window, nfft, detrend, …])	Estimate power spectral density using a periodogram.
welch(x[, fs, window, nperseg, noverlap, …])	Estimate power spectral density using Welch's method.
csd(x, y[, fs, window, nperseg, noverlap, …])	Estimate the cross power spectral density, Pxy, using Welch's method.
coherence(x, y[, fs, window, nperseg, …])	Estimate the magnitude squared coherence estimate, Cxy, of discrete-time signals X and Y using Welch's method.
spectrogram(x[, fs, window, nperseg, …])	Compute a spectrogram with consecutive Fourier transforms.
lombscargle(x, y, freqs)	Computes the Lomb-Scargle periodogram.

continues on next page

Table 173 – continued from previous page

`vectorstrength`(events, period)	Determine the vector strength of the events corresponding to the given period.
`stft`(x[, fs, window, nperseg, noverlap, …])	Compute the Short Time Fourier Transform (STFT).
`istft`(Zxx[, fs, window, nperseg, noverlap, …])	Perform the inverse Short Time Fourier transform (iSTFT).
`check_COLA`(window, nperseg, noverlap[, tol])	Check whether the Constant OverLap Add (COLA) constraint is met.
`check_NOLA`(window, nperseg, noverlap[, tol])	Check whether the Nonzero Overlap Add (NOLA) constraint is met.

scipy.signal.periodogram

scipy.signal.**periodogram**(*x*, *fs=1.0*, *window='boxcar'*, *nfft=None*, *detrend='constant'*, *return_onesided=True*, *scaling='density'*, *axis=- 1*)

Estimate power spectral density using a periodogram.

Parameters

x [array_like] Time series of measurement values

fs [float, optional] Sampling frequency of the *x* time series. Defaults to 1.0.

window [str or tuple or array_like, optional] Desired window to use. If *window* is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If *window* is array_like it will be used directly as the window and its length must be nperseg. Defaults to 'boxcar'.

nfft [int, optional] Length of the FFT used. If *None* the length of *x* will be used.

detrend [str or function or *False*, optional] Specifies how to detrend each segment. If `detrend` is a string, it is passed as the *type* argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is *False*, no detrending is done. Defaults to 'constant'.

return_onesided [bool, optional] If *True*, return a one-sided spectrum for real data. If *False* return a two-sided spectrum. Defaults to *True*, but for complex data, a two-sided spectrum is always returned.

scaling [{ 'density', 'spectrum' }, optional] Selects between computing the power spectral density ('density') where *Pxx* has units of V**2/Hz and computing the power spectrum ('spectrum') where *Pxx* has units of V**2, if *x* is measured in V and *fs* is measured in Hz. Defaults to 'density'

axis [int, optional] Axis along which the periodogram is computed; the default is over the last axis (i.e. `axis=-1`).

Returns

f [ndarray] Array of sample frequencies.

Pxx [ndarray] Power spectral density or power spectrum of *x*.

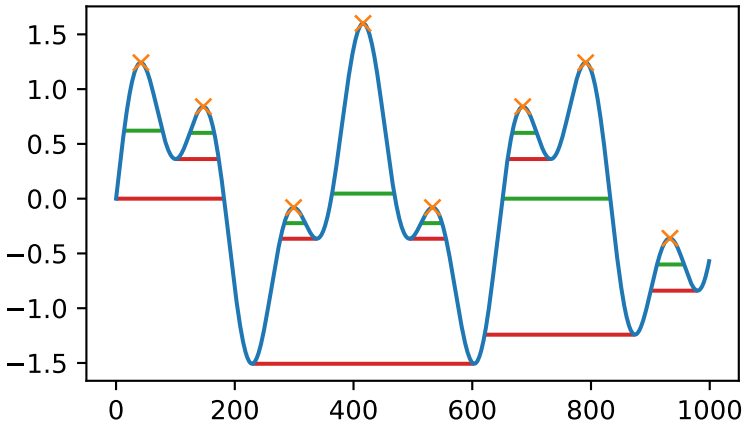
welch

Estimate power spectral density using Welch's method

lombscargle

Lomb-Scargle periodogram for unevenly sampled data



Notes

New in version 0.12.0.

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
```

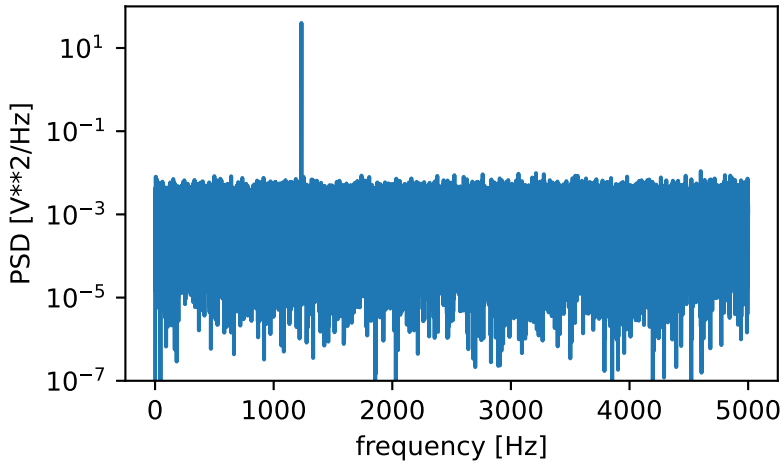
Generate a test signal, a 2 Vrms sine wave at 1234 Hz, corrupted by 0.001 V**2/Hz of white noise sampled at 10 kHz.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2*np.sqrt(2)
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> x = amp*np.sin(2*np.pi*freq*time)
>>> x += rng.normal(scale=np.sqrt(noise_power), size=time.shape)
```

Compute and plot the power spectral density.

```
>>> f, Pxx_den = signal.periodogram(x, fs)
>>> plt.semilogy(f, Pxx_den)
>>> plt.ylim([1e-7, 1e2])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.show()
```

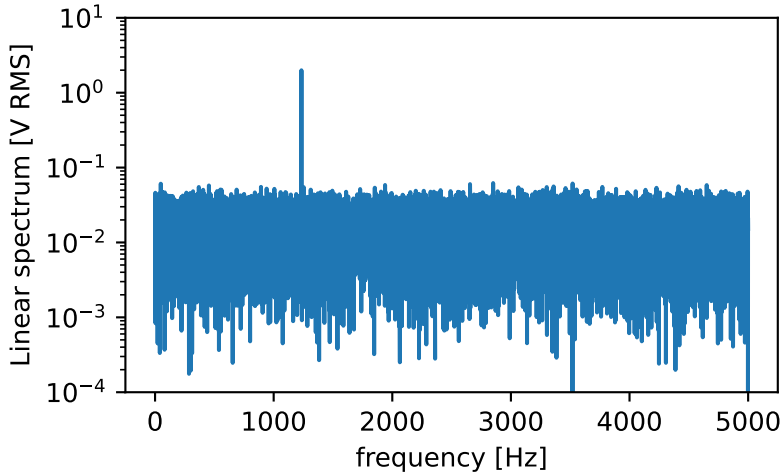
If we average the last half of the spectral density, to exclude the peak, we can recover the noise power on the signal.



```
>>> np.mean(Pxx_den[25000:])
0.000985320699252543
```

Now compute and plot the power spectrum.

```
>>> f, Pxx_spec = signal.periodogram(x, fs, 'flattop', scaling='spectrum')
>>> plt.figure()
>>> plt.semilogy(f, np.sqrt(Pxx_spec))
>>> plt.ylim([1e-4, 1e1])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Linear spectrum [V RMS]')
>>> plt.show()
```



The peak height in the power spectrum is an estimate of the RMS amplitude.

```
>>> np.sqrt(Pxx_spec.max())
2.0077340678640727
```

scipy.signal.welch

scipy.signal.**welch**(*x*, *fs=1.0*, *window='hann'*, *nperseg=None*, *noverlap=None*, *nfft=None*, *detrend='constant'*, *return_onesided=True*, *scaling='density'*, *axis=-1*, *average='mean'*)

Estimate power spectral density using Welch's method.

Welch's method [1] computes an estimate of the power spectral density by dividing the data into overlapping segments, computing a modified periodogram for each segment and averaging the periodograms.

Parameters

x [array_like] Time series of measurement values

fs [float, optional] Sampling frequency of the *x* time series. Defaults to 1.0.

window [str or tuple or array_like, optional] Desired window to use. If *window* is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If *window* is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.

nperseg [int, optional] Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.

noverlap [int, optional] Number of points to overlap between segments. If *None*, `noverlap = nperseg // 2`. Defaults to *None*.

nfft [int, optional] Length of the FFT used, if a zero padded FFT is desired. If *None*, the FFT length is *nperseg*. Defaults to *None*.

detrend [str or function or *False*, optional] Specifies how to detrend each segment. If `detrend` is a string, it is passed as the *type* argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is *False*, no detrending is done. Defaults to 'constant'.

return_onesided [bool, optional] If *True*, return a one-sided spectrum for real data. If *False* return a two-sided spectrum. Defaults to *True*, but for complex data, a two-sided spectrum is always returned.

scaling [{ 'density', 'spectrum' }, optional] Selects between computing the power spectral density ('density') where *Pxx* has units of V**2/Hz and computing the power spectrum ('spectrum') where *Pxx* has units of V**2, if *x* is measured in V and *fs* is measured in Hz. Defaults to 'density'

axis [int, optional] Axis along which the periodogram is computed; the default is over the last axis (i.e. `axis=-1`).

average [{ 'mean', 'median' }, optional] Method to use when averaging periodograms. Defaults to 'mean'.
New in version 1.2.0.

Returns

f [ndarray] Array of sample frequencies.

Pxx [ndarray] Power spectral density or power spectrum of x.

See also:

`periodogram`

Simple, optionally modified periodogram

lombscargle

Lomb-Scargle periodogram for unevenly sampled data

Notes

An appropriate amount of overlap will depend on the choice of window and on your requirements. For the default Hann window an overlap of 50% is a reasonable trade off between accurately estimating the signal power, while not over counting any of the data. Narrower windows may require a larger overlap.

If *noverlap* is 0, this method is equivalent to Bartlett's method [2].

New in version 0.12.0.

References

[1], [2]

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
```

Generate a test signal, a 2 Vrms sine wave at 1234 Hz, corrupted by 0.001 V**2/Hz of white noise sampled at 10 kHz.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2*np.sqrt(2)
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> x = amp*np.sin(2*np.pi*freq*time)
>>> x += rng.normal(scale=np.sqrt(noise_power), size=time.shape)
```

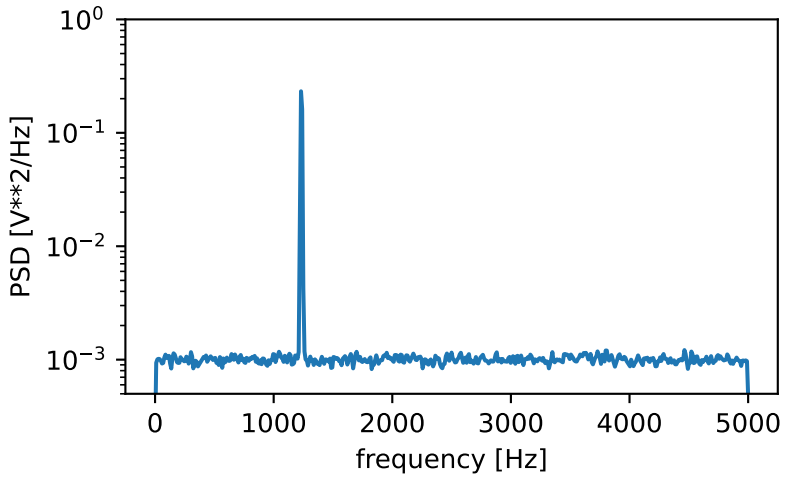
Compute and plot the power spectral density.

```
>>> f, Pxx_den = signal.welch(x, fs, nperseg=1024)
>>> plt.semilogy(f, Pxx_den)
>>> plt.ylim([0.5e-3, 1])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.show()
```

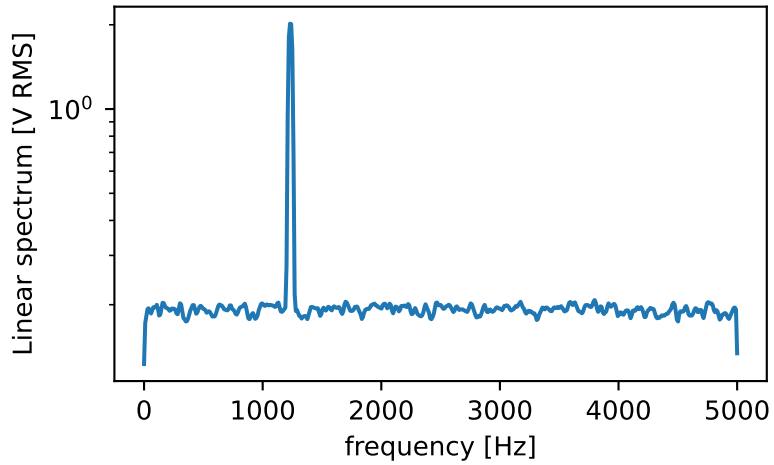
If we average the last half of the spectral density, to exclude the peak, we can recover the noise power on the signal.

```
>>> np.mean(Pxx_den[256:])
0.0009924865443739191
```

Now compute and plot the power spectrum.



```
>>> f, Pxx_spec = signal.welch(x, fs, 'flattop', 1024, scaling='spectrum')
>>> plt.figure()
>>> plt.semilogy(f, np.sqrt(Pxx_spec))
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Linear spectrum [V RMS]')
>>> plt.show()
```

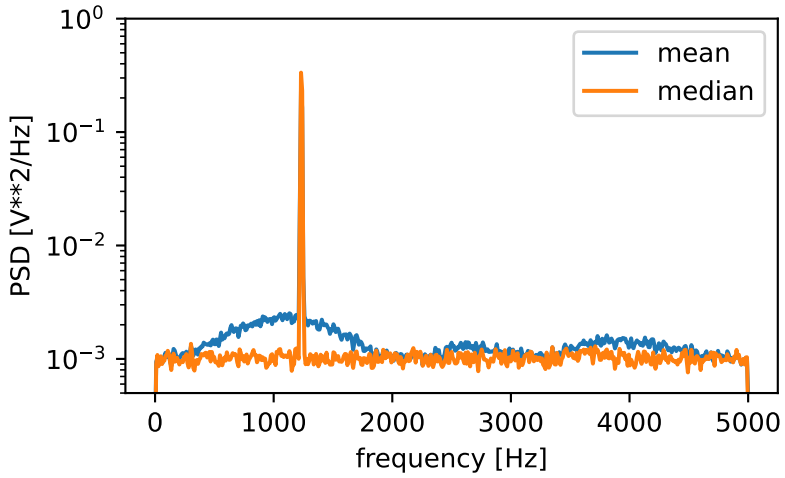


The peak height in the power spectrum is an estimate of the RMS amplitude.

```
>>> np.sqrt(Pxx_spec.max())
2.0077340678640727
```

If we now introduce a discontinuity in the signal, by increasing the amplitude of a small portion of the signal by 50, we can see the corruption of the mean average power spectral density, but using a median average better estimates the normal behaviour.

```
>>> x[int(N//2):int(N//2)+10] *= 50.
>>> f, Pxx_den = signal.welch(x, fs, nperseg=1024)
>>> f_med, Pxx_den_med = signal.welch(x, fs, nperseg=1024, average='median
↪')
>>> plt.semilogy(f, Pxx_den, label='mean')
>>> plt.semilogy(f_med, Pxx_den_med, label='median')
>>> plt.ylim([0.5e-3, 1])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.legend()
>>> plt.show()
```



scipy.signal.csd

scipy.signal.**csd**(*x*, *y*, *fs=1.0*, *window='hann'*, *nperseg=None*, *noverlap=None*, *nfft=None*, *detrend='constant'*, *return_onesided=True*, *scaling='density'*, *axis=- 1*, *average='mean'*)

Estimate the cross power spectral density, Pxy, using Welch's method.

Parameters

x [array_like] Time series of measurement values

y [array_like] Time series of measurement values

fs [float, optional] Sampling frequency of the *x* and *y* time series. Defaults to 1.0.

window [str or tuple or array_like, optional] Desired window to use. If *window* is a string or tuple, it is passed to *get_window* to generate the window values, which are DFT-even by default. See *get_window* for a list of windows and required parameters. If *window* is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.

nperseg [int, optional] Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.

noverlap: int, optional

Number of points to overlap between segments. If *None*, `noverlap = nperseg // 2`. Defaults to *None*.

nfft [int, optional] Length of the FFT used, if a zero padded FFT is desired. If *None*, the FFT length is *nperseg*. Defaults to *None*.

detrend [str or function or *False*, optional] Specifies how to detrend each segment. If `detrend` is a string, it is passed as the *type* argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is *False*, no detrending is done. Defaults to 'constant'.

return_onesided [bool, optional] If *True*, return a one-sided spectrum for real data. If *False* return a two-sided spectrum. Defaults to *True*, but for complex data, a two-sided spectrum is always returned.

scaling [{ 'density', 'spectrum' }, optional] Selects between computing the cross spectral density ('density') where *Pxy* has units of V**2/Hz and computing the cross spectrum ('spectrum') where *Pxy* has units of V**2, if *x* and *y* are measured in V and *fs* is measured in Hz. Defaults to 'density'

axis [int, optional] Axis along which the CSD is computed for both inputs; the default is over the last axis (i.e. `axis=-1`).

average [{ 'mean', 'median' }, optional] Method to use when averaging periodograms. If the spectrum is complex, the average is computed separately for the real and imaginary parts. Defaults to 'mean'.
New in version 1.2.0.

Returns

f [ndarray] Array of sample frequencies.

Pxy [ndarray] Cross spectral density or cross power spectrum of x,y.

See also:

periodogram

Simple, optionally modified periodogram

lombscargle

Lomb-Scargle periodogram for unevenly sampled data

welch

Power spectral density by Welch's method. [Equivalent to csd(x,x)]

coherence

Magnitude squared coherence by Welch's method.

Notes

By convention, Pxy is computed with the conjugate FFT of X multiplied by the FFT of Y.

If the input series differ in length, the shorter series will be zero-padded to match.

An appropriate amount of overlap will depend on the choice of window and on your requirements. For the default Hann window an overlap of 50% is a reasonable trade off between accurately estimating the signal power, while not over counting any of the data. Narrower windows may require a larger overlap.

New in version 0.16.0.

Examples

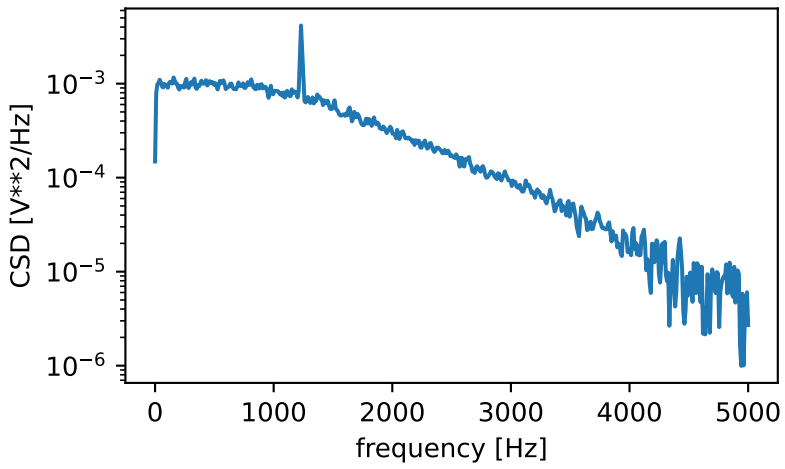
```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
```

Generate two test signals with some common features.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 20
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> b, a = signal.butter(2, 0.25, 'low')
>>> x = rng.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> y = signal.lfilter(b, a, x)
>>> x += amp*np.sin(2*np.pi*freq*time)
>>> y += rng.normal(scale=0.1*np.sqrt(noise_power), size=time.shape)
```

Compute and plot the magnitude of the cross spectral density.

```
>>> f, Pxy = signal.csd(x, y, fs, nperseg=1024)
>>> plt.semilogy(f, np.abs(Pxy))
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('CSD [V**2/Hz]')
>>> plt.show()
```



scipy.signal.coherence

scipy.signal.**coherence**(*x*, *y*, *fs=1.0*, *window='hann'*, *nperseg=None*, *noverlap=None*, *nfft=None*, *detrend='constant'*, *axis=- 1*)

Estimate the magnitude squared coherence estimate, Cxy, of discrete-time signals X and Y using Welch's method.

`Cxy = abs(Pxy)**2/(Pxx*Pyy)`, where *Pxx* and *Pyy* are power spectral density estimates of X and Y, and *Pxy* is the cross spectral density estimate of X and Y.

Parameters

x [array_like] Time series of measurement values

y [array_like] Time series of measurement values

fs [float, optional] Sampling frequency of the *x* and *y* time series. Defaults to 1.0.

window [str or tuple or array_like, optional] Desired window to use. If *window* is a string or tuple, it is passed to *get_window* to generate the window values, which are DFT-even by default. See *get_window* for a list of windows and required parameters. If *window* is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.

nperseg [int, optional] Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.

noverlap: int, optional
Number of points to overlap between segments. If *None*, `noverlap = nperseg // 2`. Defaults to *None*.

nfft [int, optional] Length of the FFT used, if a zero padded FFT is desired. If *None*, the FFT length is *nperseg*. Defaults to *None*.

detrend [str or function or *False*, optional] Specifies how to detrend each segment. If *detrend* is a string, it is passed as the *type* argument to the *detrend* function. If it is a function, it takes a segment and returns a detrended segment. If *detrend* is *False*, no detrending is done. Defaults to 'constant'.

axis [int, optional] Axis along which the coherence is computed for both inputs; the default is over the last axis (i.e. `axis=-1`).

Returns

f [ndarray] Array of sample frequencies.

Cxy [ndarray] Magnitude squared coherence of x and y.

>>> plt.ylabel('Coherence')
>>> plt.show()
```

scipy.signal.spectrogram

scipy.signal.**spectrogram**(*x*, *fs=1.0*, *window=('tukey', 0.25)*, *nperseg=None*, *noverlap=None*, *nfft=None*, *detrend='constant'*, *return_onesided=True*, *scaling='density'*, *axis=- 1*, *mode='psd'*)

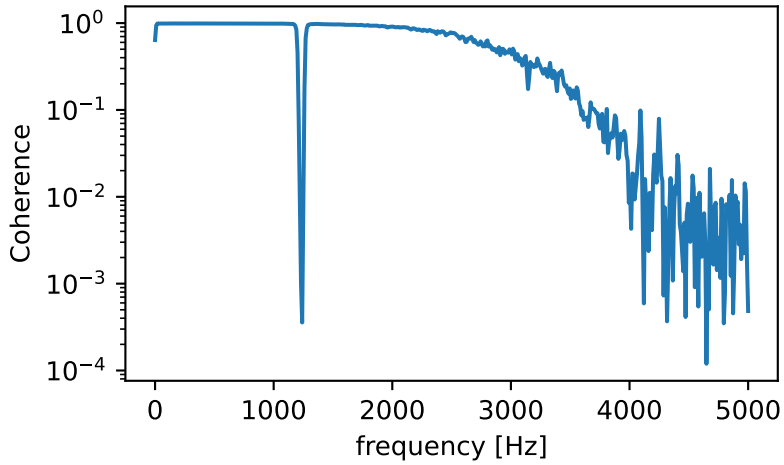
Compute a spectrogram with consecutive Fourier transforms.

Spectrograms can be used as a way of visualizing the change of a nonstationary signal's frequency content over time.

Parameters

x [array_like] Time series of measurement values

fs [float, optional] Sampling frequency of the *x* time series. Defaults to 1.0.



window [str or tuple or array_like, optional] Desired window to use. If *window* is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If *window* is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Tukey window with shape parameter of 0.25.

nperseg [int, optional] Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.

noverlap [int, optional] Number of points to overlap between segments. If *None*, `noverlap = nperseg // 8`. Defaults to *None*.

nfft [int, optional] Length of the FFT used, if a zero padded FFT is desired. If *None*, the FFT length is *nperseg*. Defaults to *None*.

detrend [str or function or *False*, optional] Specifies how to detrend each segment. If `detrend` is a string, it is passed as the *type* argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is *False*, no detrending is done. Defaults to 'constant'.

return_onesided [bool, optional] If *True*, return a one-sided spectrum for real data. If *False* return a two-sided spectrum. Defaults to *True*, but for complex data, a two-sided spectrum is always returned.

scaling [{ 'density', 'spectrum' }, optional] Selects between computing the power spectral density ('density') where *Sxx* has units of V**2/Hz and computing the power spectrum ('spectrum') where *Sxx* has units of V**2, if *x* is measured in V and *fs* is measured in Hz. Defaults to 'density'.

axis [int, optional] Axis along which the spectrogram is computed; the default is over the last axis (i.e. `axis=-1`).

mode [str, optional] Defines what kind of return values are expected. Options are ['psd', 'complex', 'magnitude', 'angle', 'phase']. 'complex' is equivalent to the output of `stft` with no padding or boundary extension. 'magnitude' returns the absolute magnitude of the STFT. 'angle' and 'phase' return the complex angle of the STFT, with and without unwrapping, respectively.

Returns

f [ndarray] Array of sample frequencies.

t [ndarray] Array of segment times.

Sxx [ndarray] Spectrogram of x. By default, the last axis of Sxx corresponds to the segment times.

See also:

periodogram

Simple, optionally modified periodogram

lombscargle

Lomb-Scargle periodogram for unevenly sampled data

welch

Power spectral density by Welch's method.

csd

Cross spectral density by Welch's method.

Notes

An appropriate amount of overlap will depend on the choice of window and on your requirements. In contrast to welch's method, where the entire data stream is averaged over, one may wish to use a smaller overlap (or perhaps none at all) when computing a spectrogram, to maintain some statistical independence between individual segments. It is for this reason that the default window is a Tukey window with 1/8th of a window's length overlap at each end.

New in version 0.16.0.

References

[1]

Examples

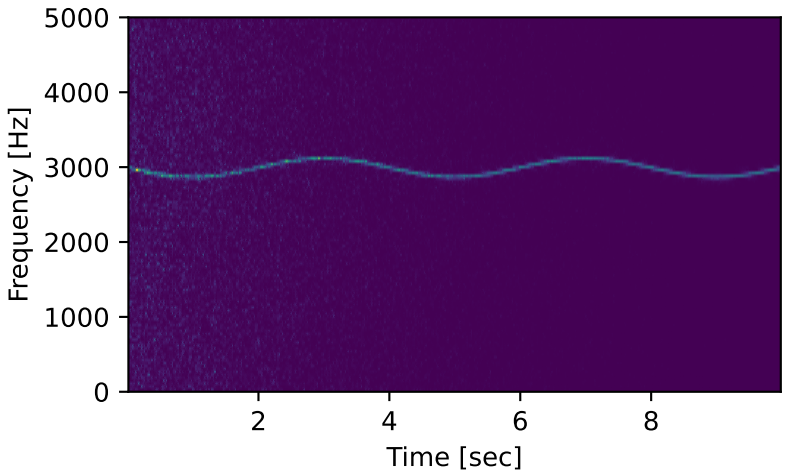
```
>>> from scipy import signal
>>> from scipy.fft import fftshift
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
```

Generate a test signal, a 2 Vrms sine wave whose frequency is slowly modulated around 3kHz, corrupted by white noise of exponentially decreasing magnitude sampled at 10 kHz.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.01 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> mod = 500*np.cos(2*np.pi*0.25*time)
>>> carrier = amp * np.sin(2*np.pi*3e3*time + mod)
>>> noise = rng.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> noise *= np.exp(-time/5)
>>> x = carrier + noise
```

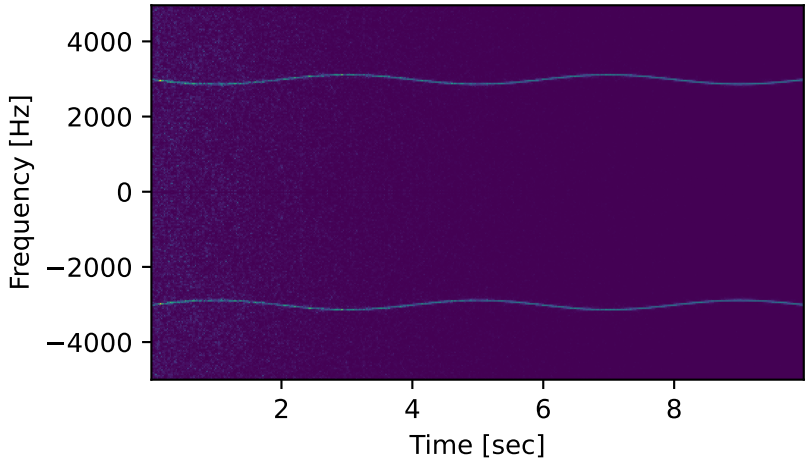
Compute and plot the spectrogram.

```
>>> f, t, Sxx = signal.spectrogram(x, fs)
>>> plt.pcolormesh(t, f, Sxx, shading='gouraud')
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
```



Note, if using output that is not one sided, then use the following:

```
>>> f, t, Sxx = signal.spectrogram(x, fs, return_onesided=False)
>>> plt.pcolormesh(t, fftshift(f), fftshift(Sxx, axes=0), shading='gouraud
↪')
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
```



scipy.signal.lombscargle

scipy.signal.**lombscargle**(*x*, *y*, *freqs*)

Computes the Lomb-Scargle periodogram.

The Lomb-Scargle periodogram was developed by Lomb [1] and further extended by Scargle [2] to find, and test the significance of weak periodic signals with uneven temporal sampling.

When *normalize* is False (default) the computed periodogram is unnormalized, it takes the value `(A**2) * N/4` for a harmonic signal with amplitude A for sufficiently large N.

When *normalize* is True the computed periodogram is normalized by the residuals of the data around a constant reference model (at zero).

Input arrays should be 1-D and will be cast to float64.

Parameters

x	[array_like] Sample times.
y	[array_like] Measurement values.
freqs	[array_like] Angular frequencies for output periodogram.
precenter	[bool, optional] Pre-center measurement values by subtracting the mean.
normalize	[bool, optional] Compute normalized periodogram.

Returns

pgram	[array_like] Lomb-Scargle periodogram.

Raises

ValueError
: If the input arrays *x* and *y* do not have the same shape.

See also:

istft

Inverse Short Time Fourier Transform

check_COLA

Check whether the Constant OverLap Add (COLA) constraint is met

welch

Power spectral density by Welch's method

spectrogram

Spectrogram by Welch's method

csd

Cross spectral density by Welch's method

Notes

This subroutine calculates the periodogram using a slightly modified algorithm due to Townsend [3] which allows the periodogram to be calculated using only a single pass through the input arrays for each frequency.

The algorithm running time scales roughly as O(x * freqs) or O(N^2) for a large number of samples and frequencies.

References

[1], [2], [3]

Examples

```
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
```

First define some input parameters for the signal:

```
>>> A = 2.
>>> w = 1.
>>> phi = 0.5 * np.pi
>>> nin = 1000
>>> nout = 100000
>>> frac_points = 0.9  # Fraction of points to select
```

Randomly select a fraction of an array with timesteps:

```
>>> r = rng.standard_normal(nin)
>>> x = np.linspace(0.01, 10*np.pi, nin)
>>> x = x[r >= frac_points]
```

Plot a sine wave for the selected times:

```
>>> y = A * np.sin(w*x+phi)
```

Define the array of frequencies for which to compute the periodogram:

```
>>> f = np.linspace(0.01, 10, nout)
```

Calculate Lomb-Scargle periodogram:

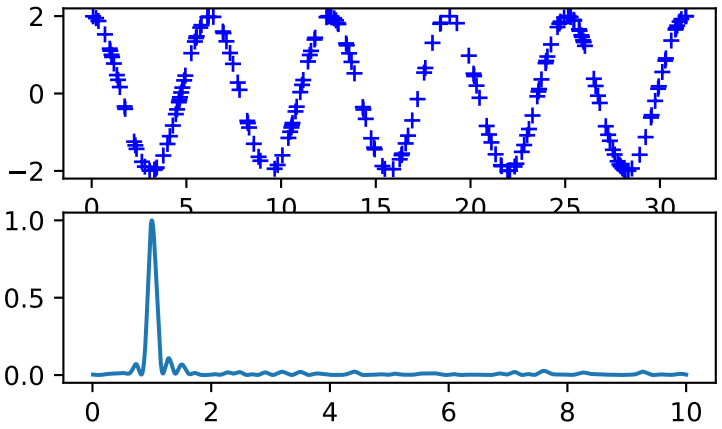
```
>>> import scipy.signal as signal
>>> pgram = signal.lombscargle(x, y, f, normalize=True)
```

Now make a plot of the input data:

```
>>> plt.subplot(2, 1, 1)
>>> plt.plot(x, y, 'b+')
```

Then plot the normalized periodogram:

```
>>> plt.subplot(2, 1, 2)
>>> plt.plot(f, pgram)
>>> plt.show()
```



scipy.signal.vectorstrength

scipy.signal.**vectorstrength**(*events*, *period*)

Determine the vector strength of the events corresponding to the given period.

The vector strength is a measure of phase synchrony, how well the timing of the events is synchronized to a single period of a periodic signal.

If multiple periods are used, calculate the vector strength of each. This is called the "resonating vector strength".

Parameters

events [1D array_like] An array of time points containing the timing of the events.

period [float or array_like] The period of the signal that the events should synchronize to. The period is in the same units as *events*. It can also be an array of periods, in which case the outputs are arrays of the same length.

Returns

strength [float or 1D array] The strength of the synchronization. 1.0 is perfect synchronization and 0.0 is no synchronization. If *period* is an array, this is also an array with each element containing the vector strength at the corresponding period.

phase [float or array] The phase that the events are most strongly synchronized to in radians. If *period* is an array, this is also an array with each element containing the phase for the corresponding period.

scipy.signal.stft

scipy.signal.**stft**(*x*, *fs=1.0*, *window='hann'*, *nperseg=256*, *noverlap=None*, *nfft=None*, *detrend=False*, *return_onesided=True*, *boundary='zeros'*, *padded=True*, *axis=- 1*)

Compute the Short Time Fourier Transform (STFT).

STFTs can be used as a way of quantifying the change of a nonstationary signal's frequency and phase content over time.

Parameters

x [array_like] Time series of measurement values

fs [float, optional] Sampling frequency of the *x* time series. Defaults to 1.0.

window [str or tuple or array_like, optional] Desired window to use. If *window* is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If *window* is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.

nperseg [int, optional] Length of each segment. Defaults to 256.

noverlap [int, optional] Number of points to overlap between segments. If *None*, `noverlap = nperseg // 2`. Defaults to *None*. When specified, the COLA constraint must be met (see Notes below).

nfft [int, optional] Length of the FFT used, if a zero padded FFT is desired. If *None*, the FFT length is *nperseg*. Defaults to *None*.

detrend [str or function or *False*, optional] Specifies how to detrend each segment. If `detrend` is a string, it is passed as the *type* argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is *False*, no detrending is done. Defaults to *False*.

return_onesided [bool, optional] If *True*, return a one-sided spectrum for real data. If *False* return a two-sided spectrum. Defaults to *True*, but for complex data, a two-sided spectrum is always returned.

boundary [str or None, optional] Specifies whether the input signal is extended at both ends, and how to generate the new values, in order to center the first windowed segment on the first input point. This has the benefit of enabling reconstruction of the first input point when the employed window function starts at zero. Valid options are `['even', 'odd', 'constant', 'zeros', None]`. Defaults to 'zeros', for zero padding extension. I.e. `[1, 2, 3, 4]` is extended to `[0, 1, 2, 3, 4, 0]` for `nperseg=3`.

padded [bool, optional] Specifies whether the input signal is zero-padded at the end to make the signal fit exactly into an integer number of window segments, so that all of the signal is included in the output. Defaults to *True*. Padding occurs after boundary extension, if *boundary* is not *None*, and *padded* is *True*, as is the default.

axis [int, optional] Axis along which the STFT is computed; the default is over the last axis (i.e. `axis=-1`).

Returns

f [ndarray] Array of sample frequencies.

t [ndarray] Array of segment times.

Zxx [ndarray] STFT of *x*. By default, the last axis of *Zxx* corresponds to the segment times.

lombscargle

Lomb-Scargle periodogram for unevenly sampled data

Notes

In order to enable inversion of an STFT via the inverse STFT in *istft*, the signal windowing must obey the constraint of "Nonzero OverLap Add" (NOLA), and the input signal must have complete windowing coverage (i.e. `(x.shape[axis] - nperseg) % (nperseg-noverlap) == 0`). The *padded* argument may be used to accomplish this.

Given a time-domain signal $x[n]$, a window $w[n]$, and a hop size H = *nperseg - noverlap*, the windowed frame at time index t is given by

$$x_t[n] = x[n]w[n - tH]$$

The overlap-add (OLA) reconstruction equation is given by

$$x[n] = \frac{\sum_t x_t[n]w[n - tH]}{\sum_t w^2[n - tH]}$$

The NOLA constraint ensures that every normalization term that appears in the denomimator of the OLA reconstruction equation is nonzero. Whether a choice of *window*, *nperseg*, and *noverlap* satisfy this constraint can be tested with *check_NOLA*.

New in version 0.19.0.

[1], [2]

Examples

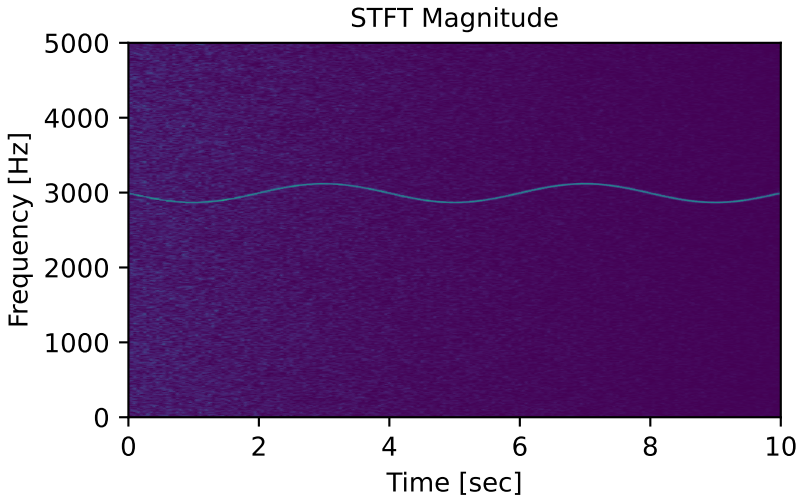
```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
```

Generate a test signal, a 2 Vrms sine wave whose frequency is slowly modulated around 3kHz, corrupted by white noise of exponentially decreasing magnitude sampled at 10 kHz.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.01 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> mod = 500*np.cos(2*np.pi*0.25*time)
>>> carrier = amp * np.sin(2*np.pi*3e3*time + mod)
>>> noise = rng.normal(scale=np.sqrt(noise_power),
...                    size=time.shape)
>>> noise *= np.exp(-time/5)
>>> x = carrier + noise
```

Compute and plot the STFT's magnitude.

```
>>> f, t, Zxx = signal.stft(x, fs, nperseg=1000)
>>> plt.pcolormesh(t, f, np.abs(Zxx), vmin=0, vmax=amp, shading='gouraud')
>>> plt.title('STFT Magnitude')
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
```



scipy.signal.istft

scipy.signal.**istft**(*Zxx*, *fs=1.0*, *window='hann'*, *nperseg=None*, *noverlap=None*, *nfft=None*, *input_onesided=True*, *boundary=True*, *time_axis=-1*, *freq_axis=-2*)

Perform the inverse Short Time Fourier transform (iSTFT).

Parameters

Zxx [array_like] STFT of the signal to be reconstructed. If a purely real array is passed, it will be cast to a complex data type.

fs [float, optional] Sampling frequency of the time series. Defaults to 1.0.

window [str or tuple or array_like, optional] Desired window to use. If *window* is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If *window* is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window. Must match the window used to generate the STFT for faithful inversion.

nperseg [int, optional] Number of data points corresponding to each STFT segment. This parameter must be specified if the number of data points per segment is odd, or if the STFT was padded via `nfft > nperseg`. If *None*, the value depends on the shape of *Zxx* and *input_onesided*. If *input_onesided* is *True*, `nperseg=2*(Zxx.shape[freq_axis] - 1)`. Otherwise, `nperseg=Zxx.shape[freq_axis]`. Defaults to *None*.

noverlap [int, optional] Number of points to overlap between segments. If *None*, half of the segment length. Defaults to *None*. When specified, the COLA constraint must be met (see Notes below), and should match the parameter used to generate the STFT. Defaults to *None*.

nfft [int, optional] Number of FFT points corresponding to each STFT segment. This parameter must be specified if the STFT was padded via `nfft > nperseg`. If *None*, the default values are the same as for *nperseg*, detailed above, with one exception: if *input_onesided* is True and `nperseg==2*Zxx.shape[freq_axis] - 1`, *nfft* also takes on that value. This case allows the proper inversion of an odd-length unpadded STFT using `nfft=None`. Defaults to *None*.

input_onesided [bool, optional] If *True*, interpret the input array as one-sided FFTs, such as is returned by `stft` with `return_onesided=True` and `numpy.fft.rfft`. If *False*, interpret the input as a a two-sided FFT. Defaults to *True*.

boundary [bool, optional] Specifies whether the input signal was extended at its boundaries by supplying a non-*None* `boundary` argument to `stft`. Defaults to *True*.

time_axis [int, optional] Where the time segments of the STFT is located; the default is the last axis (i.e. `axis=-1`).

freq_axis [int, optional] Where the frequency axis of the STFT is located; the default is the penultimate axis (i.e. `axis=-2`).

Returns

t [ndarray] Array of output data times.

x [ndarray] iSTFT of *Zxx*.

stft

Short Time Fourier Transform

check_COLA

Check whether the Constant OverLap Add (COLA) constraint is met

check_NOLA

Check whether the Nonzero Overlap Add (NOLA) constraint is met

Notes

In order to enable inversion of an STFT via the inverse STFT with *istft*, the signal windowing must obey the constraint of "nonzero overlap add" (NOLA):

$$\sum_t w^2[n - tH] \neq 0$$

This ensures that the normalization factors that appear in the denominator of the overlap-add reconstruction equation

$$x[n] = \frac{\sum_t x_t[n] w[n - tH]}{\sum_t w^2[n - tH]}$$

are not zero. The NOLA constraint can be checked with the *check_NOLA* function.

An STFT which has been modified (via masking or otherwise) is not guaranteed to correspond to a exactly realizible signal. This function implements the iSTFT via the least-squares estimation algorithm detailed in [2], which produces a signal that minimizes the mean squared error between the STFT of the returned signal and the modified STFT.

New in version 0.19.0.

References

[1], [2]

Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
```

Generate a test signal, a 2 Vrms sine wave at 50Hz corrupted by 0.001 V**2/Hz of white noise sampled at 1024 Hz.

```
>>> fs = 1024
>>> N = 10*fs
>>> nperseg = 512
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> carrier = amp * np.sin(2*np.pi*50*time)
>>> noise = rng.normal(scale=np.sqrt(noise_power),
...                    size=time.shape)
>>> x = carrier + noise
```

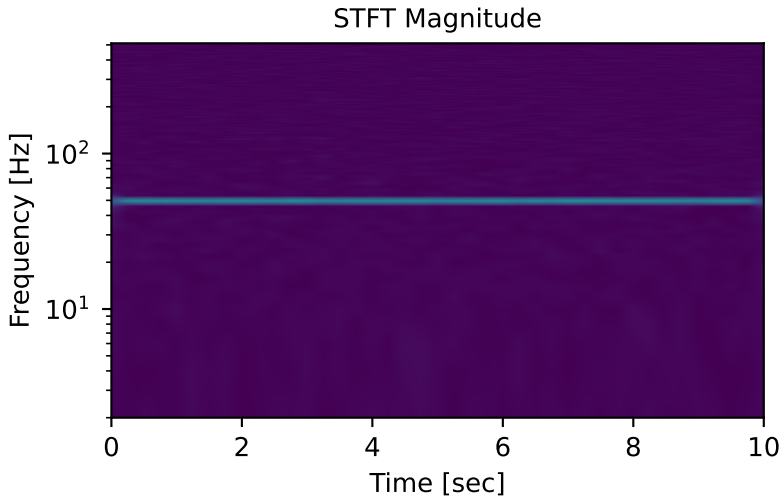
Compute the STFT, and plot its magnitude

```
>>> f, t, Zxx = signal.stft(x, fs=fs, nperseg=nperseg)
>>> plt.figure()
>>> plt.pcolormesh(t, f, np.abs(Zxx), vmin=0, vmax=amp, shading='gouraud')
>>> plt.ylim([f[1], f[-1]])
>>> plt.title('STFT Magnitude')
```

(continues on next page)

(continued from previous page)

```
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.yscale('log')
>>> plt.show()
```



Zero the components that are 10% or less of the carrier magnitude, then convert back to a time series via inverse STFT

```
>>> Zxx = np.where(np.abs(Zxx) >= amp/10, Zxx, 0)
>>> _, xrec = signal.istft(Zxx, fs)
```

Compare the cleaned signal with the original and true carrier signals.

```
>>> plt.figure()
>>> plt.plot(time, x, time, xrec, time, carrier)
>>> plt.xlim([2, 2.1])
>>> plt.xlabel('Time [sec]')
>>> plt.ylabel('Signal')
>>> plt.legend(['Carrier + Noise', 'Filtered via STFT', 'True Carrier'])
>>> plt.show()
```

Note that the cleaned signal does not start as abruptly as the original, since some of the coefficients of the transient were also removed:

```
>>> plt.figure()
>>> plt.plot(time, x, time, xrec, time, carrier)
>>> plt.xlim([0, 0.1])
>>> plt.xlabel('Time [sec]')
>>> plt.ylabel('Signal')
>>> plt.legend(['Carrier + Noise', 'Filtered via STFT', 'True Carrier'])
>>> plt.show()
```

scipy.signal.check_COLA

scipy.signal.**check_COLA**(*window*, *nperseg*, *noverlap*, *tol=1e-10*)

Check whether the Constant OverLap Add (COLA) constraint is met.

Parameters

window [str or tuple or array_like] Desired window to use. If *window* is a string or tuple, it is passed to *get_window* to generate the window values, which are DFT-even by default. See *get_window* for a list of windows and required parameters. If *window* is array_like it will be used directly as the window and its length must be nperseg.

nperseg [int] Length of each segment.

noverlap [int] Number of points to overlap between segments.

tol [float, optional] The allowed variance of a bin's weighted sum from the median bin sum.

Returns

verdict [bool] *True* if chosen combination satisfies COLA within *tol*, *False* otherwise

See also:

check_NOLA

Check whether the Nonzero Overlap Add (NOLA) constraint is met

stft

Short Time Fourier Transform

istft

Inverse Short Time Fourier Transform

Notes

In order to enable inversion of an STFT via the inverse STFT in *istft*, it is sufficient that the signal windowing obeys the constraint of "Constant OverLap Add" (COLA). This ensures that every point in the input data is equally weighted, thereby avoiding aliasing and allowing full reconstruction.

Some examples of windows that satisfy COLA:

- Rectangular window at overlap of 0, 1/2, 2/3, 3/4, …
- Bartlett window at overlap of 1/2, 3/4, 5/6, …
- Hann window at 1/2, 2/3, 3/4, …
- Any Blackman family window at 2/3 overlap
- Any window with `noverlap = nperseg-1`

A very comprehensive list of other windows may be found in [2], wherein the COLA condition is satisfied when the "Amplitude Flatness" is unity.

New in version 0.19.0.

References

[1], [2]

Examples

```
>>> from scipy import signal
```

Confirm COLA condition for rectangular window of 75% (3/4) overlap:

```
>>> signal.check_COLA(signal.windows.boxcar(100), 100, 75)
True
```

COLA is not true for 25% (1/4) overlap, though:

```
>>> signal.check_COLA(signal.windows.boxcar(100), 100, 25)
False
```

"Symmetrical" Hann window (for filter design) is not COLA:

```
>>> signal.check_COLA(signal.windows.hann(120, sym=True), 120, 60)
False
```

"Periodic" or "DFT-even" Hann window (for FFT analysis) is COLA for overlap of 1/2, 2/3, 3/4, etc.:

```
>>> signal.check_COLA(signal.windows.hann(120, sym=False), 120, 60)
True
```

```
>>> signal.check_COLA(signal.windows.hann(120, sym=False), 120, 80)
True
```

```
>>> signal.check_COLA(signal.windows.hann(120, sym=False), 120, 90)
True
```

scipy.signal.check_NOLA

scipy.signal.**check_NOLA**(*window*, *nperseg*, *noverlap*, *tol=1e-10*)

Check whether the Nonzero Overlap Add (NOLA) constraint is met.

Parameters

window [str or tuple or array_like] Desired window to use. If *window* is a string or tuple, it is passed to *get_window* to generate the window values, which are DFT-even by default. See *get_window* for a list of windows and required parameters. If *window* is array_like it will be used directly as the window and its length must be nperseg.

nperseg [int] Length of each segment.

noverlap [int] Number of points to overlap between segments.

tol [float, optional] The allowed variance of a bin's weighted sum from the median bin sum.

Returns

verdict [bool] *True* if chosen combination satisfies the NOLA constraint within *tol*, *False* otherwise

See also:

check_COLA

Check whether the Constant OverLap Add (COLA) constraint is met

stft

Short Time Fourier Transform

istft

Inverse Short Time Fourier Transform

Notes

In order to enable inversion of an STFT via the inverse STFT in *istft*, the signal windowing must obey the constraint of "nonzero overlap add" (NOLA):

$$\sum_{t} w^2[n - tH] \neq 0$$

for all n, where w is the window function, t is the frame index, and H is the hop size (H = *nperseg* - *noverlap*).

This ensures that the normalization factors in the denominator of the overlap-add inversion equation are not zero. Only very pathological windows will fail the NOLA constraint.

New in version 1.2.0.

References

[1], [2]

Examples

```
>>> from scipy import signal
```

Confirm NOLA condition for rectangular window of 75% (3/4) overlap:

```
>>> signal.check_NOLA(signal.windows.boxcar(100), 100, 75)
True
```

NOLA is also true for 25% (1/4) overlap:

```
>>> signal.check_NOLA(signal.windows.boxcar(100), 100, 25)
True
```

"Symmetrical" Hann window (for filter design) is also NOLA:

```
>>> signal.check_NOLA(signal.windows.hann(120, sym=True), 120, 60)
True
```

As long as there is overlap, it takes quite a pathological window to fail NOLA:

```
>>> w = np.ones(64, dtype="float")
>>> w[::2] = 0
>>> signal.check_NOLA(w, 64, 32)
False
```

If there is not enough overlap, a window with zeros at the ends will not work:

```
>>> signal.check_NOLA(signal.windows.hann(64), 64, 0)
False
>>> signal.check_NOLA(signal.windows.hann(64), 64, 1)
False
>>> signal.check_NOLA(signal.windows.hann(64), 64, 2)
True
```

3.3.23 Sparse matrices (`scipy.sparse`)

SciPy 2-D sparse matrix package for numeric data.

Contents

Sparse matrix classes

bsr_matrix(arg1[, shape, dtype, copy, blocksize])	Block Sparse Row matrix
coo_matrix(arg1[, shape, dtype, copy])	A sparse matrix in COOrdinate format.
csc_matrix(arg1[, shape, dtype, copy])	Compressed Sparse Column matrix
csr_matrix(arg1[, shape, dtype, copy])	Compressed Sparse Row matrix
dia_matrix(arg1[, shape, dtype, copy])	Sparse matrix with DIAgonal storage
dok_matrix(arg1[, shape, dtype, copy])	Dictionary Of Keys based sparse matrix.
lil_matrix(arg1[, shape, dtype, copy])	Row-based list of lists sparse matrix
spmatrix([maxprint])	This class provides a base class for all sparse matrices.

scipy.sparse.bsr_matrix

class scipy.sparse.**bsr_matrix**(*arg1*, *shape=None*, *dtype=None*, *copy=False*, *blocksize=None*)

Block Sparse Row matrix

This can be instantiated in several ways:

bsr_matrix(D, [blocksize=(R,C)])

where D is a dense matrix or 2-D ndarray.

bsr_matrix(S, [blocksize=(R,C)])

with another sparse matrix S (equivalent to S.tobsr())

bsr_matrix((M, N), [blocksize=(R,C), dtype])

to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

bsr_matrix((data, ij), [blocksize=(R,C), shape=(M, N)])

where `data` and `ij` satisfy `a[ij[0, k], ij[1, k]] = data[k]`

bsr_matrix((data, indices, indptr), [shape=(M, N)])

is the standard BSR representation where the block column indices for row i are stored in `indices[indptr[i]:indptr[i+1]]` and their corresponding block values are stored in `data[ indptr[i]: indptr[i+1] ]`. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Summary of BSR format

The Block Compressed Row (BSR) format is very similar to the Compressed Sparse Row (CSR) format. BSR is appropriate for sparse matrices with dense sub matrices like the last example below. Block matrices often arise in vector-valued finite element discretizations. In such cases, BSR is considerably more efficient than CSR and CSC for many sparse arithmetic operations.

Blocksize

The blocksize (R,C) must evenly divide the shape of the matrix (M,N). That is, R and C must satisfy the relationship `M % R = 0` and `N % C = 0`.

If no blocksize is specified, a simple heuristic is applied to determine an appropriate blocksize.

Examples

```
>>> from scipy.sparse import bsr_matrix
>>> bsr_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```
>>> row = np.array([0, 0, 1, 2, 2, 2])
>>> col = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3 ,4, 5, 6])
>>> bsr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])
```

```
>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6]).repeat(4).reshape(6, 2, 2)
>>> bsr_matrix((data,indices,indptr), shape=(6, 6)).toarray()
array([[1, 1, 0, 0, 2, 2],
       [1, 1, 0, 0, 2, 2],
       [0, 0, 0, 0, 3, 3],
       [0, 0, 0, 0, 3, 3],
       [4, 4, 5, 5, 6, 6],
       [4, 4, 5, 5, 6, 6]])
```

Attributes

dtype	[dtype] Data type of the matrix
shape	[2-tuple] Get shape of a matrix.
ndim	[int] Number of dimensions (this is always 2)
nnz	Number of stored values, including explicit zeros.
data	Data array of the matrix
indices	BSR format index array
indptr	BSR format index pointer array

blocksize Block size of the matrix

has_sorted_indices
Determine whether the matrix has sorted indices

Methods

__len__()	
__mul__(other)	interpret other and call one of the following
arcsin()	Element-wise arcsin.
arcsinh()	Element-wise arcsinh.
arctan()	Element-wise arctan.
arctanh()	Element-wise arctanh.
argmax([axis, out])	Return indices of maximum elements along an axis.
argmin([axis, out])	Return indices of minimum elements along an axis.
asformat(format[, copy])	Return this matrix in the passed format.
asfptype()	Upcast matrix to a floating point format (if necessary)
astype(dtype[, casting, copy])	Cast the matrix elements to a specified type.
ceil()	Element-wise ceil.
check_format([full_check])	check whether the matrix format is valid
conj([copy])	Element-wise complex conjugation.
conjugate([copy])	Element-wise complex conjugation.
copy()	Returns a copy of this matrix.
count_nonzero()	Number of non-zero entries, equivalent to
deg2rad()	Element-wise deg2rad.
diagonal([k])	Returns the kth diagonal of the matrix.
dot(other)	Ordinary dot product
eliminate_zeros()	Remove zero elements in-place.
expm1()	Element-wise expm1.
floor()	Element-wise floor.
getH()	Return the Hermitian transpose of this matrix.
get_shape()	Get shape of a matrix.
getcol(j)	Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
getformat()	Format of a matrix representation as a string.
getmaxprint()	Maximum number of elements to display when printed.
getnnz([axis])	Number of stored values, including explicit zeros.
getrow(i)	Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
log1p()	Element-wise log1p.
matmat(**kwds)	matmat is deprecated! BSR matmat is deprecated in SciPy 0.19.0.
matvec(**kwds)	matvec is deprecated! BSR matvec is deprecated in SciPy 0.19.0.
max([axis, out])	Return the maximum of the matrix or maximum along an axis.
maximum(other)	Element-wise maximum between this and another matrix.
mean([axis, dtype, out])	Compute the arithmetic mean along the specified axis.

continues on next page

Table 175 – continued from previous page

min([axis, out])	Return the minimum of the matrix or maximum along an axis.
minimum(other)	Element-wise minimum between this and another matrix.
multiply(other)	Point-wise multiplication by another matrix, vector, or scalar.
nonzero()	nonzero indices
power(n[, dtype])	This function performs element-wise power.
prune()	Remove empty space after all non-zero elements.
rad2deg()	Element-wise rad2deg.
reshape(self, shape[, order, copy])	Gives a new shape to a sparse matrix without changing its data.
resize(*shape)	Resize the matrix in-place to dimensions given by `shape`
rint()	Element-wise rint.
set_shape(shape)	See *reshape*.
setdiag(values[, k])	Set diagonal or off-diagonal elements of the array.
sign()	Element-wise sign.
sin()	Element-wise sin.
sinh()	Element-wise sinh.
sort_indices()	Sort the indices of this matrix *in place*
sorted_indices()	Return a copy of this matrix with sorted indices
sqrt()	Element-wise sqrt.
sum([axis, dtype, out])	Sum the matrix elements over a given axis.
sum_duplicates()	Eliminate duplicate matrix entries by adding them together
tan()	Element-wise tan.
tanh()	Element-wise tanh.
toarray([order, out])	Return a dense ndarray representation of this matrix.
tobsr([blocksize, copy])	Convert this matrix into Block Sparse Row Format.
tocoo([copy])	Convert this matrix to COOrdinate format.
tocsc([copy])	Convert this matrix to Compressed Sparse Column format.
tocsr([copy])	Convert this matrix to Compressed Sparse Row format.
todense([order, out])	Return a dense matrix representation of this matrix.
todia([copy])	Convert this matrix to sparse DIAgonal format.
todok([copy])	Convert this matrix to Dictionary Of Keys format.
tolil([copy])	Convert this matrix to List of Lists format.
transpose([axes, copy])	Reverses the dimensions of the sparse matrix.
trunc()	Element-wise trunc.

scipy.sparse.bsr_matrix.__len__

bsr_matrix.**__len__**()

scipy.sparse.bsr_matrix.__mul__

bsr_matrix.**__mul__**(*other*)
interpret other and call one of the following

self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

scipy.sparse.bsr_matrix.arcsin

bsr_matrix.**arcsin**()
Element-wise arcsin.

See numpy.arcsin for more information.

scipy.sparse.bsr_matrix.arcsinh

bsr_matrix.**arcsinh**()
Element-wise arcsinh.

See numpy.arcsinh for more information.

scipy.sparse.bsr_matrix.arctan

bsr_matrix.**arctan**()
Element-wise arctan.

See numpy.arctan for more information.

scipy.sparse.bsr_matrix.arctanh

bsr_matrix.**arctanh**()
Element-wise arctanh.

See numpy.arctanh for more information.

scipy.sparse.bsr_matrix.argmax

bsr_matrix.**argmax**(*axis=None*, *out=None*)
Return indices of maximum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

Parameters

axis [{-2, -1, 0, 1, None}, optional] Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

ind [numpy.matrix or int] Indices of maximum elements. If matrix, its size along *axis* is 1.

scipy.sparse.bsr_matrix.argmin

bsr_matrix.**argmin**(*axis=None*, *out=None*)

Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

Parameters

axis [{-2, -1, 0, 1, None}, optional] Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

ind [numpy.matrix or int] Indices of minimum elements. If matrix, its size along *axis* is 1.

scipy.sparse.bsr_matrix.asformat

bsr_matrix.**asformat**(*format*, *copy=False*)

Return this matrix in the passed format.

Parameters

format [{str, None}] The desired matrix format ("csr", "csc", "lil", "dok", "array", …) or None for no conversion.

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [This matrix in the passed format.]

scipy.sparse.bsr_matrix.asfptype

bsr_matrix.**asfptype**()

Upcast matrix to a floating point format (if necessary)

scipy.sparse.bsr_matrix.astype

bsr_matrix.**astype**(*dtype*, *casting='unsafe'*, *copy=True*)

Cast the matrix elements to a specified type.

Parameters

dtype [string or numpy dtype] Typecode or data-type to which to cast the data.

casting [{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.

copy [bool, optional] If *copy* is *False*, the result might share some memory with this matrix. If *copy* is *True*, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.bsr_matrix.ceil

bsr_matrix.**ceil**()

Element-wise ceil.

See numpy.ceil for more information.

scipy.sparse.bsr_matrix.check_format

bsr_matrix.**check_format**(*full_check=True*)

check whether the matrix format is valid

Parameters*:*

full_check:

True - rigorous check, O(N) operations : default False - basic check, O(1) operations

scipy.sparse.bsr_matrix.conj

bsr_matrix.**conj**(*copy=True*)

Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.bsr_matrix.conjugate

bsr_matrix.**conjugate**(*copy=True*)

Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.bsr_matrix.copy

bsr_matrix.**copy**()

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

scipy.sparse.bsr_matrix.count_nonzero

bsr_matrix.**count_nonzero**()

Number of non-zero entries, equivalent to

np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.bsr_matrix.deg2rad

bsr_matrix.**deg2rad**()

Element-wise deg2rad.

See numpy.deg2rad for more information.

scipy.sparse.bsr_matrix.diagonal

bsr_matrix.**diagonal**(*k=0*)

Returns the kth diagonal of the matrix.

Parameters

k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
New in version 1.0.

See also:

numpy.diagonal

Equivalent numpy function.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.bsr_matrix.dot

bsr_matrix.**dot**(*other*)
Ordinary dot product

Examples

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.bsr_matrix.eliminate_zeros

bsr_matrix.**eliminate_zeros**()
Remove zero elements in-place.

scipy.sparse.bsr_matrix.expm1

bsr_matrix.**expm1**()
Element-wise expm1.

See numpy.expm1 for more information.

scipy.sparse.bsr_matrix.floor

bsr_matrix.**floor**()
Element-wise floor.

See numpy.floor for more information.

scipy.sparse.bsr_matrix.getH

bsr_matrix.**getH**()
Return the Hermitian transpose of this matrix.

See also:

numpy.matrix.getH

NumPy's implementation of *getH* for matrices

scipy.sparse.bsr_matrix.get_shape

bsr_matrix.**get_shape**()
Get shape of a matrix.

scipy.sparse.bsr_matrix.getcol

bsr_matrix.**getcol**(*j*)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.bsr_matrix.getformat

bsr_matrix.**getformat**()
Format of a matrix representation as a string.

scipy.sparse.bsr_matrix.getmaxprint

bsr_matrix.**getmaxprint**()
Maximum number of elements to display when printed.

scipy.sparse.bsr_matrix.getnnz

bsr_matrix.**getnnz**(*axis=None*)
Number of stored values, including explicit zeros.

Parameters

axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:

count_nonzero

Number of non-zero entries

scipy.sparse.bsr_matrix.getrow

bsr_matrix.**getrow**(*i*)
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.bsr_matrix.log1p

bsr_matrix.**log1p**()
Element-wise log1p.

See numpy.log1p for more information.

scipy.sparse.bsr_matrix.matmat

bsr_matrix.**matmat**(***kwds*)
matmat is deprecated! BSR matmat is deprecated in SciPy 0.19.0. Use * operator instead.

Multiply this sparse matrix by other matrix.

scipy.sparse.bsr_matrix.matvec

bsr_matrix.**matvec**(***kwds*)
matvec is deprecated! BSR matvec is deprecated in SciPy 0.19.0. Use * operator instead.

Multiply matrix by vector.

scipy.sparse.bsr_matrix.max

bsr_matrix.**max**(*axis=None*, *out=None*)
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e., *axis* = *None*).

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amax [coo_matrix or scalar] Maximum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a sparse.coo_matrix of dimension `a.ndim - 1`.

See also:

min

The minimum value of a sparse matrix along a given axis.

numpy.matrix.max

NumPy's implementation of 'max' for matrices

scipy.sparse.bsr_matrix.maximum

bsr_matrix.**maximum**(*other*)
Element-wise maximum between this and another matrix.

scipy.sparse.bsr_matrix.mean

bsr_matrix.**mean**(*axis=None*, *dtype=None*, *out=None*)
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., *axis* = *None*).

dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

m [np.matrix]

See also:

numpy.matrix.mean

NumPy's implementation of 'mean' for matrices

scipy.sparse.bsr_matrix.min

bsr_matrix.**min**(*axis=None*, *out=None*)
Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e., *axis* = *None*).

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amin [coo_matrix or scalar] Minimum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a sparse.coo_matrix of dimension `a.ndim - 1`.

See also:

max

The maximum value of a sparse matrix along a given axis.

numpy.matrix.min

NumPy's implementation of 'min' for matrices

scipy.sparse.bsr_matrix.minimum

bsr_matrix.**minimum**(*other*)
Element-wise minimum between this and another matrix.

scipy.sparse.bsr_matrix.multiply

bsr_matrix.**multiply**(*other*)
Point-wise multiplication by another matrix, vector, or scalar.

scipy.sparse.bsr_matrix.nonzero

bsr_matrix.**nonzero**()
nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.bsr_matrix.power

bsr_matrix.**power**(*n*, *dtype=None*)
This function performs element-wise power.

Parameters

n	[n is a scalar]
dtype	[If dtype is not specified, the current dtype will be preserved.]

scipy.sparse.bsr_matrix.prune

bsr_matrix.**prune**()
Remove empty space after all non-zero elements.

scipy.sparse.bsr_matrix.rad2deg

bsr_matrix.**rad2deg**()
Element-wise rad2deg.

See numpy.rad2deg for more information.

scipy.sparse.bsr_matrix.reshape

bsr_matrix.**reshape**(*self*, *shape*, *order='C'*, *copy=False*)
Gives a new shape to a sparse matrix without changing its data.

Parameters

shape [length-2 tuple of ints] The new shape should be compatible with the original shape.
order [{'C', 'F'}, optional] Read the elements using this index order. 'C' means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. 'F' means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

reshaped_matrix
[sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

numpy.matrix.reshape

NumPy's implementation of 'reshape' for matrices

scipy.sparse.bsr_matrix.resize

bsr_matrix.**resize**(**shape*)
Resize the matrix in-place to dimensions given by shape

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

shape [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

scipy.sparse.bsr_matrix.rint

bsr_matrix.**rint**()
Element-wise rint.

See `numpy.rint` for more information.

scipy.sparse.bsr_matrix.set_shape

bsr_matrix.**set_shape**(*shape*)
See *reshape*.

scipy.sparse.bsr_matrix.setdiag

bsr_matrix.**setdiag**(*values*, *k=0*)
Set diagonal or off-diagonal elements of the array.

Parameters

values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

scipy.sparse.bsr_matrix.sign

bsr_matrix.**sign**()
Element-wise sign.

See `numpy.sign` for more information.

scipy.sparse.bsr_matrix.sin

bsr_matrix.**sin**()
Element-wise sin.

See numpy.sin for more information.

scipy.sparse.bsr_matrix.sinh

bsr_matrix.**sinh**()
Element-wise sinh.

See numpy.sinh for more information.

scipy.sparse.bsr_matrix.sort_indices

bsr_matrix.**sort_indices**()
Sort the indices of this matrix *in place*

scipy.sparse.bsr_matrix.sorted_indices

bsr_matrix.**sorted_indices**()
Return a copy of this matrix with sorted indices

scipy.sparse.bsr_matrix.sqrt

bsr_matrix.**sqrt**()
Element-wise sqrt.

See numpy.sqrt for more information.

scipy.sparse.bsr_matrix.sum

bsr_matrix.**sum**(*axis=None*, *dtype=None*, *out=None*)
Sum the matrix elements over a given axis.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., *axis* = *None*).

dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

sum_along_axis
[np.matrix] A matrix with the same shape as *self*, with the specified axis removed.

See also:

numpy.matrix.sum

NumPy's implementation of 'sum' for matrices

scipy.sparse.bsr_matrix.sum_duplicates

bsr_matrix.**sum_duplicates**()
Eliminate duplicate matrix entries by adding them together

The is an *in place* operation

scipy.sparse.bsr_matrix.tan

bsr_matrix.**tan**()
Element-wise tan.

See numpy.tan for more information.

scipy.sparse.bsr_matrix.tanh

bsr_matrix.**tanh**()
Element-wise tanh.

See numpy.tanh for more information.

scipy.sparse.bsr_matrix.toarray

bsr_matrix.**toarray**(*order=None*, *out=None*)
Return a dense ndarray representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

Returns

arr [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.bsr_matrix.tobsr

bsr_matrix.**tobsr**(*blocksize=None*, *copy=False*)
Convert this matrix into Block Sparse Row Format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

If blocksize=(R, C) is provided, it will be used for determining block size of the bsr_matrix.

scipy.sparse.bsr_matrix.tocoo

bsr_matrix.**tocoo**(*copy=True*)
Convert this matrix to COOrdinate format.

When copy=False the data array will be shared between this matrix and the resultant coo_matrix.

scipy.sparse.bsr_matrix.tocsc

bsr_matrix.**tocsc**(*copy=False*)
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.bsr_matrix.tocsr

bsr_matrix.**tocsr**(*copy=False*)
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.bsr_matrix.todense

bsr_matrix.**todense**(*order=None*, *out=None*)
Return a dense matrix representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out [ndarray, 2-D, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

scipy.sparse.bsr_matrix.todia

bsr_matrix.**todia**(*copy=False*)
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.bsr_matrix.todok

bsr_matrix.**todok**(*copy=False*)
Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.bsr_matrix.tolil

bsr_matrix.**tolil**(*copy=False*)
Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.bsr_matrix.transpose

bsr_matrix.**transpose**(*axes=None*, *copy=False*)
Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

copy [bool, optional] Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [*self* with the dimensions reversed.]

See also:

numpy.matrix.transpose

NumPy's implementation of 'transpose' for matrices

scipy.sparse.bsr_matrix.trunc

bsr_matrix.**trunc**()
Element-wise trunc.

See numpy.trunc for more information.

__getitem__	

scipy.sparse.coo_matrix

class scipy.sparse.**coo_matrix**(*arg1*, *shape=None*, *dtype=None*, *copy=False*)

A sparse matrix in COOrdinate format.

Also known as the 'ijv' or 'triplet' format.

This can be instantiated in several ways:

coo_matrix(D)

with a dense matrix D

coo_matrix(S)

with another sparse matrix S (equivalent to S.tocoo())

coo_matrix((M, N), [dtype])

to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

coo_matrix((data, (i, j)), [shape=(M, N)])

to construct from three arrays:

1. data[:] the entries of the matrix, in any order
2. i[:] the row indices of the matrix entries
3. j[:] the column indices of the matrix entries

Where `A[i[k], j[k]] = data[k]`. When shape is not specified, it is inferred from the index arrays

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Advantages of the COO format

- facilitates fast conversion among sparse formats
- permits duplicate entries (see example)
- very fast conversion to and from CSR/CSC formats

Disadvantages of the COO format

- **does not directly support:**
  - arithmetic operations
  - slicing

Intended Usage

- COO is a fast format for constructing sparse matrices

- Once a matrix has been constructed, convert to CSR or CSC format for fast arithmetic and matrix vector operations
- By default when converting to CSR or CSC format, duplicate (i,j) entries will be summed together. This facilitates efficient construction of finite element matrices and the like. (see example)

Examples

```
>>> # Constructing an empty matrix
>>> from scipy.sparse import coo_matrix
>>> coo_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```
>>> # Constructing a matrix using ijv format
>>> row  = np.array([0, 3, 1, 0])
>>> col  = np.array([0, 3, 1, 2])
>>> data = np.array([4, 5, 7, 9])
>>> coo_matrix((data, (row, col)), shape=(4, 4)).toarray()
array([[4, 0, 9, 0],
       [0, 7, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 5]])
```

```
>>> # Constructing a matrix with duplicate indices
>>> row  = np.array([0, 0, 1, 3, 1, 0, 0])
>>> col  = np.array([0, 2, 1, 3, 1, 0, 0])
>>> data = np.array([1, 1, 1, 1, 1, 1, 1])
>>> coo = coo_matrix((data, (row, col)), shape=(4, 4))
>>> # Duplicate indices are maintained until implicitly or explicitly␣
 ↪summed
>>> np.max(coo.data)
1
>>> coo.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

Attributes

dtype	[dtype] Data type of the matrix
shape	[2-tuple] Get shape of a matrix.
ndim	[int] Number of dimensions (this is always 2)
nnz	Number of stored values, including explicit zeros.
data	COO format data array of the matrix
row	COO format row index array of the matrix
col	COO format column index array of the matrix

Methods

__len__()	

__mul__(other)	interpret other and call one of the following
arcsin()	Element-wise arcsin.
arcsinh()	Element-wise arcsinh.
arctan()	Element-wise arctan.
arctanh()	Element-wise arctanh.
argmax([axis, out])	Return indices of maximum elements along an axis.
argmin([axis, out])	Return indices of minimum elements along an axis.
asformat(format[, copy])	Return this matrix in the passed format.
asfptype()	Upcast matrix to a floating point format (if necessary)
astype(dtype[, casting, copy])	Cast the matrix elements to a specified type.
ceil()	Element-wise ceil.
conj([copy])	Element-wise complex conjugation.
conjugate([copy])	Element-wise complex conjugation.
copy()	Returns a copy of this matrix.
count_nonzero()	Number of non-zero entries, equivalent to
deg2rad()	Element-wise deg2rad.
diagonal([k])	Returns the kth diagonal of the matrix.
dot(other)	Ordinary dot product
eliminate_zeros()	Remove zero entries from the matrix
expm1()	Element-wise expm1.
floor()	Element-wise floor.
getH()	Return the Hermitian transpose of this matrix.
get_shape()	Get shape of a matrix.
getcol(j)	Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
getformat()	Format of a matrix representation as a string.
getmaxprint()	Maximum number of elements to display when printed.
getnnz([axis])	Number of stored values, including explicit zeros.
getrow(i)	Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
log1p()	Element-wise log1p.
max([axis, out])	Return the maximum of the matrix or maximum along an axis.
maximum(other)	Element-wise maximum between this and another matrix.
mean([axis, dtype, out])	Compute the arithmetic mean along the specified axis.
min([axis, out])	Return the minimum of the matrix or maximum along an axis.
minimum(other)	Element-wise minimum between this and another matrix.
multiply(other)	Point-wise multiplication by another matrix
nonzero()	nonzero indices
power(n[, dtype])	This function performs element-wise power.
rad2deg()	Element-wise rad2deg.
reshape(self, shape[, order, copy])	Gives a new shape to a sparse matrix without changing its data.

continues on next page

Table 176 – continued from previous page

resize(*shape)	Resize the matrix in-place to dimensions given by `shape`
rint()	Element-wise rint.
set_shape(shape)	See *reshape*.
setdiag(values[, k])	Set diagonal or off-diagonal elements of the array.
sign()	Element-wise sign.
sin()	Element-wise sin.
sinh()	Element-wise sinh.
sqrt()	Element-wise sqrt.
sum([axis, dtype, out])	Sum the matrix elements over a given axis.
sum_duplicates()	Eliminate duplicate matrix entries by adding them together
tan()	Element-wise tan.
tanh()	Element-wise tanh.
toarray([order, out])	See the docstring for *spmatrix.toarray*.
tobsr([blocksize, copy])	Convert this matrix to Block Sparse Row format.
tocoo([copy])	Convert this matrix to COOrdinate format.
tocsc([copy])	Convert this matrix to Compressed Sparse Column format
tocsr([copy])	Convert this matrix to Compressed Sparse Row format
todense([order, out])	Return a dense matrix representation of this matrix.
todia([copy])	Convert this matrix to sparse DIAgonal format.
todok([copy])	Convert this matrix to Dictionary Of Keys format.
tolil([copy])	Convert this matrix to List of Lists format.
transpose([axes, copy])	Reverses the dimensions of the sparse matrix.
trunc()	Element-wise trunc.

scipy.sparse.coo_matrix.__len__

coo_matrix.**__len__**()

scipy.sparse.coo_matrix.__mul__

coo_matrix.**__mul__**(*other*)

interpret other and call one of the following

self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

scipy.sparse.coo_matrix.arcsin

coo_matrix.**arcsin**()

Element-wise arcsin.

See `numpy.arcsin` for more information.

scipy.sparse.coo_matrix.arcsinh

coo_matrix.**arcsinh**()
Element-wise arcsinh.

See numpy.arcsinh for more information.

scipy.sparse.coo_matrix.arctan

coo_matrix.**arctan**()
Element-wise arctan.

See numpy.arctan for more information.

scipy.sparse.coo_matrix.arctanh

coo_matrix.**arctanh**()
Element-wise arctanh.

See numpy.arctanh for more information.

scipy.sparse.coo_matrix.argmax

coo_matrix.**argmax**(*axis=None*, *out=None*)
Return indices of maximum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

Parameters

axis [{-2, -1, 0, 1, None}, optional] Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

ind [numpy.matrix or int] Indices of maximum elements. If matrix, its size along *axis* is 1.

scipy.sparse.coo_matrix.argmin

coo_matrix.**argmin**(*axis=None*, *out=None*)
Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

Parameters

axis [{-2, -1, 0, 1, None}, optional] Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

ind [numpy.matrix or int] Indices of minimum elements. If matrix, its size along *axis* is 1.

scipy.sparse.coo_matrix.asformat

coo_matrix.**asformat**(*format*, *copy=False*)

Return this matrix in the passed format.

Parameters

format [{str, None}] The desired matrix format ("csr", "csc", "lil", "dok", "array", …) or None for no conversion.

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [This matrix in the passed format.]

scipy.sparse.coo_matrix.asfptype

coo_matrix.**asfptype**()

Upcast matrix to a floating point format (if necessary)

scipy.sparse.coo_matrix.astype

coo_matrix.**astype**(*dtype*, *casting='unsafe'*, *copy=True*)

Cast the matrix elements to a specified type.

Parameters

dtype [string or numpy dtype] Typecode or data-type to which to cast the data.

casting [{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.

copy [bool, optional] If *copy* is *False*, the result might share some memory with this matrix. If *copy* is *True*, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.coo_matrix.ceil

coo_matrix.**ceil**()

Element-wise ceil.

See numpy.ceil for more information.

scipy.sparse.coo_matrix.conj

coo_matrix.**conj**(*copy=True*)

Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.coo_matrix.conjugate

coo_matrix.**conjugate**(*copy=True*)

Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.coo_matrix.copy

coo_matrix.**copy**()

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

scipy.sparse.coo_matrix.count_nonzero

coo_matrix.**count_nonzero**()

Number of non-zero entries, equivalent to

np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.coo_matrix.deg2rad

coo_matrix.**deg2rad**()
Element-wise deg2rad.

See numpy.deg2rad for more information.

scipy.sparse.coo_matrix.diagonal

coo_matrix.**diagonal**(*k=0*)
Returns the kth diagonal of the matrix.

Parameters

k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
New in version 1.0.

See also:

numpy.diagonal

Equivalent numpy function.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.coo_matrix.dot

coo_matrix.**dot**(*other*)
Ordinary dot product

Examples

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.coo_matrix.eliminate_zeros

coo_matrix.**eliminate_zeros**()
Remove zero entries from the matrix

This is an *in place* operation

scipy.sparse.coo_matrix.expm1

coo_matrix.**expm1**()
Element-wise expm1.

See numpy.expm1 for more information.

scipy.sparse.coo_matrix.floor

coo_matrix.**floor**()
Element-wise floor.

See numpy.floor for more information.

scipy.sparse.coo_matrix.getH

coo_matrix.**getH**()
Return the Hermitian transpose of this matrix.

See also:

numpy.matrix.getH

NumPy's implementation of *getH* for matrices

scipy.sparse.coo_matrix.get_shape

coo_matrix.**get_shape**()
Get shape of a matrix.

scipy.sparse.coo_matrix.getcol

coo_matrix.**getcol**(*j*)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.coo_matrix.getformat

coo_matrix.**getformat**()
Format of a matrix representation as a string.

scipy.sparse.coo_matrix.getmaxprint

coo_matrix.**getmaxprint**()
Maximum number of elements to display when printed.

scipy.sparse.coo_matrix.getnnz

coo_matrix.**getnnz**(*axis=None*)
Number of stored values, including explicit zeros.

Parameters

axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:

count_nonzero

Number of non-zero entries

scipy.sparse.coo_matrix.getrow

coo_matrix.**getrow**(*i*)
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.coo_matrix.log1p

coo_matrix.**log1p**()
Element-wise log1p.

See numpy.log1p for more information.

scipy.sparse.coo_matrix.max

coo_matrix.**max**(*axis=None*, *out=None*)
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e., *axis* = *None*).

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amax [coo_matrix or scalar] Maximum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a sparse.coo_matrix of dimension `a.ndim - 1`.

See also:

`min`

The minimum value of a sparse matrix along a given axis.

`numpy.matrix.max`

NumPy's implementation of 'max' for matrices

scipy.sparse.coo_matrix.maximum

`coo_matrix.`**`maximum`**(*other*)

Element-wise maximum between this and another matrix.

scipy.sparse.coo_matrix.mean

`coo_matrix.`**`mean`**(*axis=None*, *dtype=None*, *out=None*)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., *axis* = *None*).

dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

m [np.matrix]

See also:

`numpy.matrix.mean`

NumPy's implementation of 'mean' for matrices

scipy.sparse.coo_matrix.min

coo_matrix.**min**(*axis=None*, *out=None*)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e., *axis* = *None*).

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amin [coo_matrix or scalar] Minimum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a sparse.coo_matrix of dimension `a.ndim - 1`.

See also:

max

The maximum value of a sparse matrix along a given axis.

numpy.matrix.min

NumPy's implementation of 'min' for matrices

scipy.sparse.coo_matrix.minimum

coo_matrix.**minimum**(*other*)

Element-wise minimum between this and another matrix.

scipy.sparse.coo_matrix.multiply

coo_matrix.**multiply**(*other*)

Point-wise multiplication by another matrix

scipy.sparse.coo_matrix.nonzero

coo_matrix.**nonzero**()

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.coo_matrix.power

coo_matrix.**power**(*n*, *dtype=None*)

This function performs element-wise power.

Parameters

n [n is a scalar]

dtype [If dtype is not specified, the current dtype will be preserved.]

scipy.sparse.coo_matrix.rad2deg

coo_matrix.**rad2deg**()

Element-wise rad2deg.

See numpy.rad2deg for more information.

scipy.sparse.coo_matrix.reshape

coo_matrix.**reshape**(*self*, *shape*, *order='C'*, *copy=False*)

Gives a new shape to a sparse matrix without changing its data.

Parameters

shape [length-2 tuple of ints] The new shape should be compatible with the original shape.

order [{'C', 'F'}, optional] Read the elements using this index order. 'C' means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. 'F' means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.

copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

reshaped_matrix

[sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

See also:

numpy.matrix.reshape

NumPy's implementation of 'reshape' for matrices

scipy.sparse.coo_matrix.resize

coo_matrix.**resize**(**shape*)
Resize the matrix in-place to dimensions given by `shape`

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

shape [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

scipy.sparse.coo_matrix.rint

coo_matrix.**rint**()
Element-wise rint.

See `numpy.rint` for more information.

scipy.sparse.coo_matrix.set_shape

coo_matrix.**set_shape**(*shape*)
See *reshape*.

scipy.sparse.coo_matrix.setdiag

coo_matrix.**setdiag**(*values*, *k=0*)
Set diagonal or off-diagonal elements of the array.

Parameters

values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

scipy.sparse.coo_matrix.sign

coo_matrix.**sign**()
Element-wise sign.

See numpy.sign for more information.

scipy.sparse.coo_matrix.sin

coo_matrix.**sin**()
Element-wise sin.

See numpy.sin for more information.

scipy.sparse.coo_matrix.sinh

coo_matrix.**sinh**()
Element-wise sinh.

See numpy.sinh for more information.

scipy.sparse.coo_matrix.sqrt

coo_matrix.**sqrt**()
Element-wise sqrt.

See numpy.sqrt for more information.

scipy.sparse.coo_matrix.sum

coo_matrix.**sum**(*axis=None*, *dtype=None*, *out=None*)
Sum the matrix elements over a given axis.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., *axis* = *None*).

dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

sum_along_axis
[np.matrix] A matrix with the same shape as *self*, with the specified axis removed.

See also:

numpy.matrix.sum

NumPy's implementation of 'sum' for matrices

scipy.sparse.coo_matrix.sum_duplicates

coo_matrix.**sum_duplicates**()
Eliminate duplicate matrix entries by adding them together

This is an *in place* operation

scipy.sparse.coo_matrix.tan

coo_matrix.**tan**()
Element-wise tan.

See numpy.tan for more information.

scipy.sparse.coo_matrix.tanh

coo_matrix.**tanh**()
Element-wise tanh.

See numpy.tanh for more information.

scipy.sparse.coo_matrix.toarray

coo_matrix.**toarray**(*order=None*, *out=None*)
See the docstring for *spmatrix.toarray*.

scipy.sparse.coo_matrix.tobsr

coo_matrix.**tobsr**(*blocksize=None*, *copy=False*)
Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

scipy.sparse.coo_matrix.tocoo

coo_matrix.**tocoo**(*copy=False*)
Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.coo_matrix.tocsc

coo_matrix.**tocsc**(*copy=False*)

Convert this matrix to Compressed Sparse Column format

Duplicate entries will be summed together.

Examples

```
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row  = array([0, 0, 1, 3, 1, 0, 0])
>>> col  = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsc()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

scipy.sparse.coo_matrix.tocsr

coo_matrix.**tocsr**(*copy=False*)

Convert this matrix to Compressed Sparse Row format

Duplicate entries will be summed together.

Examples

```
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row  = array([0, 0, 1, 3, 1, 0, 0])
>>> col  = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsr()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

scipy.sparse.coo_matrix.todense

coo_matrix.**todense**(*order=None*, *out=None*)

Return a dense matrix representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out [ndarray, 2-D, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

scipy.sparse.coo_matrix.todia

coo_matrix.**todia**(*copy=False*)

Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.coo_matrix.todok

coo_matrix.**todok**(*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.coo_matrix.tolil

coo_matrix.**tolil**(*copy=False*)

Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.coo_matrix.transpose

coo_matrix.**transpose**(*axes=None*, *copy=False*)

Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

copy [bool, optional] Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [*self* with the dimensions reversed.]

See also:

numpy.matrix.transpose

NumPy's implementation of 'transpose' for matrices

scipy.sparse.coo_matrix.trunc

coo_matrix.**trunc**()
Element-wise trunc.

See numpy.trunc for more information.

scipy.sparse.csc_matrix

class scipy.sparse.**csc_matrix**(*arg1*, *shape=None*, *dtype=None*, *copy=False*)
Compressed Sparse Column matrix

This can be instantiated in several ways:

csc_matrix(D)
with a dense matrix or rank-2 ndarray D
csc_matrix(S)
with another sparse matrix S (equivalent to S.tocsc())
csc_matrix((M, N), [dtype])
to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.
csc_matrix((data, (row_ind, col_ind)), [shape=(M, N)])
where `data`, `row_ind` and `col_ind` satisfy the relationship `a[row_ind[k], col_ind[k]] = data[k]`.
csc_matrix((data, indices, indptr), [shape=(M, N)])
is the standard CSC representation where the row indices for column i are stored in `indices[indptr[i]:indptr[i+1]]` and their corresponding values are stored in `data[indptr[i]:indptr[i+1]]`. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Advantages of the CSC format

- efficient arithmetic operations CSC + CSC, CSC * CSC, etc.
- efficient column slicing
- fast matrix vector products (CSR, BSR may be faster)

Disadvantages of the CSC format

- slow row slicing operations (consider CSR)
- changes to the sparsity structure are expensive (consider LIL or DOK)

Examples

```
>>> import numpy as np
>>> from scipy.sparse import csc_matrix
>>> csc_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```
>>> row = np.array([0, 2, 2, 0, 1, 2])
>>> col = np.array([0, 0, 1, 2, 2, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csc_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 4],
       [0, 0, 5],
       [2, 3, 6]])
```

```
>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csc_matrix((data, indices, indptr), shape=(3, 3)).toarray()
array([[1, 0, 4],
       [0, 0, 5],
       [2, 3, 6]])
```

Attributes

dtype	[dtype] Data type of the matrix
shape	[2-tuple] Get shape of a matrix.
ndim	[int] Number of dimensions (this is always 2)
nnz	Number of stored values, including explicit zeros.
data	Data array of the matrix
indices	CSC format index array
indptr	CSC format index pointer array
has_sorted_indices	Determine whether the matrix has sorted indices

Methods

`__len__`()	

`__mul__`(other)	interpret other and call one of the following
`arcsin`()	Element-wise arcsin.
`arcsinh`()	Element-wise arcsinh.
`arctan`()	Element-wise arctan.
`arctanh`()	Element-wise arctanh.
`argmax`([axis, out])	Return indices of maximum elements along an axis.
`argmin`([axis, out])	Return indices of minimum elements along an axis.
`asformat`(format[, copy])	Return this matrix in the passed format.
`asfptype`()	Upcast matrix to a floating point format (if necessary)
`astype`(dtype[, casting, copy])	Cast the matrix elements to a specified type.
`ceil`()	Element-wise ceil.
`check_format`([full_check])	check whether the matrix format is valid
`conj`([copy])	Element-wise complex conjugation.
`conjugate`([copy])	Element-wise complex conjugation.
`copy`()	Returns a copy of this matrix.
`count_nonzero`()	Number of non-zero entries, equivalent to
`deg2rad`()	Element-wise deg2rad.
`diagonal`([k])	Returns the kth diagonal of the matrix.
`dot`(other)	Ordinary dot product
`eliminate_zeros`()	Remove zero entries from the matrix
`expm1`()	Element-wise expm1.
`floor`()	Element-wise floor.
`getH`()	Return the Hermitian transpose of this matrix.
`get_shape`()	Get shape of a matrix.
`getcol`(i)	Returns a copy of column i of the matrix, as a (m x 1) CSC matrix (column vector).
`getformat`()	Format of a matrix representation as a string.
`getmaxprint`()	Maximum number of elements to display when printed.
`getnnz`([axis])	Number of stored values, including explicit zeros.
`getrow`(i)	Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
`log1p`()	Element-wise log1p.
`max`([axis, out])	Return the maximum of the matrix or maximum along an axis.
`maximum`(other)	Element-wise maximum between this and another matrix.
`mean`([axis, dtype, out])	Compute the arithmetic mean along the specified axis.
`min`([axis, out])	Return the minimum of the matrix or maximum along an axis.
`minimum`(other)	Element-wise minimum between this and another matrix.
`multiply`(other)	Point-wise multiplication by another matrix, vector, or scalar.
`nonzero`()	nonzero indices
`power`(n[, dtype])	This function performs element-wise power.
`prune`()	Remove empty space after all non-zero elements.

continues on next page

Table 177 – continued from previous page

rad2deg()	Element-wise rad2deg.
reshape(self, shape[, order, copy])	Gives a new shape to a sparse matrix without changing its data.
resize(*shape)	Resize the matrix in-place to dimensions given by `shape`
rint()	Element-wise rint.
set_shape(shape)	See *reshape*.
setdiag(values[, k])	Set diagonal or off-diagonal elements of the array.
sign()	Element-wise sign.
sin()	Element-wise sin.
sinh()	Element-wise sinh.
sort_indices()	Sort the indices of this matrix *in place*
sorted_indices()	Return a copy of this matrix with sorted indices
sqrt()	Element-wise sqrt.
sum([axis, dtype, out])	Sum the matrix elements over a given axis.
sum_duplicates()	Eliminate duplicate matrix entries by adding them together
tan()	Element-wise tan.
tanh()	Element-wise tanh.
toarray([order, out])	Return a dense ndarray representation of this matrix.
tobsr([blocksize, copy])	Convert this matrix to Block Sparse Row format.
tocoo([copy])	Convert this matrix to COOrdinate format.
tocsc([copy])	Convert this matrix to Compressed Sparse Column format.
tocsr([copy])	Convert this matrix to Compressed Sparse Row format.
todense([order, out])	Return a dense matrix representation of this matrix.
todia([copy])	Convert this matrix to sparse DIAgonal format.
todok([copy])	Convert this matrix to Dictionary Of Keys format.
tolil([copy])	Convert this matrix to List of Lists format.
transpose([axes, copy])	Reverses the dimensions of the sparse matrix.
trunc()	Element-wise trunc.

scipy.sparse.csc_matrix.__len__

csc_matrix.**__len__**()

scipy.sparse.csc_matrix.__mul__

csc_matrix.**__mul__**(*other*)
interpret other and call one of the following

self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

scipy.sparse.csc_matrix.arcsin

csc_matrix.**arcsin**()
Element-wise arcsin.

See numpy.arcsin for more information.

scipy.sparse.csc_matrix.arcsinh

csc_matrix.**arcsinh**()
Element-wise arcsinh.

See numpy.arcsinh for more information.

scipy.sparse.csc_matrix.arctan

csc_matrix.**arctan**()
Element-wise arctan.

See numpy.arctan for more information.

scipy.sparse.csc_matrix.arctanh

csc_matrix.**arctanh**()
Element-wise arctanh.

See numpy.arctanh for more information.

scipy.sparse.csc_matrix.argmax

csc_matrix.**argmax**(*axis=None*, *out=None*)
Return indices of maximum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

Parameters

axis [{-2, -1, 0, 1, None}, optional] Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

ind [numpy.matrix or int] Indices of maximum elements. If matrix, its size along *axis* is 1.

scipy.sparse.csc_matrix.argmin

csc_matrix.**argmin**(*axis=None*, *out=None*)

Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

Parameters

axis [{-2, -1, 0, 1, None}, optional] Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

ind [numpy.matrix or int] Indices of minimum elements. If matrix, its size along *axis* is 1.

scipy.sparse.csc_matrix.asformat

csc_matrix.**asformat**(*format*, *copy=False*)

Return this matrix in the passed format.

Parameters

format [{str, None}] The desired matrix format ("csr", "csc", "lil", "dok", "array", ...) or None for no conversion.

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [This matrix in the passed format.]

scipy.sparse.csc_matrix.asfptype

csc_matrix.**asfptype**()

Upcast matrix to a floating point format (if necessary)

scipy.sparse.csc_matrix.astype

csc_matrix.**astype**(*dtype*, *casting='unsafe'*, *copy=True*)

Cast the matrix elements to a specified type.

Parameters

dtype [string or numpy dtype] Typecode or data-type to which to cast the data.

casting [{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.

copy [bool, optional] If *copy* is *False*, the result might share some memory with this matrix. If *copy* is *True*, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.csc_matrix.ceil

csc_matrix.**ceil**()
Element-wise ceil.

See numpy.ceil for more information.

scipy.sparse.csc_matrix.check_format

csc_matrix.**check_format**(*full_check=True*)
check whether the matrix format is valid

Parameters

full_check [bool, optional] If *True*, rigorous check, O(N) operations. Otherwise basic check, O(1) operations (default True).

scipy.sparse.csc_matrix.conj

csc_matrix.**conj**(*copy=True*)
Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.csc_matrix.conjugate

csc_matrix.**conjugate**(*copy=True*)
Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.csc_matrix.copy

csc_matrix.**copy**()
Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

scipy.sparse.csc_matrix.count_nonzero

csc_matrix.**count_nonzero**()
Number of non-zero entries, equivalent to

np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.csc_matrix.deg2rad

csc_matrix.**deg2rad**()
Element-wise deg2rad.

See numpy.deg2rad for more information.

scipy.sparse.csc_matrix.diagonal

csc_matrix.**diagonal**(*k=0*)
Returns the kth diagonal of the matrix.

Parameters

k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
New in version 1.0.

See also:

numpy.diagonal

Equivalent numpy function.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.csc_matrix.dot

csc_matrix.**dot**(*other*)
Ordinary dot product

Examples

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.csc_matrix.eliminate_zeros

csc_matrix.**eliminate_zeros**()
Remove zero entries from the matrix

This is an *in place* operation.

scipy.sparse.csc_matrix.expm1

csc_matrix.**expm1**()
Element-wise expm1.

See numpy.expm1 for more information.

scipy.sparse.csc_matrix.floor

csc_matrix.**floor**()
Element-wise floor.

See numpy.floor for more information.

scipy.sparse.csc_matrix.getH

csc_matrix.**getH**()
Return the Hermitian transpose of this matrix.

See also:

numpy.matrix.getH

NumPy's implementation of *getH* for matrices

scipy.sparse.csc_matrix.get_shape

csc_matrix.**get_shape**()
Get shape of a matrix.

scipy.sparse.csc_matrix.getcol

csc_matrix.**getcol**(*i*)
Returns a copy of column i of the matrix, as a (m x 1) CSC matrix (column vector).

scipy.sparse.csc_matrix.getformat

csc_matrix.**getformat**()
Format of a matrix representation as a string.

scipy.sparse.csc_matrix.getmaxprint

csc_matrix.**getmaxprint**()
Maximum number of elements to display when printed.

scipy.sparse.csc_matrix.getnnz

csc_matrix.**getnnz**(*axis=None*)
Number of stored values, including explicit zeros.

Parameters

axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:

count_nonzero

Number of non-zero entries

scipy.sparse.csc_matrix.getrow

csc_matrix.**getrow**(*i*)
Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).

scipy.sparse.csc_matrix.log1p

csc_matrix.**log1p**()
Element-wise log1p.

See numpy.log1p for more information.

scipy.sparse.csc_matrix.max

csc_matrix.**max**(*axis=None*, *out=None*)
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e., *axis* = *None*).

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amax [coo_matrix or scalar] Maximum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a sparse.coo_matrix of dimension `a.ndim - 1`.

See also:

min

The minimum value of a sparse matrix along a given axis.

numpy.matrix.max

NumPy's implementation of 'max' for matrices

scipy.sparse.csc_matrix.maximum

csc_matrix.**maximum**(*other*)
Element-wise maximum between this and another matrix.

scipy.sparse.csc_matrix.mean

csc_matrix.**mean**(*axis=None*, *dtype=None*, *out=None*)
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., *axis* = *None*).

dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

m [np.matrix]

See also:

numpy.matrix.mean

NumPy's implementation of 'mean' for matrices

scipy.sparse.csc_matrix.min

csc_matrix.**min**(*axis=None*, *out=None*)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e., *axis* = *None*).

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amin [coo_matrix or scalar] Minimum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a sparse.coo_matrix of dimension `a.ndim - 1`.

See also:

max

The maximum value of a sparse matrix along a given axis.

numpy.matrix.min

NumPy's implementation of 'min' for matrices

scipy.sparse.csc_matrix.minimum

csc_matrix.**minimum**(*other*)

Element-wise minimum between this and another matrix.

scipy.sparse.csc_matrix.multiply

csc_matrix.**multiply**(*other*)
Point-wise multiplication by another matrix, vector, or scalar.

scipy.sparse.csc_matrix.nonzero

csc_matrix.**nonzero**()
nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.csc_matrix.power

csc_matrix.**power**(*n*, *dtype=None*)
This function performs element-wise power.

Parameters

n	[n is a scalar]
dtype	[If dtype is not specified, the current dtype will be preserved.]

scipy.sparse.csc_matrix.prune

csc_matrix.**prune**()
Remove empty space after all non-zero elements.

scipy.sparse.csc_matrix.rad2deg

csc_matrix.**rad2deg**()
Element-wise rad2deg.

See numpy.rad2deg for more information.

scipy.sparse.csc_matrix.reshape

csc_matrix.**reshape**(*self*, *shape*, *order='C'*, *copy=False*)

Gives a new shape to a sparse matrix without changing its data.

Parameters

shape [length-2 tuple of ints] The new shape should be compatible with the original shape.

order [{'C', 'F'}, optional] Read the elements using this index order. 'C' means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. 'F' means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.

copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

reshaped_matrix

[sparse matrix] A sparse matrix with the given `shape`, not necessarily of the same format as the current object.

See also:

numpy.matrix.reshape

NumPy's implementation of 'reshape' for matrices

scipy.sparse.csc_matrix.resize

csc_matrix.**resize**(**shape*)

Resize the matrix in-place to dimensions given by `shape`

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

shape [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

scipy.sparse.csc_matrix.rint

csc_matrix.**rint**()
Element-wise rint.

See numpy.rint for more information.

scipy.sparse.csc_matrix.set_shape

csc_matrix.**set_shape**(*shape*)
See *reshape*.

scipy.sparse.csc_matrix.setdiag

csc_matrix.**setdiag**(*values*, *k=0*)
Set diagonal or off-diagonal elements of the array.

Parameters

values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

scipy.sparse.csc_matrix.sign

csc_matrix.**sign**()
Element-wise sign.

See numpy.sign for more information.

scipy.sparse.csc_matrix.sin

csc_matrix.**sin**()
Element-wise sin.

See numpy.sin for more information.

scipy.sparse.csc_matrix.sinh

csc_matrix.**sinh**()
Element-wise sinh.

See numpy.sinh for more information.

scipy.sparse.csc_matrix.sort_indices

csc_matrix.**sort_indices**()
Sort the indices of this matrix *in place*

scipy.sparse.csc_matrix.sorted_indices

csc_matrix.**sorted_indices**()
Return a copy of this matrix with sorted indices

scipy.sparse.csc_matrix.sqrt

csc_matrix.**sqrt**()
Element-wise sqrt.

See numpy.sqrt for more information.

scipy.sparse.csc_matrix.sum

csc_matrix.**sum**(*axis=None*, *dtype=None*, *out=None*)
Sum the matrix elements over a given axis.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., *axis* = *None*).

dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

sum_along_axis
[np.matrix] A matrix with the same shape as *self*, with the specified axis removed.

See also:

numpy.matrix.sum

NumPy's implementation of 'sum' for matrices

scipy.sparse.csc_matrix.sum_duplicates

csc_matrix.**sum_duplicates**()
Eliminate duplicate matrix entries by adding them together

This is an *in place* operation.

scipy.sparse.csc_matrix.tan

csc_matrix.**tan**()
Element-wise tan.

See numpy.tan for more information.

scipy.sparse.csc_matrix.tanh

csc_matrix.**tanh**()
Element-wise tanh.

See numpy.tanh for more information.

scipy.sparse.csc_matrix.toarray

csc_matrix.**toarray**(*order=None*, *out=None*)
Return a dense ndarray representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

Returns

arr [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.csc_matrix.tobsr

csc_matrix.**tobsr**(*blocksize=None*, *copy=False*)
Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

scipy.sparse.csc_matrix.tocoo

csc_matrix.**tocoo**(*copy=True*)
Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.csc_matrix.tocsc

csc_matrix.**tocsc**(*copy=False*)
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.csc_matrix.tocsr

csc_matrix.**tocsr**(*copy=False*)
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.csc_matrix.todense

csc_matrix.**todense**(*order=None*, *out=None*)
Return a dense matrix representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out [ndarray, 2-D, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

scipy.sparse.csc_matrix.todia

csc_matrix.**todia**(*copy=False*)
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.csc_matrix.todok

csc_matrix.**todok**(*copy=False*)
Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.csc_matrix.tolil

csc_matrix.**tolil**(*copy=False*)
Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.csc_matrix.transpose

csc_matrix.**transpose**(*axes=None*, *copy=False*)
Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

copy [bool, optional] Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [*self* with the dimensions reversed.]

See also:

numpy.matrix.transpose

NumPy's implementation of 'transpose' for matrices

scipy.sparse.csc_matrix.trunc

csc_matrix.**trunc**()
Element-wise trunc.

See numpy.trunc for more information.

__getitem__	

scipy.sparse.csr_matrix

class scipy.sparse.**csr_matrix**(*arg1*, *shape=None*, *dtype=None*, *copy=False*)

Compressed Sparse Row matrix

This can be instantiated in several ways:

csr_matrix(D)

with a dense matrix or rank-2 ndarray D

csr_matrix(S)

with another sparse matrix S (equivalent to S.tocsr())

csr_matrix((M, N), [dtype])

to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

csr_matrix((data, (row_ind, col_ind)), [shape=(M, N)])

where `data`, `row_ind` and `col_ind` satisfy the relationship `a[row_ind[k], col_ind[k]] = data[k]`.

csr_matrix((data, indices, indptr), [shape=(M, N)])

is the standard CSR representation where the column indices for row i are stored in `indices[indptr[i]:indptr[i+1]]` and their corresponding values are stored in `data[indptr[i]:indptr[i+1]]`. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Advantages of the CSR format

- efficient arithmetic operations CSR + CSR, CSR * CSR, etc.
- efficient row slicing
- fast matrix vector products

Disadvantages of the CSR format

- slow column slicing operations (consider CSC)
- changes to the sparsity structure are expensive (consider LIL or DOK)

Examples

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> csr_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```
>>> row = np.array([0, 0, 1, 2, 2, 2])
>>> col = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])
```

```
>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csr_matrix((data, indices, indptr), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])
```

Duplicate entries are summed together:

```
>>> row = np.array([0, 1, 2, 0])
>>> col = np.array([0, 1, 1, 0])
>>> data = np.array([1, 2, 4, 8])
>>> csr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[9, 0, 0],
       [0, 2, 0],
       [0, 4, 0]])
```

As an example of how to construct a CSR matrix incrementally, the following snippet builds a term-document matrix from texts:

```
>>> docs = [["hello", "world", "hello"], ["goodbye", "cruel", "world"]]
>>> indptr = [0]
>>> indices = []
>>> data = []
>>> vocabulary = {}
>>> for d in docs:
...     for term in d:
...         index = vocabulary.setdefault(term, len(vocabulary))
...         indices.append(index)
...         data.append(1)
...     indptr.append(len(indices))
...
>>> csr_matrix((data, indices, indptr), dtype=int).toarray()
array([[2, 1, 0, 0],
       [0, 1, 1, 1]])
```

Attributes

dtype [dtype] Data type of the matrix
shape [2-tuple] Get shape of a matrix.
ndim [int] Number of dimensions (this is always 2)
nnz Number of stored values, including explicit zeros.
data CSR format data array of the matrix
indices CSR format index array of the matrix
indptr CSR format index pointer array of the matrix
has_sorted_indices
Determine whether the matrix has sorted indices

Methods

__len__()	
__mul__(other)	interpret other and call one of the following
arcsin()	Element-wise arcsin.
arcsinh()	Element-wise arcsinh.
arctan()	Element-wise arctan.
arctanh()	Element-wise arctanh.
argmax([axis, out])	Return indices of maximum elements along an axis.
argmin([axis, out])	Return indices of minimum elements along an axis.
asformat(format[, copy])	Return this matrix in the passed format.
asfptype()	Upcast matrix to a floating point format (if necessary)
astype(dtype[, casting, copy])	Cast the matrix elements to a specified type.
ceil()	Element-wise ceil.
check_format([full_check])	check whether the matrix format is valid
conj([copy])	Element-wise complex conjugation.
conjugate([copy])	Element-wise complex conjugation.
copy()	Returns a copy of this matrix.
count_nonzero()	Number of non-zero entries, equivalent to
deg2rad()	Element-wise deg2rad.
diagonal([k])	Returns the kth diagonal of the matrix.
dot(other)	Ordinary dot product
eliminate_zeros()	Remove zero entries from the matrix
expm1()	Element-wise expm1.
floor()	Element-wise floor.
getH()	Return the Hermitian transpose of this matrix.
get_shape()	Get shape of a matrix.
getcol(i)	Returns a copy of column i of the matrix, as a (m x 1) CSR matrix (column vector).
getformat()	Format of a matrix representation as a string.
getmaxprint()	Maximum number of elements to display when printed.
getnnz([axis])	Number of stored values, including explicit zeros.
getrow(i)	Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
log1p()	Element-wise log1p.
max([axis, out])	Return the maximum of the matrix or maximum along an axis.

continues on next page

Table 178 – continued from previous page

maximum(other)	Element-wise maximum between this and another matrix.
mean([axis, dtype, out])	Compute the arithmetic mean along the specified axis.
min([axis, out])	Return the minimum of the matrix or maximum along an axis.
minimum(other)	Element-wise minimum between this and another matrix.
multiply(other)	Point-wise multiplication by another matrix, vector, or scalar.
nonzero()	nonzero indices
power(n[, dtype])	This function performs element-wise power.
prune()	Remove empty space after all non-zero elements.
rad2deg()	Element-wise rad2deg.
reshape(self, shape[, order, copy])	Gives a new shape to a sparse matrix without changing its data.
resize(*shape)	Resize the matrix in-place to dimensions given by `shape`
rint()	Element-wise rint.
set_shape(shape)	See *reshape*.
setdiag(values[, k])	Set diagonal or off-diagonal elements of the array.
sign()	Element-wise sign.
sin()	Element-wise sin.
sinh()	Element-wise sinh.
sort_indices()	Sort the indices of this matrix *in place*
sorted_indices()	Return a copy of this matrix with sorted indices
sqrt()	Element-wise sqrt.
sum([axis, dtype, out])	Sum the matrix elements over a given axis.
sum_duplicates()	Eliminate duplicate matrix entries by adding them together
tan()	Element-wise tan.
tanh()	Element-wise tanh.
toarray([order, out])	Return a dense ndarray representation of this matrix.
tobsr([blocksize, copy])	Convert this matrix to Block Sparse Row format.
tocoo([copy])	Convert this matrix to COOrdinate format.
tocsc([copy])	Convert this matrix to Compressed Sparse Column format.
tocsr([copy])	Convert this matrix to Compressed Sparse Row format.
todense([order, out])	Return a dense matrix representation of this matrix.
todia([copy])	Convert this matrix to sparse DIAgonal format.
todok([copy])	Convert this matrix to Dictionary Of Keys format.
tolil([copy])	Convert this matrix to List of Lists format.
transpose([axes, copy])	Reverses the dimensions of the sparse matrix.
trunc()	Element-wise trunc.

scipy.sparse.csr_matrix.__len__

csr_matrix.**__len__**()

scipy.sparse.csr_matrix.__mul__

csr_matrix.**__mul__**(*other*)
interpret other and call one of the following

self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

scipy.sparse.csr_matrix.arcsin

csr_matrix.**arcsin**()
Element-wise arcsin.

See numpy.arcsin for more information.

scipy.sparse.csr_matrix.arcsinh

csr_matrix.**arcsinh**()
Element-wise arcsinh.

See numpy.arcsinh for more information.

scipy.sparse.csr_matrix.arctan

csr_matrix.**arctan**()
Element-wise arctan.

See numpy.arctan for more information.

scipy.sparse.csr_matrix.arctanh

csr_matrix.**arctanh**()
Element-wise arctanh.

See numpy.arctanh for more information.

scipy.sparse.csr_matrix.argmax

csr_matrix.**argmax**(*axis=None*, *out=None*)
Return indices of maximum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

Parameters

axis [{-2, -1, 0, 1, None}, optional] Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

ind [numpy.matrix or int] Indices of maximum elements. If matrix, its size along *axis* is 1.

scipy.sparse.csr_matrix.argmin

csr_matrix.**argmin**(*axis=None*, *out=None*)

Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

Parameters

axis [{-2, -1, 0, 1, None}, optional] Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

ind [numpy.matrix or int] Indices of minimum elements. If matrix, its size along *axis* is 1.

scipy.sparse.csr_matrix.asformat

csr_matrix.**asformat**(*format*, *copy=False*)

Return this matrix in the passed format.

Parameters

format [{str, None}] The desired matrix format ("csr", "csc", "lil", "dok", "array", …) or None for no conversion.

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [This matrix in the passed format.]

scipy.sparse.csr_matrix.asfptype

csr_matrix.**asfptype**()

Upcast matrix to a floating point format (if necessary)

scipy.sparse.csr_matrix.astype

csr_matrix.**astype**(*dtype*, *casting='unsafe'*, *copy=True*)

Cast the matrix elements to a specified type.

Parameters

dtype [string or numpy dtype] Typecode or data-type to which to cast the data.

casting [{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.

copy [bool, optional] If *copy* is *False*, the result might share some memory with this matrix. If *copy* is *True*, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.csr_matrix.ceil

csr_matrix.**ceil**()

Element-wise ceil.

See numpy.ceil for more information.

scipy.sparse.csr_matrix.check_format

csr_matrix.**check_format**(*full_check=True*)

check whether the matrix format is valid

Parameters

full_check [bool, optional] If *True*, rigorous check, O(N) operations. Otherwise basic check, O(1) operations (default True).

scipy.sparse.csr_matrix.conj

csr_matrix.**conj**(*copy=True*)

Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.csr_matrix.conjugate

csr_matrix.**conjugate**(*copy=True*)

Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.csr_matrix.copy

csr_matrix.**copy**()

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

scipy.sparse.csr_matrix.count_nonzero

csr_matrix.**count_nonzero**()

Number of non-zero entries, equivalent to

np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.csr_matrix.deg2rad

csr_matrix.**deg2rad**()

Element-wise deg2rad.

See numpy.deg2rad for more information.

scipy.sparse.csr_matrix.diagonal

csr_matrix.**diagonal**(*k=0*)

Returns the kth diagonal of the matrix.

Parameters

k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
New in version 1.0.

See also:

numpy.diagonal

Equivalent numpy function.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.csr_matrix.dot

csr_matrix.**dot**(*other*)
Ordinary dot product

Examples

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.csr_matrix.eliminate_zeros

csr_matrix.**eliminate_zeros**()
Remove zero entries from the matrix

This is an *in place* operation.

scipy.sparse.csr_matrix.expm1

csr_matrix.**expm1**()
Element-wise expm1.

See numpy.expm1 for more information.

scipy.sparse.csr_matrix.floor

csr_matrix.**floor**()
Element-wise floor.

See numpy.floor for more information.

scipy.sparse.csr_matrix.getH

csr_matrix.**getH**()
Return the Hermitian transpose of this matrix.

See also:

numpy.matrix.getH

NumPy's implementation of *getH* for matrices

scipy.sparse.csr_matrix.get_shape

csr_matrix.**get_shape**()
Get shape of a matrix.

scipy.sparse.csr_matrix.getcol

csr_matrix.**getcol**(*i*)
Returns a copy of column i of the matrix, as a (m x 1) CSR matrix (column vector).

scipy.sparse.csr_matrix.getformat

csr_matrix.**getformat**()
Format of a matrix representation as a string.

scipy.sparse.csr_matrix.getmaxprint

csr_matrix.**getmaxprint**()
Maximum number of elements to display when printed.

scipy.sparse.csr_matrix.getnnz

csr_matrix.**getnnz**(*axis=None*)
Number of stored values, including explicit zeros.

Parameters

axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:

count_nonzero

Number of non-zero entries

scipy.sparse.csr_matrix.getrow

csr_matrix.**getrow**(*i*)
Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).

scipy.sparse.csr_matrix.log1p

csr_matrix.**log1p**()
Element-wise log1p.

See numpy.log1p for more information.

scipy.sparse.csr_matrix.max

csr_matrix.**max**(*axis=None*, *out=None*)
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e., *axis* = *None*).

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amax [coo_matrix or scalar] Maximum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

min

The minimum value of a sparse matrix along a given axis.

numpy.matrix.max

NumPy's implementation of 'max' for matrices

scipy.sparse.csr_matrix.maximum

csr_matrix.**maximum**(*other*)
Element-wise maximum between this and another matrix.

scipy.sparse.csr_matrix.mean

csr_matrix.**mean**(*axis=None*, *dtype=None*, *out=None*)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., *axis* = *None*).

dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

m [np.matrix]

See also:

numpy.matrix.mean

NumPy's implementation of 'mean' for matrices

scipy.sparse.csr_matrix.min

csr_matrix.**min**(*axis=None*, *out=None*)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e., *axis* = *None*).

out [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amin [coo_matrix or scalar] Minimum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a sparse.coo_matrix of dimension `a.ndim - 1`.

See also:

max

The maximum value of a sparse matrix along a given axis.

numpy.matrix.min

NumPy's implementation of 'min' for matrices

scipy.sparse.csr_matrix.minimum

csr_matrix.**minimum**(*other*)
Element-wise minimum between this and another matrix.

scipy.sparse.csr_matrix.multiply

csr_matrix.**multiply**(*other*)
Point-wise multiplication by another matrix, vector, or scalar.

scipy.sparse.csr_matrix.nonzero

csr_matrix.**nonzero**()
nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.csr_matrix.power

csr_matrix.**power**(*n*, *dtype=None*)
This function performs element-wise power.

Parameters

n	[n is a scalar]
dtype	[If dtype is not specified, the current dtype will be preserved.]

scipy.sparse.csr_matrix.prune

csr_matrix.**prune**()
Remove empty space after all non-zero elements.

scipy.sparse.csr_matrix.rad2deg

csr_matrix.**rad2deg**()
Element-wise rad2deg.

See numpy.rad2deg for more information.

scipy.sparse.csr_matrix.reshape

csr_matrix.**reshape**(*self*, *shape*, *order='C'*, *copy=False*)

Gives a new shape to a sparse matrix without changing its data.

Parameters

shape [length-2 tuple of ints] The new shape should be compatible with the original shape.

order [{'C', 'F'}, optional] Read the elements using this index order. 'C' means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. 'F' means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.

copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

reshaped_matrix

[sparse matrix] A sparse matrix with the given `shape`, not necessarily of the same format as the current object.

See also:

numpy.matrix.reshape

NumPy's implementation of 'reshape' for matrices

scipy.sparse.csr_matrix.resize

csr_matrix.**resize**(**shape*)

Resize the matrix in-place to dimensions given by `shape`

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

shape [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

scipy.sparse.csr_matrix.rint

csr_matrix.**rint**()
Element-wise rint.

See numpy.rint for more information.

scipy.sparse.csr_matrix.set_shape

csr_matrix.**set_shape**(*shape*)
See *reshape*.

scipy.sparse.csr_matrix.setdiag

csr_matrix.**setdiag**(*values*, *k=0*)
Set diagonal or off-diagonal elements of the array.

Parameters

values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

scipy.sparse.csr_matrix.sign

csr_matrix.**sign**()
Element-wise sign.

See numpy.sign for more information.

scipy.sparse.csr_matrix.sin

csr_matrix.**sin**()
Element-wise sin.

See numpy.sin for more information.

scipy.sparse.csr_matrix.sinh

csr_matrix.**sinh**()
Element-wise sinh.

See numpy.sinh for more information.

scipy.sparse.csr_matrix.sort_indices

csr_matrix.**sort_indices**()
Sort the indices of this matrix *in place*

scipy.sparse.csr_matrix.sorted_indices

csr_matrix.**sorted_indices**()
Return a copy of this matrix with sorted indices

scipy.sparse.csr_matrix.sqrt

csr_matrix.**sqrt**()
Element-wise sqrt.

See numpy.sqrt for more information.

scipy.sparse.csr_matrix.sum

csr_matrix.**sum**(*axis=None*, *dtype=None*, *out=None*)
Sum the matrix elements over a given axis.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., *axis* = *None*).

dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

sum_along_axis
[np.matrix] A matrix with the same shape as *self*, with the specified axis removed.

See also:

numpy.matrix.sum

NumPy's implementation of 'sum' for matrices

scipy.sparse.csr_matrix.sum_duplicates

csr_matrix.**sum_duplicates**()
Eliminate duplicate matrix entries by adding them together

This is an *in place* operation.

scipy.sparse.csr_matrix.tan

csr_matrix.**tan**()
Element-wise tan.

See numpy.tan for more information.

scipy.sparse.csr_matrix.tanh

csr_matrix.**tanh**()
Element-wise tanh.

See numpy.tanh for more information.

scipy.sparse.csr_matrix.toarray

csr_matrix.**toarray**(*order=None*, *out=None*)
Return a dense ndarray representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

Returns

arr [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.csr_matrix.tobsr

csr_matrix.**tobsr**(*blocksize=None*, *copy=True*)
Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

scipy.sparse.csr_matrix.tocoo

csr_matrix.**tocoo**(*copy=True*)
Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.csr_matrix.tocsc

csr_matrix.**tocsc**(*copy=False*)
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.csr_matrix.tocsr

csr_matrix.**tocsr**(*copy=False*)
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.csr_matrix.todense

csr_matrix.**todense**(*order=None*, *out=None*)
Return a dense matrix representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out [ndarray, 2-D, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

scipy.sparse.csr_matrix.todia

csr_matrix.**todia**(*copy=False*)
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.csr_matrix.todok

csr_matrix.**todok**(*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.csr_matrix.tolil

csr_matrix.**tolil**(*copy=False*)

Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.csr_matrix.transpose

csr_matrix.**transpose**(*axes=None*, *copy=False*)

Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

copy [bool, optional] Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [*self* with the dimensions reversed.]

See also:

numpy.matrix.transpose

NumPy's implementation of 'transpose' for matrices

scipy.sparse.csr_matrix.trunc

csr_matrix.**trunc**()

Element-wise trunc.

See numpy.trunc for more information.

__getitem__	

scipy.sparse.dia_matrix

class scipy.sparse.**dia_matrix**(*arg1*, *shape=None*, *dtype=None*, *copy=False*)

Sparse matrix with DIAgonal storage

This can be instantiated in several ways:

dia_matrix(D)

with a dense matrix

dia_matrix(S)

with another sparse matrix S (equivalent to S.todia())

dia_matrix((M, N), [dtype])

to construct an empty matrix with shape (M, N), dtype is optional, defaulting to dtype='d'.

dia_matrix((data, offsets), shape=(M, N))

where the `data[k,:]` stores the diagonal entries for diagonal `offsets[k]` (See example below)

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Examples

```
>>> import numpy as np
>>> from scipy.sparse import dia_matrix
>>> dia_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```
>>> data = np.array([[1, 2, 3, 4]]).repeat(3, axis=0)
>>> offsets = np.array([0, -1, 2])
>>> dia_matrix((data, offsets), shape=(4, 4)).toarray()
array([[1, 0, 3, 0],
       [1, 2, 0, 4],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```

```
>>> from scipy.sparse import dia_matrix
>>> n = 10
>>> ex = np.ones(n)
>>> data = np.array([ex, 2 * ex, ex])
>>> offsets = np.array([-1, 0, 1])
>>> dia_matrix((data, offsets), shape=(n, n)).toarray()
array([[2., 1., 0., ..., 0., 0., 0.],
       [1., 2., 1., ..., 0., 0., 0.],
```

(continues on next page)

(continued from previous page)

```
       [0., 1., 2., ..., 0., 0., 0.],
       ...,
       [0., 0., 0., ..., 2., 1., 0.],
       [0., 0., 0., ..., 1., 2., 1.],
       [0., 0., 0., ..., 0., 1., 2.]])
```

Attributes

dtype	[dtype] Data type of the matrix
shape	[2-tuple] Get shape of a matrix.
ndim	[int] Number of dimensions (this is always 2)
nnz	Number of stored values, including explicit zeros.
data	DIA format data array of the matrix
offsets	DIA format offset array of the matrix

Methods

__len__()	
__mul__(other)	interpret other and call one of the following
arcsin()	Element-wise arcsin.
arcsinh()	Element-wise arcsinh.
arctan()	Element-wise arctan.
arctanh()	Element-wise arctanh.
asformat(format[, copy])	Return this matrix in the passed format.
asfptype()	Upcast matrix to a floating point format (if necessary)
astype(dtype[, casting, copy])	Cast the matrix elements to a specified type.
ceil()	Element-wise ceil.
conj([copy])	Element-wise complex conjugation.
conjugate([copy])	Element-wise complex conjugation.
copy()	Returns a copy of this matrix.
count_nonzero()	Number of non-zero entries, equivalent to
deg2rad()	Element-wise deg2rad.
diagonal([k])	Returns the kth diagonal of the matrix.
dot(other)	Ordinary dot product
expm1()	Element-wise expm1.
floor()	Element-wise floor.
getH()	Return the Hermitian transpose of this matrix.
get_shape()	Get shape of a matrix.
getcol(j)	Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
getformat()	Format of a matrix representation as a string.
getmaxprint()	Maximum number of elements to display when printed.
getnnz([axis])	Number of stored values, including explicit zeros.
getrow(i)	Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
log1p()	Element-wise log1p.

continues on next page

Table 179 – continued from previous page

maximum(other)	Element-wise maximum between this and another matrix.
mean([axis, dtype, out])	Compute the arithmetic mean along the specified axis.
minimum(other)	Element-wise minimum between this and another matrix.
multiply(other)	Point-wise multiplication by another matrix
nonzero()	nonzero indices
power(n[, dtype])	This function performs element-wise power.
rad2deg()	Element-wise rad2deg.
reshape(self, shape[, order, copy])	Gives a new shape to a sparse matrix without changing its data.
resize(*shape)	Resize the matrix in-place to dimensions given by `shape`
rint()	Element-wise rint.
set_shape(shape)	See *reshape*.
setdiag(values[, k])	Set diagonal or off-diagonal elements of the array.
sign()	Element-wise sign.
sin()	Element-wise sin.
sinh()	Element-wise sinh.
sqrt()	Element-wise sqrt.
sum([axis, dtype, out])	Sum the matrix elements over a given axis.
tan()	Element-wise tan.
tanh()	Element-wise tanh.
toarray([order, out])	Return a dense ndarray representation of this matrix.
tobsr([blocksize, copy])	Convert this matrix to Block Sparse Row format.
tocoo([copy])	Convert this matrix to COOrdinate format.
tocsc([copy])	Convert this matrix to Compressed Sparse Column format.
tocsr([copy])	Convert this matrix to Compressed Sparse Row format.
todense([order, out])	Return a dense matrix representation of this matrix.
todia([copy])	Convert this matrix to sparse DIAgonal format.
todok([copy])	Convert this matrix to Dictionary Of Keys format.
tolil([copy])	Convert this matrix to List of Lists format.
transpose([axes, copy])	Reverses the dimensions of the sparse matrix.
trunc()	Element-wise trunc.

scipy.sparse.dia_matrix.__len__

dia_matrix.**__len__**()

scipy.sparse.dia_matrix.__mul__

dia_matrix.**__mul__**(*other*)
interpret other and call one of the following

self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

scipy.sparse.dia_matrix.arcsin

dia_matrix.**arcsin**()
Element-wise arcsin.

See numpy.arcsin for more information.

scipy.sparse.dia_matrix.arcsinh

dia_matrix.**arcsinh**()
Element-wise arcsinh.

See numpy.arcsinh for more information.

scipy.sparse.dia_matrix.arctan

dia_matrix.**arctan**()
Element-wise arctan.

See numpy.arctan for more information.

scipy.sparse.dia_matrix.arctanh

dia_matrix.**arctanh**()
Element-wise arctanh.

See numpy.arctanh for more information.

scipy.sparse.dia_matrix.asformat

dia_matrix.**asformat**(*format*, *copy=False*)
Return this matrix in the passed format.

Parameters

format [{str, None}] The desired matrix format ("csr", "csc", "lil", "dok", "array", …) or None for no conversion.

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [This matrix in the passed format.]

scipy.sparse.dia_matrix.asfptype

dia_matrix.**asfptype**()
Upcast matrix to a floating point format (if necessary)

scipy.sparse.dia_matrix.astype

dia_matrix.**astype**(*dtype*, *casting='unsafe'*, *copy=True*)
Cast the matrix elements to a specified type.

Parameters

dtype [string or numpy dtype] Typecode or data-type to which to cast the data.
casting [{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.
copy [bool, optional] If *copy* is *False*, the result might share some memory with this matrix. If *copy* is *True*, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.dia_matrix.ceil

dia_matrix.**ceil**()
Element-wise ceil.

See numpy.ceil for more information.

scipy.sparse.dia_matrix.conj

dia_matrix.**conj**(*copy=True*)
Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.dia_matrix.conjugate

dia_matrix.**conjugate**(*copy=True*)

Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.dia_matrix.copy

dia_matrix.**copy**()

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

scipy.sparse.dia_matrix.count_nonzero

dia_matrix.**count_nonzero**()

Number of non-zero entries, equivalent to

np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.dia_matrix.deg2rad

dia_matrix.**deg2rad**()

Element-wise deg2rad.

See numpy.deg2rad for more information.

scipy.sparse.dia_matrix.diagonal

dia_matrix.**diagonal**(*k=0*)

Returns the kth diagonal of the matrix.

Parameters

k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
New in version 1.0.

See also:

numpy.diagonal

Equivalent numpy function.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.dia_matrix.dot

dia_matrix.**dot**(*other*)
Ordinary dot product

Examples

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.dia_matrix.expm1

dia_matrix.**expm1**()
Element-wise expm1.

See numpy.expm1 for more information.

scipy.sparse.dia_matrix.floor

dia_matrix.**floor**()
Element-wise floor.

See numpy.floor for more information.

scipy.sparse.dia_matrix.getH

dia_matrix.**getH**()
Return the Hermitian transpose of this matrix.

See also:

numpy.matrix.getH

NumPy's implementation of *getH* for matrices

scipy.sparse.dia_matrix.get_shape

dia_matrix.**get_shape**()
Get shape of a matrix.

scipy.sparse.dia_matrix.getcol

dia_matrix.**getcol**(*j*)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.dia_matrix.getformat

dia_matrix.**getformat**()
Format of a matrix representation as a string.

scipy.sparse.dia_matrix.getmaxprint

dia_matrix.**getmaxprint**()
Maximum number of elements to display when printed.

scipy.sparse.dia_matrix.getnnz

dia_matrix.**getnnz**(*axis=None*)
Number of stored values, including explicit zeros.

Parameters

axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:

count_nonzero

Number of non-zero entries

scipy.sparse.dia_matrix.getrow

dia_matrix.**getrow**(*i*)
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.dia_matrix.log1p

dia_matrix.**log1p**()
Element-wise log1p.

See numpy.log1p for more information.

scipy.sparse.dia_matrix.maximum

dia_matrix.**maximum**(*other*)
Element-wise maximum between this and another matrix.

scipy.sparse.dia_matrix.mean

dia_matrix.**mean**(*axis=None*, *dtype=None*, *out=None*)
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., *axis* = *None*).

dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

m [np.matrix]

See also:

numpy.matrix.mean

NumPy's implementation of 'mean' for matrices

scipy.sparse.dia_matrix.minimum

dia_matrix.**minimum**(*other*)
Element-wise minimum between this and another matrix.

scipy.sparse.dia_matrix.multiply

dia_matrix.**multiply**(*other*)
Point-wise multiplication by another matrix

scipy.sparse.dia_matrix.nonzero

dia_matrix.**nonzero**()
nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.dia_matrix.power

dia_matrix.**power**(*n*, *dtype=None*)
This function performs element-wise power.

Parameters

n	[n is a scalar]
dtype	[If dtype is not specified, the current dtype will be preserved.]

scipy.sparse.dia_matrix.rad2deg

dia_matrix.**rad2deg**()
Element-wise rad2deg.

See numpy.rad2deg for more information.

scipy.sparse.dia_matrix.reshape

dia_matrix.**reshape**(*self*, *shape*, *order='C'*, *copy=False*)
Gives a new shape to a sparse matrix without changing its data.

Parameters

shape	[length-2 tuple of ints] The new shape should be compatible with the original shape.
order	[{'C', 'F'}, optional] Read the elements using this index order. 'C' means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. 'F' means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
copy	[bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

reshaped_matrix
[sparse matrix] A sparse matrix with the given `shape`, not necessarily of the same format as the current object.

See also:

numpy.matrix.reshape

NumPy's implementation of 'reshape' for matrices

scipy.sparse.dia_matrix.resize

`dia_matrix.`**`resize`**`(*shape)`
Resize the matrix in-place to dimensions given by `shape`

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

shape [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

scipy.sparse.dia_matrix.rint

`dia_matrix.`**`rint`**`()`
Element-wise rint.

See `numpy.rint` for more information.

scipy.sparse.dia_matrix.set_shape

`dia_matrix.`**`set_shape`**`(shape)`
See *reshape*.

scipy.sparse.dia_matrix.setdiag

dia_matrix.**setdiag**(*values*, *k=0*)

Set diagonal or off-diagonal elements of the array.

Parameters

values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

scipy.sparse.dia_matrix.sign

dia_matrix.**sign**()

Element-wise sign.

See numpy.sign for more information.

scipy.sparse.dia_matrix.sin

dia_matrix.**sin**()

Element-wise sin.

See numpy.sin for more information.

scipy.sparse.dia_matrix.sinh

dia_matrix.**sinh**()

Element-wise sinh.

See numpy.sinh for more information.

scipy.sparse.dia_matrix.sqrt

dia_matrix.**sqrt**()

Element-wise sqrt.

See numpy.sqrt for more information.

scipy.sparse.dia_matrix.sum

dia_matrix.**sum**(*axis=None*, *dtype=None*, *out=None*)

Sum the matrix elements over a given axis.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., *axis* = *None*).

dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

sum_along_axis
[np.matrix] A matrix with the same shape as *self*, with the specified axis removed.

See also:

numpy.matrix.sum

NumPy's implementation of 'sum' for matrices

scipy.sparse.dia_matrix.tan

dia_matrix.**tan**()

Element-wise tan.

See numpy.tan for more information.

scipy.sparse.dia_matrix.tanh

dia_matrix.**tanh**()

Element-wise tanh.

See numpy.tanh for more information.

scipy.sparse.dia_matrix.toarray

dia_matrix.**toarray**(*order=None*, *out=None*)

Return a dense ndarray representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

Returns

arr [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.dia_matrix.tobsr

dia_matrix.**tobsr**(*blocksize=None*, *copy=False*)

Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

scipy.sparse.dia_matrix.tocoo

dia_matrix.**tocoo**(*copy=False*)

Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.dia_matrix.tocsc

dia_matrix.**tocsc**(*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.dia_matrix.tocsr

dia_matrix.**tocsr**(*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.dia_matrix.todense

dia_matrix.**todense**(*order=None*, *out=None*)

Return a dense matrix representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out [ndarray, 2-D, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

scipy.sparse.dia_matrix.todia

dia_matrix.**todia**(*copy=False*)

Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.dia_matrix.todok

dia_matrix.**todok**(*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.dia_matrix.tolil

dia_matrix.**tolil**(*copy=False*)

Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.dia_matrix.transpose

dia_matrix.**transpose**(*axes=None*, *copy=False*)

Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

copy [bool, optional] Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [*self* with the dimensions reversed.]

See also:

numpy.matrix.transpose

NumPy's implementation of 'transpose' for matrices

scipy.sparse.dia_matrix.trunc

dia_matrix.**trunc**()

Element-wise trunc.

See numpy.trunc for more information.

scipy.sparse.dok_matrix

class scipy.sparse.**dok_matrix**(*arg1*, *shape=None*, *dtype=None*, *copy=False*)

Dictionary Of Keys based sparse matrix.

This is an efficient structure for constructing sparse matrices incrementally.

This can be instantiated in several ways:

dok_matrix(D)

with a dense matrix, D

dok_matrix(S)

with a sparse matrix, S

dok_matrix((M,N), [dtype])

create the matrix with initial shape (M,N) dtype is optional, defaulting to dtype='d'

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Allows for efficient O(1) access of individual elements. Duplicates are not allowed. Can be efficiently converted to a coo_matrix once constructed.

Examples

```
>>> import numpy as np
>>> from scipy.sparse import dok_matrix
>>> S = dok_matrix((5, 5), dtype=np.float32)
>>> for i in range(5):
...     for j in range(5):
...         S[i, j] = i + j     # Update element
```

Attributes

dtype	[dtype] Data type of the matrix
shape	[2-tuple] Get shape of a matrix.
ndim	[int] Number of dimensions (this is always 2)
nnz	Number of stored values, including explicit zeros.

Methods

__len__()	Return len(self).
__mul__(other)	interpret other and call one of the following
asformat(format[, copy])	Return this matrix in the passed format.
asfptype()	Upcast matrix to a floating point format (if necessary)
astype(dtype[, casting, copy])	Cast the matrix elements to a specified type.
clear()	
conj([copy])	Element-wise complex conjugation.
conjtransp()	Return the conjugate transpose.
conjugate([copy])	Element-wise complex conjugation.
copy()	Returns a copy of this matrix.
count_nonzero()	Number of non-zero entries, equivalent to
diagonal([k])	Returns the kth diagonal of the matrix.
dot(other)	Ordinary dot product
fromkeys(iterable[, value])	Create a new dictionary with keys from iterable and values set to value.
get(key[, default])	This overrides the dict.get method, providing type checking but otherwise equivalent functionality.
getH()	Return the Hermitian transpose of this matrix.
get_shape()	Get shape of a matrix.
getcol(j)	Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
getformat()	Format of a matrix representation as a string.

continues on next page

Table 180 – continued from previous page

getmaxprint()	Maximum number of elements to display when printed.
getnnz([axis])	Number of stored values, including explicit zeros.
getrow(i)	Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
items()	
keys()	
maximum(other)	Element-wise maximum between this and another matrix.
mean([axis, dtype, out])	Compute the arithmetic mean along the specified axis.
minimum(other)	Element-wise minimum between this and another matrix.
multiply(other)	Point-wise multiplication by another matrix
nonzero()	nonzero indices
pop(k[,d])	If key is not found, d is returned if given, otherwise KeyError is raised
popitem(/)	Remove and return a (key, value) pair as a 2-tuple.
power(n[, dtype])	Element-wise power.
reshape(self, shape[, order, copy])	Gives a new shape to a sparse matrix without changing its data.
resize(*shape)	Resize the matrix in-place to dimensions given by `shape`
set_shape(shape)	See reshape.
setdefault(key[, default])	Insert key with a value of default if key is not in the dictionary.
setdiag(values[, k])	Set diagonal or off-diagonal elements of the array.
sum([axis, dtype, out])	Sum the matrix elements over a given axis.
toarray([order, out])	Return a dense ndarray representation of this matrix.
tobsr([blocksize, copy])	Convert this matrix to Block Sparse Row format.
tocoo([copy])	Convert this matrix to COOrdinate format.
tocsc([copy])	Convert this matrix to Compressed Sparse Column format.
tocsr([copy])	Convert this matrix to Compressed Sparse Row format.
todense([order, out])	Return a dense matrix representation of this matrix.
todia([copy])	Convert this matrix to sparse DIAgonal format.
todok([copy])	Convert this matrix to Dictionary Of Keys format.
tolil([copy])	Convert this matrix to List of Lists format.
transpose([axes, copy])	Reverses the dimensions of the sparse matrix.
update([E,]**F)	If E is present and has a .keys() method, then does: for k in E: D[k] = E[k] If E is present and lacks a .keys() method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]
values()	

scipy.sparse.dok_matrix.__len__

dok_matrix.**__len__**()
Return len(self).

scipy.sparse.dok_matrix.__mul__

dok_matrix.**__mul__**(*other*)
interpret other and call one of the following

self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

scipy.sparse.dok_matrix.asformat

dok_matrix.**asformat**(*format*, *copy=False*)
Return this matrix in the passed format.

Parameters

format [{str, None}] The desired matrix format ("csr", "csc", "lil", "dok", "array", …) or None for no conversion.
copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [This matrix in the passed format.]

scipy.sparse.dok_matrix.asfptype

dok_matrix.**asfptype**()
Upcast matrix to a floating point format (if necessary)

scipy.sparse.dok_matrix.astype

dok_matrix.**astype**(*dtype*, *casting='unsafe'*, *copy=True*)
Cast the matrix elements to a specified type.

Parameters

dtype [string or numpy dtype] Typecode or data-type to which to cast the data.
casting [{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.
copy [bool, optional] If `copy` is *False*, the result might share some memory with this matrix. If `copy` is *True*, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.dok_matrix.clear

dok_matrix.**clear**() → None. Remove all items from D.

scipy.sparse.dok_matrix.conj

dok_matrix.**conj**(*copy=True*)

Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.dok_matrix.conjtransp

dok_matrix.**conjtransp**()

Return the conjugate transpose.

scipy.sparse.dok_matrix.conjugate

dok_matrix.**conjugate**(*copy=True*)

Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.dok_matrix.copy

dok_matrix.**copy**()

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

scipy.sparse.dok_matrix.count_nonzero

dok_matrix.**count_nonzero**()
Number of non-zero entries, equivalent to

np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.dok_matrix.diagonal

dok_matrix.**diagonal**(*k=0*)
Returns the kth diagonal of the matrix.

Parameters

k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
New in version 1.0.

See also:

numpy.diagonal

Equivalent numpy function.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.dok_matrix.dot

dok_matrix.**dot**(*other*)
Ordinary dot product

Examples

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.dok_matrix.fromkeys

dok_matrix.**fromkeys**(*iterable*, *value=None*, */*)
Create a new dictionary with keys from iterable and values set to value.

scipy.sparse.dok_matrix.get

dok_matrix.**get**(*key*, *default=0.0*)
This overrides the dict.get method, providing type checking but otherwise equivalent functionality.

scipy.sparse.dok_matrix.getH

dok_matrix.**getH**()
Return the Hermitian transpose of this matrix.

See also:

numpy.matrix.getH

NumPy's implementation of *getH* for matrices

scipy.sparse.dok_matrix.get_shape

dok_matrix.**get_shape**()
Get shape of a matrix.

scipy.sparse.dok_matrix.getcol

dok_matrix.**getcol**(*j*)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.dok_matrix.getformat

dok_matrix.**getformat**()
Format of a matrix representation as a string.

scipy.sparse.dok_matrix.getmaxprint

dok_matrix.**getmaxprint**()
Maximum number of elements to display when printed.

scipy.sparse.dok_matrix.getnnz

dok_matrix.**getnnz**(*axis=None*)
Number of stored values, including explicit zeros.

Parameters

axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:

count_nonzero

Number of non-zero entries

scipy.sparse.dok_matrix.getrow

dok_matrix.**getrow**(*i*)
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.dok_matrix.items

dok_matrix.**items**() → a set-like object providing a view on D's items

scipy.sparse.dok_matrix.keys

dok_matrix.**keys**() → a set-like object providing a view on D's keys

scipy.sparse.dok_matrix.maximum

dok_matrix.**maximum**(*other*)
Element-wise maximum between this and another matrix.

scipy.sparse.dok_matrix.mean

dok_matrix.**mean**(*axis=None*, *dtype=None*, *out=None*)
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., *axis* = *None*).

dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

m [np.matrix]

See also:

numpy.matrix.mean

NumPy's implementation of 'mean' for matrices

scipy.sparse.dok_matrix.minimum

dok_matrix.**minimum**(*other*)
Element-wise minimum between this and another matrix.

scipy.sparse.dok_matrix.multiply

dok_matrix.**multiply**(*other*)
Point-wise multiplication by another matrix

scipy.sparse.dok_matrix.nonzero

dok_matrix.**nonzero**()
nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.dok_matrix.pop

dok_matrix.**pop**($k[, d]$) $\rightarrow$ v, remove specified key and return the corresponding value.
If key is not found, d is returned if given, otherwise KeyError is raised

scipy.sparse.dok_matrix.popitem

dok_matrix.**popitem**(/)
Remove and return a (key, value) pair as a 2-tuple.

Pairs are returned in LIFO (last-in, first-out) order. Raises KeyError if the dict is empty.

scipy.sparse.dok_matrix.power

dok_matrix.**power**(*n*, *dtype=None*)
Element-wise power.

scipy.sparse.dok_matrix.reshape

dok_matrix.**reshape**(*self*, *shape*, *order='C'*, *copy=False*)
Gives a new shape to a sparse matrix without changing its data.

Parameters

shape [length-2 tuple of ints] The new shape should be compatible with the original shape.
order [{'C', 'F'}, optional] Read the elements using this index order. 'C' means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. 'F' means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

reshaped_matrix
[sparse matrix] A sparse matrix with the given `shape`, not necessarily of the same format as the current object.

See also:

numpy.matrix.reshape

NumPy's implementation of 'reshape' for matrices

scipy.sparse.dok_matrix.resize

dok_matrix.**resize**(**shape*)
Resize the matrix in-place to dimensions given by `shape`

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

shape [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

scipy.sparse.dok_matrix.set_shape

dok_matrix.**set_shape**(*shape*)
See *reshape*.

scipy.sparse.dok_matrix.setdefault

dok_matrix.**setdefault**(*key*, *default=None*, */*)
Insert key with a value of default if key is not in the dictionary.

Return the value for key if key is in the dictionary, else default.

scipy.sparse.dok_matrix.setdiag

dok_matrix.**setdiag**(*values*, *k=0*)
Set diagonal or off-diagonal elements of the array.

Parameters

values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

scipy.sparse.dok_matrix.sum

dok_matrix.**sum**(*axis=None*, *dtype=None*, *out=None*)
Sum the matrix elements over a given axis.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., *axis* = *None*).

dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

sum_along_axis
[np.matrix] A matrix with the same shape as *self*, with the specified axis removed.

See also:

numpy.matrix.sum

NumPy's implementation of 'sum' for matrices

scipy.sparse.dok_matrix.toarray

dok_matrix.**toarray**(*order=None*, *out=None*)
Return a dense ndarray representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

Returns

arr [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.dok_matrix.tobsr

dok_matrix.**tobsr**(*blocksize=None*, *copy=False*)
Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

scipy.sparse.dok_matrix.tocoo

dok_matrix.**tocoo**(*copy=False*)
Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.dok_matrix.tocsc

dok_matrix.**tocsc**(*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.dok_matrix.tocsr

dok_matrix.**tocsr**(*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.dok_matrix.todense

dok_matrix.**todense**(*order=None*, *out=None*)

Return a dense matrix representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out [ndarray, 2-D, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

scipy.sparse.dok_matrix.todia

dok_matrix.**todia**(*copy=False*)

Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.dok_matrix.todok

dok_matrix.**todok**(*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.dok_matrix.tolil

dok_matrix.**tolil**(*copy=False*)
Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.dok_matrix.transpose

dok_matrix.**transpose**(*axes=None*, *copy=False*)
Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

copy [bool, optional] Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [*self* with the dimensions reversed.]

See also:

numpy.matrix.transpose

NumPy's implementation of 'transpose' for matrices

scipy.sparse.dok_matrix.update

dok_matrix.**update**(*[E]*, ***F*) → None. Update D from dict/iterable E and F.
If E is present and has a .keys() method, then does: for k in E: D[k] = E[k] If E is present and lacks a .keys() method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]

scipy.sparse.dok_matrix.values

dok_matrix.**values**() → an object providing a view on D's values

__getitem__	

scipy.sparse.lil_matrix

class scipy.sparse.**lil_matrix**(*arg1*, *shape=None*, *dtype=None*, *copy=False*)
Row-based list of lists sparse matrix

This is a structure for constructing sparse matrices incrementally. Note that inserting a single item can take linear time in the worst case; to construct a matrix efficiently, make sure the items are pre-sorted by index, per row.

This can be instantiated in several ways:

lil_matrix(D)

with a dense matrix or rank-2 ndarray D

lil_matrix(S)

with another sparse matrix S (equivalent to S.tolil())

lil_matrix((M, N), [dtype])

to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Advantages of the LIL format

- supports flexible slicing
- changes to the matrix sparsity structure are efficient

Disadvantages of the LIL format

- arithmetic operations LIL + LIL are slow (consider CSR or CSC)
- slow column slicing (consider CSC)
- slow matrix vector products (consider CSR or CSC)

Intended Usage

- LIL is a convenient format for constructing sparse matrices
- once a matrix has been constructed, convert to CSR or CSC format for fast arithmetic and matrix vector operations
- consider using the COO format when constructing large matrices

Data Structure

- An array (`self.rows`) of rows, each of which is a sorted list of column indices of non-zero elements.
- The corresponding nonzero values are stored in similar fashion in `self.data`.

Attributes

dtype	[dtype] Data type of the matrix
shape	[2-tuple] Get shape of a matrix.
ndim	[int] Number of dimensions (this is always 2)
nnz	Number of stored values, including explicit zeros.
data	LIL format data array of the matrix
rows	LIL format row index array of the matrix

Methods

__len__()	

__mul__(other)	interpret other and call one of the following
asformat(format[, copy])	Return this matrix in the passed format.
asfptype()	Upcast matrix to a floating point format (if necessary)
astype(dtype[, casting, copy])	Cast the matrix elements to a specified type.
conj([copy])	Element-wise complex conjugation.
conjugate([copy])	Element-wise complex conjugation.
copy()	Returns a copy of this matrix.
count_nonzero()	Number of non-zero entries, equivalent to
diagonal([k])	Returns the kth diagonal of the matrix.
dot(other)	Ordinary dot product
getH()	Return the Hermitian transpose of this matrix.
get_shape()	Get shape of a matrix.
getcol(j)	Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
getformat()	Format of a matrix representation as a string.
getmaxprint()	Maximum number of elements to display when printed.
getnnz([axis])	Number of stored values, including explicit zeros.
getrow(i)	Returns a copy of the ‘i’th row.
getrowview(i)	Returns a view of the ‘i’th row (without copying).
maximum(other)	Element-wise maximum between this and another matrix.
mean([axis, dtype, out])	Compute the arithmetic mean along the specified axis.
minimum(other)	Element-wise minimum between this and another matrix.
multiply(other)	Point-wise multiplication by another matrix
nonzero()	nonzero indices
power(n[, dtype])	Element-wise power.
reshape(self, shape[, order, copy])	Gives a new shape to a sparse matrix without changing its data.
resize(*shape)	Resize the matrix in-place to dimensions given by `shape`
set_shape(shape)	See *reshape*.
setdiag(values[, k])	Set diagonal or off-diagonal elements of the array.
sum([axis, dtype, out])	Sum the matrix elements over a given axis.
toarray([order, out])	Return a dense ndarray representation of this matrix.
tobsr([blocksize, copy])	Convert this matrix to Block Sparse Row format.
tocoo([copy])	Convert this matrix to COOrdinate format.
tocsc([copy])	Convert this matrix to Compressed Sparse Column format.
tocsr([copy])	Convert this matrix to Compressed Sparse Row format.
todense([order, out])	Return a dense matrix representation of this matrix.
todia([copy])	Convert this matrix to sparse DIAgonal format.
todok([copy])	Convert this matrix to Dictionary Of Keys format.
tolil([copy])	Convert this matrix to List of Lists format.
transpose([axes, copy])	Reverses the dimensions of the sparse matrix.

scipy.sparse.lil_matrix.__len__

lil_matrix.**__len__**()

scipy.sparse.lil_matrix.__mul__

lil_matrix.**__mul__**(*other*)

interpret other and call one of the following

self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

scipy.sparse.lil_matrix.asformat

lil_matrix.**asformat**(*format*, *copy=False*)

Return this matrix in the passed format.

Parameters

format [{str, None}] The desired matrix format ("csr", "csc", "lil", "dok", "array", …) or None for no conversion.

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [This matrix in the passed format.]

scipy.sparse.lil_matrix.asfptype

lil_matrix.**asfptype**()

Upcast matrix to a floating point format (if necessary)

scipy.sparse.lil_matrix.astype

lil_matrix.**astype**(*dtype*, *casting='unsafe'*, *copy=True*)

Cast the matrix elements to a specified type.

Parameters

dtype [string or numpy dtype] Typecode or data-type to which to cast the data.

casting [{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.

copy [bool, optional] If `copy` is *False*, the result might share some memory with this matrix. If `copy` is *True*, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.lil_matrix.conj

lil_matrix.**conj**(*copy=True*)
Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.lil_matrix.conjugate

lil_matrix.**conjugate**(*copy=True*)
Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.lil_matrix.copy

lil_matrix.**copy**()
Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

scipy.sparse.lil_matrix.count_nonzero

lil_matrix.**count_nonzero**()
Number of non-zero entries, equivalent to

np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.lil_matrix.diagonal

lil_matrix.**diagonal**(*k=0*)
Returns the kth diagonal of the matrix.

Parameters

k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
New in version 1.0.

See also:

numpy.diagonal

Equivalent numpy function.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.lil_matrix.dot

lil_matrix.**dot**(*other*)
Ordinary dot product

Examples

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.lil_matrix.getH

lil_matrix.**getH**()
Return the Hermitian transpose of this matrix.

See also:

numpy.matrix.getH

NumPy's implementation of *getH* for matrices

scipy.sparse.lil_matrix.get_shape

lil_matrix.**get_shape**()
Get shape of a matrix.

scipy.sparse.lil_matrix.getcol

lil_matrix.**getcol**(*j*)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.lil_matrix.getformat

lil_matrix.**getformat**()
Format of a matrix representation as a string.

scipy.sparse.lil_matrix.getmaxprint

lil_matrix.**getmaxprint**()
Maximum number of elements to display when printed.

scipy.sparse.lil_matrix.getnnz

lil_matrix.**getnnz**(*axis=None*)
Number of stored values, including explicit zeros.

Parameters

axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:

count_nonzero

Number of non-zero entries

scipy.sparse.lil_matrix.getrow

lil_matrix.**getrow**(*i*)
Returns a copy of the ‘i’th row.

scipy.sparse.lil_matrix.getrowview

lil_matrix.**getrowview**(*i*)
Returns a view of the 'i'th row (without copying).

scipy.sparse.lil_matrix.maximum

lil_matrix.**maximum**(*other*)
Element-wise maximum between this and another matrix.

scipy.sparse.lil_matrix.mean

lil_matrix.**mean**(*axis=None*, *dtype=None*, *out=None*)
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., *axis = None*).

dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

m [np.matrix]

See also:

numpy.matrix.mean

NumPy's implementation of 'mean' for matrices

scipy.sparse.lil_matrix.minimum

lil_matrix.**minimum**(*other*)
Element-wise minimum between this and another matrix.

scipy.sparse.lil_matrix.multiply

lil_matrix.**multiply**(*other*)
Point-wise multiplication by another matrix

scipy.sparse.lil_matrix.nonzero

lil_matrix.**nonzero**()
nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.lil_matrix.power

lil_matrix.**power**(*n*, *dtype=None*)
Element-wise power.

scipy.sparse.lil_matrix.reshape

lil_matrix.**reshape**(*self*, *shape*, *order='C'*, *copy=False*)
Gives a new shape to a sparse matrix without changing its data.

Parameters

shape [length-2 tuple of ints] The new shape should be compatible with the original shape.
order [{'C', 'F'}, optional] Read the elements using this index order. 'C' means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. 'F' means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

reshaped_matrix
[sparse matrix] A sparse matrix with the given `shape`, not necessarily of the same format as the current object.

See also:

numpy.matrix.reshape

NumPy's implementation of 'reshape' for matrices

scipy.sparse.lil_matrix.resize

lil_matrix.**resize**(**shape*)
Resize the matrix in-place to dimensions given by `shape`

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

shape [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

scipy.sparse.lil_matrix.set_shape

lil_matrix.**set_shape**(*shape*)
See *reshape*.

scipy.sparse.lil_matrix.setdiag

lil_matrix.**setdiag**(*values*, *k=0*)
Set diagonal or off-diagonal elements of the array.

Parameters

values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

scipy.sparse.lil_matrix.sum

lil_matrix.**sum**(*axis=None*, *dtype=None*, *out=None*)
Sum the matrix elements over a given axis.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., *axis* = *None*).

dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

sum_along_axis
[np.matrix] A matrix with the same shape as *self*, with the specified axis removed.

See also:

numpy.matrix.sum

NumPy's implementation of 'sum' for matrices

scipy.sparse.lil_matrix.toarray

lil_matrix.**toarray**(*order=None*, *out=None*)
Return a dense ndarray representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

Returns

arr [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.lil_matrix.tobsr

lil_matrix.**tobsr**(*blocksize=None*, *copy=False*)
Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

scipy.sparse.lil_matrix.tocoo

lil_matrix.**tocoo**(*copy=False*)
Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.lil_matrix.tocsc

lil_matrix.**tocsc**(*copy=False*)
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.lil_matrix.tocsr

lil_matrix.**tocsr**(*copy=False*)
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.lil_matrix.todense

lil_matrix.**todense**(*order=None*, *out=None*)
Return a dense matrix representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out [ndarray, 2-D, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

scipy.sparse.lil_matrix.todia

lil_matrix.**todia**(*copy=False*)
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.lil_matrix.todok

lil_matrix.**todok**(*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.lil_matrix.tolil

lil_matrix.**tolil**(*copy=False*)

Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.lil_matrix.transpose

lil_matrix.**transpose**(*axes=None*, *copy=False*)

Reverses the dimensions of the sparse matrix.

Parameters

axes	[None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy	[bool, optional] Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p	[*self* with the dimensions reversed.]

See also:

numpy.matrix.transpose

NumPy's implementation of 'transpose' for matrices

__getitem__	

scipy.sparse.spmatrix

class scipy.sparse.**spmatrix**(*maxprint=50*)

This class provides a base class for all sparse matrices. It cannot be instantiated. Most of the work is provided by subclasses.

Attributes

nnz	Number of stored values, including explicit zeros.
shape	Get shape of a matrix.

Methods

__len__()	

__mul__(other)	interpret other and call one of the following
asformat(format[, copy])	Return this matrix in the passed format.
asfptype()	Upcast matrix to a floating point format (if necessary)
astype(dtype[, casting, copy])	Cast the matrix elements to a specified type.
conj([copy])	Element-wise complex conjugation.
conjugate([copy])	Element-wise complex conjugation.
copy()	Returns a copy of this matrix.
count_nonzero()	Number of non-zero entries, equivalent to
diagonal([k])	Returns the kth diagonal of the matrix.
dot(other)	Ordinary dot product
getH()	Return the Hermitian transpose of this matrix.
get_shape()	Get shape of a matrix.
getcol(j)	Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
getformat()	Format of a matrix representation as a string.
getmaxprint()	Maximum number of elements to display when printed.
getnnz([axis])	Number of stored values, including explicit zeros.
getrow(i)	Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
maximum(other)	Element-wise maximum between this and another matrix.
mean([axis, dtype, out])	Compute the arithmetic mean along the specified axis.
minimum(other)	Element-wise minimum between this and another matrix.
multiply(other)	Point-wise multiplication by another matrix
nonzero()	nonzero indices
power(n[, dtype])	Element-wise power.
reshape(self, shape[, order, copy])	Gives a new shape to a sparse matrix without changing its data.
resize(shape)	Resize the matrix in-place to dimensions given by `shape`
set_shape(shape)	See *reshape*.
setdiag(values[, k])	Set diagonal or off-diagonal elements of the array.
sum([axis, dtype, out])	Sum the matrix elements over a given axis.
toarray([order, out])	Return a dense ndarray representation of this matrix.
tobsr([blocksize, copy])	Convert this matrix to Block Sparse Row format.
tocoo([copy])	Convert this matrix to COOrdinate format.
tocsc([copy])	Convert this matrix to Compressed Sparse Column format.
tocsr([copy])	Convert this matrix to Compressed Sparse Row format.
todense([order, out])	Return a dense matrix representation of this matrix.
todia([copy])	Convert this matrix to sparse DIAgonal format.
todok([copy])	Convert this matrix to Dictionary Of Keys format.
tolil([copy])	Convert this matrix to List of Lists format.
transpose([axes, copy])	Reverses the dimensions of the sparse matrix.

scipy.sparse.spmatrix.__len__

spmatrix.**__len__**()

scipy.sparse.spmatrix.__mul__

spmatrix.**__mul__**(*other*)

interpret other and call one of the following

self._mul_scalar() self._mul_vector() self._mul_multivector() self._mul_sparse_matrix()

scipy.sparse.spmatrix.asformat

spmatrix.**asformat**(*format*, *copy=False*)

Return this matrix in the passed format.

Parameters

format [{str, None}] The desired matrix format ("csr", "csc", "lil", "dok", "array", …) or None for no conversion.

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [This matrix in the passed format.]

scipy.sparse.spmatrix.asfptype

spmatrix.**asfptype**()

Upcast matrix to a floating point format (if necessary)

scipy.sparse.spmatrix.astype

spmatrix.**astype**(*dtype*, *casting='unsafe'*, *copy=True*)

Cast the matrix elements to a specified type.

Parameters

dtype [string or numpy dtype] Typecode or data-type to which to cast the data.

casting [{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.

copy [bool, optional] If `copy` is *False*, the result might share some memory with this matrix. If `copy` is *True*, it is guaranteed that the result and this matrix do not share any memory.

scipy.sparse.spmatrix.conj

spmatrix.**conj**(*copy=True*)

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.spmatrix.conjugate

spmatrix.**conjugate**(*copy=True*)

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

Parameters

copy [bool, optional] If True, the result is guaranteed to not share data with self.

Returns

A [The element-wise complex conjugate.]

scipy.sparse.spmatrix.copy

spmatrix.**copy**()

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

scipy.sparse.spmatrix.count_nonzero

spmatrix.**count_nonzero**()

Number of non-zero entries, equivalent to

np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

scipy.sparse.spmatrix.diagonal

spmatrix.**diagonal**(*k=0*)
Returns the kth diagonal of the matrix.

Parameters

k [int, optional] Which diagonal to get, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
New in version 1.0.

See also:

numpy.diagonal

Equivalent numpy function.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

scipy.sparse.spmatrix.dot

spmatrix.**dot**(*other*)
Ordinary dot product

Examples

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

scipy.sparse.spmatrix.getH

spmatrix.**getH**()
Return the Hermitian transpose of this matrix.

See also:

numpy.matrix.getH

NumPy's implementation of *getH* for matrices

scipy.sparse.spmatrix.get_shape

spmatrix.**get_shape**()
Get shape of a matrix.

scipy.sparse.spmatrix.getcol

spmatrix.**getcol**(*j*)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

scipy.sparse.spmatrix.getformat

spmatrix.**getformat**()
Format of a matrix representation as a string.

scipy.sparse.spmatrix.getmaxprint

spmatrix.**getmaxprint**()
Maximum number of elements to display when printed.

scipy.sparse.spmatrix.getnnz

spmatrix.**getnnz**(*axis=None*)
Number of stored values, including explicit zeros.

Parameters

axis [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

See also:

count_nonzero

Number of non-zero entries

scipy.sparse.spmatrix.getrow

spmatrix.**getrow**(*i*)
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

scipy.sparse.spmatrix.maximum

spmatrix.**maximum**(*other*)
Element-wise maximum between this and another matrix.

scipy.sparse.spmatrix.mean

spmatrix.**mean**(*axis=None*, *dtype=None*, *out=None*)
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., *axis* = *None*).

dtype [data-type, optional] Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

m [np.matrix]

See also:

numpy.matrix.mean

NumPy's implementation of 'mean' for matrices

scipy.sparse.spmatrix.minimum

spmatrix.**minimum**(*other*)
Element-wise minimum between this and another matrix.

scipy.sparse.spmatrix.multiply

spmatrix.**multiply**(*other*)
Point-wise multiplication by another matrix

scipy.sparse.spmatrix.nonzero

spmatrix.**nonzero**()
nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

scipy.sparse.spmatrix.power

spmatrix.**power**(*n*, *dtype=None*)
Element-wise power.

scipy.sparse.spmatrix.reshape

spmatrix.**reshape**(*self*, *shape*, *order='C'*, *copy=False*)
Gives a new shape to a sparse matrix without changing its data.

Parameters

shape [length-2 tuple of ints] The new shape should be compatible with the original shape.
order [{'C', 'F'}, optional] Read the elements using this index order. 'C' means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. 'F' means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
copy [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

reshaped_matrix
[sparse matrix] A sparse matrix with the given `shape`, not necessarily of the same format as the current object.

See also:

numpy.matrix.reshape

NumPy's implementation of 'reshape' for matrices

scipy.sparse.spmatrix.resize

spmatrix.**resize**(*shape*)

Resize the matrix in-place to dimensions given by `shape`

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

Parameters

shape [(int, int)] number of rows and columns in the new matrix

Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In numpy, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

scipy.sparse.spmatrix.set_shape

spmatrix.**set_shape**(*shape*)

See *reshape*.

scipy.sparse.spmatrix.setdiag

spmatrix.**setdiag**(*values*, *k=0*)

Set diagonal or off-diagonal elements of the array.

Parameters

values [array_like] New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.

k [int, optional] Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

scipy.sparse.spmatrix.sum

spmatrix.**sum**(*axis=None*, *dtype=None*, *out=None*)

Sum the matrix elements over a given axis.

Parameters

axis [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., *axis* = *None*).

dtype [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.
New in version 0.18.0.

out [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
New in version 0.18.0.

Returns

sum_along_axis
[np.matrix] A matrix with the same shape as *self*, with the specified axis removed.

See also:

numpy.matrix.sum

NumPy's implementation of 'sum' for matrices

scipy.sparse.spmatrix.toarray

spmatrix.**toarray**(*order=None*, *out=None*)

Return a dense ndarray representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

Returns

arr [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

scipy.sparse.spmatrix.tobsr

spmatrix.**tobsr**(*blocksize=None*, *copy=False*)

Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

scipy.sparse.spmatrix.tocoo

spmatrix.**tocoo**(*copy=False*)

Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

scipy.sparse.spmatrix.tocsc

spmatrix.**tocsc**(*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

scipy.sparse.spmatrix.tocsr

spmatrix.**tocsr**(*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

scipy.sparse.spmatrix.todense

spmatrix.**todense**(*order=None*, *out=None*)

Return a dense matrix representation of this matrix.

Parameters

order [{'C', 'F'}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

out [ndarray, 2-D, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

arr [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

scipy.sparse.spmatrix.todia

spmatrix.**todia**(*copy=False*)

Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

scipy.sparse.spmatrix.todok

spmatrix.**todok**(*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

scipy.sparse.spmatrix.tolil

spmatrix.**tolil**(*copy=False*)

Convert this matrix to List of Lists format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

scipy.sparse.spmatrix.transpose

spmatrix.**transpose**(*axes=None*, *copy=False*)

Reverses the dimensions of the sparse matrix.

Parameters

axes [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

copy [bool, optional] Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p [*self* with the dimensions reversed.]

See also:

numpy.matrix.transpose

NumPy's implementation of 'transpose' for matrices

Functions

Building sparse matrices:

eye(m[, n, k, dtype, format])	Sparse matrix with ones on diagonal
identity(n[, dtype, format])	Identity matrix in sparse format
kron(A, B[, format])	kronecker product of sparse matrices A and B
kronsum(A, B[, format])	kronecker sum of sparse matrices A and B
diags(diagonals[, offsets, shape, format, dtype])	Construct a sparse matrix from diagonals.
spdiags(data, diags, m, n[, format])	Return a sparse matrix from diagonals.
block_diag(mats[, format, dtype])	Build a block diagonal sparse matrix from provided matrices.
tril(A[, k, format])	Return the lower triangular portion of a matrix in sparse format
triu(A[, k, format])	Return the upper triangular portion of a matrix in sparse format
bmat(blocks[, format, dtype])	Build a sparse matrix from sparse sub-blocks

continues on next page

Table 183 – continued from previous page

hstack(blocks[, format, dtype])	Stack sparse matrices horizontally (column wise)
vstack(blocks[, format, dtype])	Stack sparse matrices vertically (row wise)
rand(m, n[, density, format, dtype, …])	Generate a sparse matrix of the given shape and density with uniformly distributed values.
random(m, n[, density, format, dtype, …])	Generate a sparse matrix of the given shape and density with randomly distributed values.

scipy.sparse.eye

scipy.sparse.**eye**(*m*, *n=None*, *k=0*, *dtype=<class 'float'>*, *format=None*)

Sparse matrix with ones on diagonal

Returns a sparse (m x n) matrix where the kth diagonal is all ones and everything else is zeros.

Parameters

m	[int] Number of rows in the matrix.
n	[int, optional] Number of columns. Default: *m*.
k	[int, optional] Diagonal to place ones on. Default: 0 (main diagonal).
dtype	[dtype, optional] Data type of the matrix.
format	[str, optional] Sparse format of the result, e.g., format="csr", etc.

Examples

```
>>> from scipy import sparse
>>> sparse.eye(3).toarray()
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])
>>> sparse.eye(3, dtype=np.int8)
<3x3 sparse matrix of type '<class 'numpy.int8'>'
    with 3 stored elements (1 diagonals) in DIAgonal format>
```

scipy.sparse.identity

scipy.sparse.**identity**(*n*, *dtype='d'*, *format=None*)

Identity matrix in sparse format

Returns an identity matrix with shape (n,n) using a given sparse format and dtype.

Parameters

n	[int] Shape of the identity matrix.
dtype	[dtype, optional] Data type of the matrix
format	[str, optional] Sparse format of the result, e.g., format="csr", etc.

Examples

```
>>> from scipy.sparse import identity
>>> identity(3).toarray()
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])
>>> identity(3, dtype='int8', format='dia')
<3x3 sparse matrix of type '<class 'numpy.int8'>'
        with 3 stored elements (1 diagonals) in DIAgonal format>
```

scipy.sparse.kron

scipy.sparse.**kron**(*A*, *B*, *format=None*)

kronecker product of sparse matrices A and B

Parameters

A	[sparse or dense matrix] first matrix of the product
B	[sparse or dense matrix] second matrix of the product
format	[str, optional] format of the result (e.g. “csr”)

Returns

kronecker product in a sparse matrix format

Examples

```
>>> from scipy import sparse
>>> A = sparse.csr_matrix(np.array([[0, 2], [5, 0]]))
>>> B = sparse.csr_matrix(np.array([[1, 2], [3, 4]]))
>>> sparse.kron(A, B).toarray()
array([[ 0,  0,  2,  4],
       [ 0,  0,  6,  8],
       [ 5, 10,  0,  0],
       [15, 20,  0,  0]])
```

```
>>> sparse.kron(A, [[1, 2], [3, 4]]).toarray()
array([[ 0,  0,  2,  4],
       [ 0,  0,  6,  8],
       [ 5, 10,  0,  0],
       [15, 20,  0,  0]])
```

scipy.sparse.kronsum

scipy.sparse.**kronsum**(*A*, *B*, *format=None*)

kronecker sum of sparse matrices A and B

Kronecker sum of two sparse matrices is a sum of two Kronecker products kron(I_n,A) + kron(B,I_m) where A has shape (m,m) and B has shape (n,n) and I_m and I_n are identity matrices of shape (m,m) and (n,n), respectively.

Parameters

A	square matrix
B	square matrix
format	[str] format of the result (e.g. "csr")

Returns

kronecker sum in a sparse matrix format

scipy.sparse.diags

scipy.sparse.**diags**(*diagonals*, *offsets=0*, *shape=None*, *format=None*, *dtype=None*)

Construct a sparse matrix from diagonals.

Parameters

diagonals	[sequence of array_like] Sequence of arrays containing the matrix diagonals, corresponding to *offsets*.
offsets	[sequence of int or an int, optional] **Diagonals to set:** • k = 0 the main diagonal (default) • k > 0 the kth upper diagonal • k < 0 the kth lower diagonal
shape	[tuple of int, optional] Shape of the result. If omitted, a square matrix large enough to contain the diagonals is returned.
format	[{"dia", "csr", "csc", "lil", …}, optional] Matrix format of the result. By default (format=None) an appropriate sparse matrix format is returned. This choice is subject to change.
dtype	[dtype, optional] Data type of the matrix.

See also:

spdiags

construct matrix from diagonals

Notes

This function differs from *spdiags* in the way it handles off-diagonals.

The result from *diags* is the sparse equivalent of:

```
np.diag(diagonals[0], offsets[0])
+ ...
+ np.diag(diagonals[k], offsets[k])
```

Repeated diagonal offsets are disallowed.

New in version 0.11.

Examples

```
>>> from scipy.sparse import diags
>>> diagonals = [[1, 2, 3, 4], [1, 2, 3], [1, 2]]
>>> diags(diagonals, [0, -1, 2]).toarray()
array([[1, 0, 1, 0],
       [1, 2, 0, 2],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```

Broadcasting of scalars is supported (but shape needs to be specified):

```
>>> diags([1, -2, 1], [-1, 0, 1], shape=(4, 4)).toarray()
array([[-2.,  1.,  0.,  0.],
       [ 1., -2.,  1.,  0.],
       [ 0.,  1., -2.,  1.],
       [ 0.,  0.,  1., -2.]])
```

If only one diagonal is wanted (as in `numpy.diag`), the following works as well:

```
>>> diags([1, 2, 3], 1).toarray()
array([[ 0.,  1.,  0.,  0.],
       [ 0.,  0.,  2.,  0.],
       [ 0.,  0.,  0.,  3.],
       [ 0.,  0.,  0.,  0.]])
```

scipy.sparse.spdiags

scipy.sparse.**spdiags**(*data*, *diags*, *m*, *n*, *format=None*)

Return a sparse matrix from diagonals.

Parameters

data	[array_like] matrix diagonals stored row-wise
diags	[diagonals to set] • k = 0 the main diagonal • k > 0 the k-th upper diagonal • k < 0 the k-th lower diagonal
m, n	[int] shape of the result
format	[str, optional] Format of the result. By default (format=None) an appropriate sparse matrix format is returned. This choice is subject to change.

See also:

diags

more convenient form of this function

dia_matrix

the sparse DIAgonal format.

Examples

```
>>> from scipy.sparse import spdiags
>>> data = np.array([[1, 2, 3, 4], [1, 2, 3, 4], [1, 2, 3, 4]])
>>> diags = np.array([0, -1, 2])
>>> spdiags(data, diags, 4, 4).toarray()
array([[1, 0, 3, 0],
       [1, 2, 0, 4],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```

scipy.sparse.block_diag

scipy.sparse.**block_diag**(*mats*, *format=None*, *dtype=None*)

Build a block diagonal sparse matrix from provided matrices.

Parameters

mats [sequence of matrices] Input matrices.

format [str, optional] The sparse format of the result (e.g., "csr"). If not given, the matrix is returned in "coo" format.

dtype [dtype specifier, optional] The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

Returns

res [sparse matrix]

See also:

bmat, **diags**

Notes

New in version 0.11.0.

Examples

```
>>> from scipy.sparse import coo_matrix, block_diag
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> C = coo_matrix([[7]])
>>> block_diag((A, B, C)).toarray()
array([[1, 2, 0, 0],
       [3, 4, 0, 0],
       [0, 0, 5, 0],
       [0, 0, 6, 0],
       [0, 0, 0, 7]])
```

scipy.sparse.tril

scipy.sparse.**tril**(*A*, *k=0*, *format=None*)

Return the lower triangular portion of a matrix in sparse format

Returns the elements on or below the k-th diagonal of the matrix A.

- k = 0 corresponds to the main diagonal
- k > 0 is above the main diagonal
- k < 0 is below the main diagonal

Parameters

A	[dense or sparse matrix] Matrix whose lower trianglar portion is desired.
k	[integer] The top-most diagonal of the lower triangle.
format	[string] Sparse format of the result, e.g. format="csr", etc.

Returns

L	[sparse matrix] Lower triangular portion of A in sparse format.

See also:

triu

upper triangle in sparse format

Examples

```
>>> from scipy.sparse import csr_matrix, tril
>>> A = csr_matrix([[1, 2, 0, 0, 3], [4, 5, 0, 6, 7], [0, 0, 8, 9, 0]],
...                dtype='int32')
>>> A.toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> tril(A).toarray()
array([[1, 0, 0, 0, 0],
       [4, 5, 0, 0, 0],
       [0, 0, 8, 0, 0]])
>>> tril(A).nnz
4
>>> tril(A, k=1).toarray()
array([[1, 2, 0, 0, 0],
       [4, 5, 0, 0, 0],
       [0, 0, 8, 9, 0]])
>>> tril(A, k=-1).toarray()
array([[0, 0, 0, 0, 0],
       [4, 0, 0, 0, 0],
       [0, 0, 0, 0, 0]])
>>> tril(A, format='csc')
<3x5 sparse matrix of type '<class 'numpy.int32'>'
        with 4 stored elements in Compressed Sparse Column format>
```

scipy.sparse.triu

scipy.sparse.**triu**(*A*, *k=0*, *format=None*)

Return the upper triangular portion of a matrix in sparse format

Returns the elements on or above the k-th diagonal of the matrix A.

- k = 0 corresponds to the main diagonal
- k > 0 is above the main diagonal
- k < 0 is below the main diagonal

Parameters

A	[dense or sparse matrix] Matrix whose upper trianglar portion is desired.
k	[integer] The bottom-most diagonal of the upper triangle.
format	[string] Sparse format of the result, e.g. format="csr", etc.

Returns

L	[sparse matrix] Upper triangular portion of A in sparse format.

See also:

tril

lower triangle in sparse format

Examples

```
>>> from scipy.sparse import csr_matrix, triu
>>> A = csr_matrix([[1, 2, 0, 0, 3], [4, 5, 0, 6, 7], [0, 0, 8, 9, 0]],
...                dtype='int32')
>>> A.toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A).toarray()
array([[1, 2, 0, 0, 3],
       [0, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A).nnz
8
>>> triu(A, k=1).toarray()
array([[0, 2, 0, 0, 3],
       [0, 0, 0, 6, 7],
       [0, 0, 0, 9, 0]])
>>> triu(A, k=-1).toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A, format='csc')
<3x5 sparse matrix of type '<class 'numpy.int32'>'
        with 8 stored elements in Compressed Sparse Column format>
```

scipy.sparse.bmat

scipy.sparse.**bmat**(*blocks*, *format=None*, *dtype=None*)

Build a sparse matrix from sparse sub-blocks

Parameters

blocks [array_like] Grid of sparse matrices with compatible shapes. An entry of None implies an all-zero matrix.

format [{'bsr', 'coo', 'csc', 'csr', 'dia', 'dok', 'lil'}, optional] The sparse format of the result (e.g. "csr"). By default an appropriate sparse matrix format is returned. This choice is subject to change.

dtype [dtype, optional] The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

Returns

bmat [sparse matrix]

See also:

block_diag, **diags**

Examples

```
>>> from scipy.sparse import coo_matrix, bmat
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> C = coo_matrix([[7]])
>>> bmat([[A, B], [None, C]]).toarray()
array([[1, 2, 5],
       [3, 4, 6],
       [0, 0, 7]])
```

```
>>> bmat([[A, None], [None, C]]).toarray()
array([[1, 2, 0],
       [3, 4, 0],
       [0, 0, 7]])
```

scipy.sparse.hstack

scipy.sparse.**hstack**(*blocks*, *format=None*, *dtype=None*)

Stack sparse matrices horizontally (column wise)

Parameters

blocks sequence of sparse matrices with compatible shapes

format [str] sparse format of the result (e.g., "csr") by default an appropriate sparse matrix format is returned. This choice is subject to change.

dtype [dtype, optional] The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

See also:

vstack

stack sparse matrices vertically (row wise)

Examples

```
>>> from scipy.sparse import coo_matrix, hstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> hstack([A,B]).toarray()
array([[1, 2, 5],
       [3, 4, 6]])
```

scipy.sparse.vstack

scipy.sparse.**vstack**(*blocks*, *format=None*, *dtype=None*)

Stack sparse matrices vertically (row wise)

Parameters

blocks	sequence of sparse matrices with compatible shapes
format	[str, optional] sparse format of the result (e.g., "csr") by default an appropriate sparse matrix format is returned. This choice is subject to change.
dtype	[dtype, optional] The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

See also:

hstack

stack sparse matrices horizontally (column wise)

Examples

```
>>> from scipy.sparse import coo_matrix, vstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5, 6]])
>>> vstack([A, B]).toarray()
array([[1, 2],
       [3, 4],
       [5, 6]])
```

scipy.sparse.rand

scipy.sparse.**rand**(*m*, *n*, *density=0.01*, *format='coo'*, *dtype=None*, *random_state=None*)

Generate a sparse matrix of the given shape and density with uniformly distributed values.

Parameters

m, n	[int] shape of the matrix
density	[real, optional] density of the generated matrix: density equal to one means a full matrix, density of 0 means a matrix with no non-zero items.

format [str, optional] sparse matrix format.
dtype [dtype, optional] type of the returned matrix values.
random_state
[{None, int, numpy.random.Generator,]
numpy.random.RandomState}, optional
If *seed* is None (or *np.random*), the numpy.random.RandomState singleton is used. If *seed* is an int, a new RandomState instance is used, seeded with *seed*. If *seed* is already a Generator or RandomState instance then that instance is used.

Returns

res [sparse matrix]

See also:

scipy.sparse.random

Similar function that allows a user-specified random data source.

Notes

Only float types are supported for now.

Examples

```
>>> from scipy.sparse import rand
>>> matrix = rand(3, 4, density=0.25, format="csr", random_state=42)
>>> matrix
<3x4 sparse matrix of type '<class 'numpy.float64'>'
   with 3 stored elements in Compressed Sparse Row format>
>>> matrix.todense()
matrix([[0.05641158, 0.        , 0.        , 0.65088847],
        [0.        , 0.        , 0.        , 0.14286682],
        [0.        , 0.        , 0.        , 0.        ]])
```

scipy.sparse.random

scipy.sparse.**random**(*m*, *n*, *density=0.01*, *format='coo'*, *dtype=None*, *random_state=None*, *data_rvs=None*)

Generate a sparse matrix of the given shape and density with randomly distributed values.

Parameters

m, n [int] shape of the matrix
density [real, optional] density of the generated matrix: density equal to one means a full matrix, density of 0 means a matrix with no non-zero items.
format [str, optional] sparse matrix format.
dtype [dtype, optional] type of the returned matrix values.
random_state
[{None, int, numpy.random.Generator,]
numpy.random.RandomState}, optional

If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used. This random state will be used for sampling the sparsity structure, but not necessarily for sampling the values of the structurally nonzero entries of the matrix.

data_rvs [callable, optional] Samples a requested number of random values. This function should take a single argument specifying the length of the ndarray that it will return. The structurally nonzero entries of the sparse random matrix will be taken from the array sampled by this function. By default, uniform [0, 1) random values will be sampled using the same random state as is used for sampling the sparsity structure.

Returns

res [sparse matrix]

Notes

Only float types are supported for now.

Examples

```
>>> from scipy.sparse import random
>>> from scipy import stats
>>> from numpy.random import default_rng
>>> rng = default_rng()
>>> rvs = stats.poisson(25, loc=10).rvs
>>> S = random(3, 4, density=0.25, random_state=rng, data_rvs=rvs)
>>> S.A
array([[ 36.,   0.,  33.,   0.],   # random
       [  0.,   0.,   0.,   0.],
       [  0.,   0.,  36.,   0.]])
```

```
>>> from scipy.sparse import random
>>> from scipy.stats import rv_continuous
>>> class CustomDistribution(rv_continuous):
...     def _rvs(self,  size=None, random_state=None):
...         return random_state.standard_normal(size)
>>> X = CustomDistribution(seed=rng)
>>> Y = X()  # get a frozen version of the distribution
>>> S = random(3, 4, density=0.25, random_state=rng, data_rvs=Y.rvs)
>>> S.A
array([[ 0.        ,  0.        ,  0.        ,  0.        ],   # random
       [ 0.13569738,  1.9467163 , -0.81205367,  0.        ],
       [ 0.        ,  0.        ,  0.        ,  0.        ]])
```

Save and load sparse matrices:

save_npz(file, matrix[, compressed])	Save a sparse matrix to a file using `.npz` format.
load_npz(file)	Load a sparse matrix from a file using `.npz` format.

scipy.sparse.save_npz

scipy.sparse.**save_npz**(*file*, *matrix*, *compressed=True*)

Save a sparse matrix to a file using `.npz` format.

Parameters

file [str or file-like object] Either the file name (string) or an open file (file-like object) where the data will be saved. If file is a string, the `.npz` extension will be appended to the file name if it is not already there.

matrix: spmatrix (format: ``csc``, ``csr``, ``bsr``, ``dia`` or coo``)
The sparse matrix to save.

compressed
[bool, optional] Allow compressing the file. Default: True

See also:

scipy.sparse.load_npz

Load a sparse matrix from a file using `.npz` format.

numpy.savez

Save several arrays into a `.npz` archive.

numpy.savez_compressed

Save several arrays into a compressed `.npz` archive.

Examples

Store sparse matrix to disk, and load it again:

```
>>> import scipy.sparse
>>> sparse_matrix = scipy.sparse.csc_matrix(np.array([[0, 0, 3], [4, 0,␣
↪0]]))
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
   with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
```

```
>>> scipy.sparse.save_npz('/tmp/sparse_matrix.npz', sparse_matrix)
>>> sparse_matrix = scipy.sparse.load_npz('/tmp/sparse_matrix.npz')
```

```
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
   with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
```

scipy.sparse.load_npz

scipy.sparse.**load_npz**(*file*)

Load a sparse matrix from a file using `.npz` format.

Parameters

file [str or file-like object] Either the file name (string) or an open file (file-like object) where the data will be loaded.

Returns

result [csc_matrix, csr_matrix, bsr_matrix, dia_matrix or coo_matrix] A sparse matrix containing the loaded data.

Raises

IOError If the input file does not exist or cannot be read.

See also:

scipy.sparse.save_npz

Save a sparse matrix to a file using `.npz` format.

numpy.load

Load several arrays from a `.npz` archive.

Examples

Store sparse matrix to disk, and load it again:

```
>>> import scipy.sparse
>>> sparse_matrix = scipy.sparse.csc_matrix(np.array([[0, 0, 3], [4, 0,␣
↪0]]))
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
   with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
```

```
>>> scipy.sparse.save_npz('/tmp/sparse_matrix.npz', sparse_matrix)
>>> sparse_matrix = scipy.sparse.load_npz('/tmp/sparse_matrix.npz')
```

```
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
    with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
```

Sparse matrix tools:

find(A)	Return the indices and values of the nonzero elements of a matrix

scipy.sparse.find

scipy.sparse.**find**(*A*)

Return the indices and values of the nonzero elements of a matrix

Parameters

A [dense or sparse matrix] Matrix whose nonzero elements are desired.

Returns

(I,J,V) [tuple of arrays] I,J, and V contain the row indices, column indices, and values of the nonzero matrix entries.

Examples

```
>>> from scipy.sparse import csr_matrix, find
>>> A = csr_matrix([[7.0, 8.0, 0],[0, 0, 9.0]])
>>> find(A)
(array([0, 0, 1], dtype=int32), array([0, 1, 2], dtype=int32), array([ 7.,
↪  8.,  9.]))
```

Identifying sparse matrices:

issparse(x)	Is x of a sparse matrix type?
isspmatrix(x)	Is x of a sparse matrix type?
isspmatrix_csc(x)	Is x of csc_matrix type?
isspmatrix_csr(x)	Is x of csr_matrix type?
isspmatrix_bsr(x)	Is x of a bsr_matrix type?
isspmatrix_lil(x)	Is x of lil_matrix type?
isspmatrix_dok(x)	Is x of dok_matrix type?
isspmatrix_coo(x)	Is x of coo_matrix type?
isspmatrix_dia(x)	Is x of dia_matrix type?

scipy.sparse.issparse

scipy.sparse.**issparse**(*x*)

Is x of a sparse matrix type?

Parameters

x object to check for being a sparse matrix

Returns

bool True if x is a sparse matrix, False otherwise

Notes

issparse and isspmatrix are aliases for the same function.

Examples

```
>>> from scipy.sparse import csr_matrix, isspmatrix
>>> isspmatrix(csr_matrix([[5]]))
True
```

```
>>> from scipy.sparse import isspmatrix
>>> isspmatrix(5)
False
```

scipy.sparse.isspmatrix

scipy.sparse.**isspmatrix**(*x*)

Is x of a sparse matrix type?

Parameters

x object to check for being a sparse matrix

Returns

bool True if x is a sparse matrix, False otherwise

Notes

issparse and isspmatrix are aliases for the same function.

Examples

```
>>> from scipy.sparse import csr_matrix, isspmatrix
>>> isspmatrix(csr_matrix([[5]]))
True
```

```
>>> from scipy.sparse import isspmatrix
>>> isspmatrix(5)
False
```

scipy.sparse.isspmatrix_csc

scipy.sparse.**isspmatrix_csc**(*x*)

Is x of csc_matrix type?

Parameters

x object to check for being a csc matrix

Returns

bool True if x is a csc matrix, False otherwise

Examples

```
>>> from scipy.sparse import csc_matrix, isspmatrix_csc
>>> isspmatrix_csc(csc_matrix([[5]]))
True
```

```
>>> from scipy.sparse import csc_matrix, csr_matrix, isspmatrix_csc
>>> isspmatrix_csc(csr_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_csr

scipy.sparse.**isspmatrix_csr**(*x*)

Is x of csr_matrix type?

Parameters

x object to check for being a csr matrix

Returns

bool True if x is a csr matrix, False otherwise

Examples

```
>>> from scipy.sparse import csr_matrix, isspmatrix_csr
>>> isspmatrix_csr(csr_matrix([[5]]))
True
```

```
>>> from scipy.sparse import csc_matrix, csr_matrix, isspmatrix_csc
>>> isspmatrix_csr(csc_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_bsr

scipy.sparse.**isspmatrix_bsr**(*x*)

Is x of a bsr_matrix type?

Parameters

x object to check for being a bsr matrix

Returns

bool True if x is a bsr matrix, False otherwise

Examples

```
>>> from scipy.sparse import bsr_matrix, isspmatrix_bsr
>>> isspmatrix_bsr(bsr_matrix([[5]]))
True
```

```
>>> from scipy.sparse import bsr_matrix, csr_matrix, isspmatrix_bsr
>>> isspmatrix_bsr(csr_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_lil

scipy.sparse.**isspmatrix_lil**(*x*)

Is x of lil_matrix type?

Parameters

x object to check for being a lil matrix

Returns

bool True if x is a lil matrix, False otherwise

Examples

```
>>> from scipy.sparse import lil_matrix, isspmatrix_lil
>>> isspmatrix_lil(lil_matrix([[5]]))
True
```

```
>>> from scipy.sparse import lil_matrix, csr_matrix, isspmatrix_lil
>>> isspmatrix_lil(csr_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_dok

scipy.sparse.**isspmatrix_dok**(*x*)

Is x of dok_matrix type?

Parameters

x object to check for being a dok matrix

Returns

bool True if x is a dok matrix, False otherwise

Examples

```
>>> from scipy.sparse import dok_matrix, isspmatrix_dok
>>> isspmatrix_dok(dok_matrix([[5]]))
True
```

```
>>> from scipy.sparse import dok_matrix, csr_matrix, isspmatrix_dok
>>> isspmatrix_dok(csr_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_coo

scipy.sparse.**isspmatrix_coo**(*x*)

Is x of coo_matrix type?

Parameters

x object to check for being a coo matrix

Returns

bool True if x is a coo matrix, False otherwise

Examples

```
>>> from scipy.sparse import coo_matrix, isspmatrix_coo
>>> isspmatrix_coo(coo_matrix([[5]]))
True
```

```
>>> from scipy.sparse import coo_matrix, csr_matrix, isspmatrix_coo
>>> isspmatrix_coo(csr_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_dia

scipy.sparse.**isspmatrix_dia**(*x*)

Is x of dia_matrix type?

Parameters

x object to check for being a dia matrix

Returns

bool True if x is a dia matrix, False otherwise

Examples

```
>>> from scipy.sparse import dia_matrix, isspmatrix_dia
>>> isspmatrix_dia(dia_matrix([[5]]))
True
```

```
>>> from scipy.sparse import dia_matrix, csr_matrix, isspmatrix_dia
>>> isspmatrix_dia(csr_matrix([[5]]))
False
```

Usage information

There are seven available sparse matrix types:

1. csc_matrix: Compressed Sparse Column format
2. csr_matrix: Compressed Sparse Row format
3. bsr_matrix: Block Sparse Row format
4. lil_matrix: List of Lists format
5. dok_matrix: Dictionary of Keys format
6. coo_matrix: COOrdinate format (aka IJV, triplet format)
7. dia_matrix: DIAgonal format

To construct a matrix efficiently, use either dok_matrix or lil_matrix. The lil_matrix class supports basic slicing and fancy indexing with a similar syntax to NumPy arrays. As illustrated below, the COO format may also be used to efficiently construct matrices. Despite their similarity to NumPy arrays, it is **strongly discouraged** to use NumPy functions directly on these matrices because NumPy may not properly convert them for computations, leading to unexpected (and incorrect) results. If you do want to apply a NumPy function to these matrices, first check if SciPy has its own implementation for the given sparse matrix class, or **convert the sparse matrix to a NumPy array** (e.g., using the *toarray()* method of the class) first before applying the method.

To perform manipulations such as multiplication or inversion, first convert the matrix to either CSC or CSR format. The lil_matrix format is row-based, so conversion to CSR is efficient, whereas conversion to CSC is less so.

All conversions among the CSR, CSC, and COO formats are efficient, linear-time operations.

Matrix vector product

To do a vector product between a sparse matrix and a vector simply use the matrix *dot* method, as described in its docstring:

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

Warning: As of NumPy 1.7, *np.dot* is not aware of sparse matrices, therefore using it will result on unexpected results or errors. The corresponding dense array should be obtained first instead:

```
>>> np.dot(A.toarray(), v)
array([ 1, -3, -1], dtype=int64)
```

but then all the performance advantages would be lost.

The CSR format is specially suitable for fast matrix vector products.

Example 1

Construct a 1000x1000 lil_matrix and add some values to it:

```
>>> from scipy.sparse import lil_matrix
>>> from scipy.sparse.linalg import spsolve
>>> from numpy.linalg import solve, norm
>>> from numpy.random import rand
```

```
>>> A = lil_matrix((1000, 1000))
>>> A[0, :100] = rand(100)
>>> A[1, 100:200] = A[0, :100]
>>> A.setdiag(rand(1000))
```

Now convert it to CSR format and solve A x = b for x:

```
>>> A = A.tocsr()
>>> b = rand(1000)
>>> x = spsolve(A, b)
```

Convert it to a dense matrix and solve, and check that the result is the same:

```
>>> x_ = solve(A.toarray(), b)
```

Now we can compute norm of the error with:

```
>>> err = norm(x-x_)
>>> err < 1e-10
True
```

It should be small :)

Example 2

Construct a matrix in COO format:

```
>>> from scipy import sparse
>>> from numpy import array
>>> I = array([0,3,1,0])
>>> J = array([0,3,1,2])
>>> V = array([4,5,7,9])
>>> A = sparse.coo_matrix((V,(I,J)),shape=(4,4))
```

Notice that the indices do not need to be sorted.

Duplicate (i,j) entries are summed when converting to CSR or CSC.

```
>>> I = array([0,0,1,3,1,0,0])
>>> J = array([0,2,1,3,1,0,0])
>>> V = array([1,1,1,1,1,1,1])
>>> B = sparse.coo_matrix((V,(I,J)),shape=(4,4)).tocsr()
```

This is useful for constructing finite-element stiffness and mass matrices.

Further details

CSR column indices are not necessarily sorted. Likewise for CSC row indices. Use the .sorted_indices() and .sort_indices() methods when sorted indices are required (e.g., when passing data to other libraries).

3.3.24 Sparse linear algebra (`scipy.sparse.linalg`)

Abstract linear operators

LinearOperator(*args, **kwargs)	Common interface for performing matrix vector products
aslinearoperator(A)	Return A as a LinearOperator.

scipy.sparse.linalg.LinearOperator

class scipy.sparse.linalg.**LinearOperator**(**args*, ***kwargs*)

Common interface for performing matrix vector products

Many iterative methods (e.g. cg, gmres) do not need to know the individual entries of a matrix to solve a linear system A*x=b. Such solvers only require the computation of matrix vector products, A*v where v is a dense vector. This class serves as an abstract interface between iterative solvers and matrix-like objects.

To construct a concrete LinearOperator, either pass appropriate callables to the constructor of this class, or subclass it.

A subclass must implement either one of the methods `_matvec` and `_matmat`, and the attributes/properties `shape` (pair of integers) and `dtype` (may be None). It may call the `__init__` on this class to have these attributes validated. Implementing `_matvec` automatically implements `_matmat` (using a naive algorithm) and vice-versa.

Optionally, a subclass may implement `_rmatvec` or `_adjoint` to implement the Hermitian adjoint (conjugate transpose). As with `_matvec` and `_matmat`, implementing either `_rmatvec` or `_adjoint` implements the other automatically. Implementing `_adjoint` is preferable; `_rmatvec` is mostly there for backwards compatibility.

Parameters

shape	[tuple] Matrix dimensions (M, N).
matvec	[callable f(v)] Returns returns A * v.
rmatvec	[callable f(v)] Returns A^H * v, where A^H is the conjugate transpose of A.
matmat	[callable f(V)] Returns A * V, where V is a dense matrix with dimensions (N, K).
dtype	[dtype] Data type of the matrix.
rmatmat	[callable f(V)] Returns A^H * V, where V is a dense matrix with dimensions (M, K).

See also:

aslinearoperator

Construct LinearOperators

Notes

The user-defined matvec() function must properly handle the case where v has shape (N,) as well as the (N,1) case. The shape of the return type is handled internally by LinearOperator.

LinearOperator instances can also be multiplied, added with each other and exponentiated, all lazily: the result of these operations is always a new, composite LinearOperator, that defers linear operations to the original operators and combines the results.

More details regarding how to subclass a LinearOperator and several examples of concrete LinearOperator instances can be found in the external project PyLops.

Examples

```
>>> import numpy as np
>>> from scipy.sparse.linalg import LinearOperator
>>> def mv(v):
...     return np.array([2*v[0], 3*v[1]])
...
>>> A = LinearOperator((2,2), matvec=mv)
>>> A
<2x2 _CustomLinearOperator with dtype=float64>
>>> A.matvec(np.ones(2))
array([ 2.,  3.])
>>> A * np.ones(2)
array([ 2.,  3.])
```

Attributes

args [tuple] For linear operators describing products etc. of other linear operators, the operands of the binary operation.

ndim [int] Number of dimensions (this is always 2)

Methods

__call__(x)	Call self as a function.
adjoint()	Hermitian adjoint.
dot(x)	Matrix-matrix or matrix-vector multiplication.
matmat(X)	Matrix-matrix multiplication.
matvec(x)	Matrix-vector multiplication.
rmatmat(X)	Adjoint matrix-matrix multiplication.
rmatvec(x)	Adjoint matrix-vector multiplication.
transpose()	Transpose this linear operator.

scipy.sparse.linalg.LinearOperator.__call__

LinearOperator.**__call__**(*x*)
Call self as a function.

scipy.sparse.linalg.LinearOperator.adjoint

LinearOperator.**adjoint**()
Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated self.H instead of self.adjoint().

Returns

A_H [LinearOperator] Hermitian adjoint of self.

scipy.sparse.linalg.LinearOperator.dot

LinearOperator.**dot**(*x*)
Matrix-matrix or matrix-vector multiplication.

Parameters

x [array_like] 1-d or 2-d array, representing a vector or matrix.

Returns

Ax [array] 1-d or 2-d array (depending on the shape of x) that represents the result of applying this linear operator on x.

scipy.sparse.linalg.LinearOperator.matmat

LinearOperator.**matmat**(*X*)
Matrix-matrix multiplication.

Performs the operation y=A*X where A is an MxN linear operator and X dense N*K matrix or ndarray.

Parameters

X [{matrix, ndarray}] An array with shape (N,K).

Returns

Y [{matrix, ndarray}] A matrix or ndarray with shape (M,K) depending on the type of the X argument.

Notes

This matmat wraps any user-specified matmat routine or overridden _matmat method to ensure that y has the correct type.

scipy.sparse.linalg.LinearOperator.matvec

LinearOperator.**matvec**(*x*)

Matrix-vector multiplication.

Performs the operation y=A*x where A is an MxN linear operator and x is a column vector or 1-d array.

Parameters

x [{matrix, ndarray}] An array with shape (N,) or (N,1).

Returns

y [{matrix, ndarray}] A matrix or ndarray with shape (M,) or (M,1) depending on the type and shape of the x argument.

Notes

This matvec wraps the user-specified matvec routine or overridden _matvec method to ensure that y has the correct shape and type.

scipy.sparse.linalg.LinearOperator.rmatmat

LinearOperator.**rmatmat**(*X*)

Adjoint matrix-matrix multiplication.

Performs the operation y = A^H * x where A is an MxN linear operator and x is a column vector or 1-d array, or 2-d array. The default implementation defers to the adjoint.

Parameters

X [{matrix, ndarray}] A matrix or 2D array.

Returns

Y [{matrix, ndarray}] A matrix or 2D array depending on the type of the input.

Notes

This rmatmat wraps the user-specified rmatmat routine.

scipy.sparse.linalg.LinearOperator.rmatvec

LinearOperator.**rmatvec**(*x*)

Adjoint matrix-vector multiplication.

Performs the operation y = A^H * x where A is an MxN linear operator and x is a column vector or 1-d array.

Parameters

x [{matrix, ndarray}] An array with shape (M,) or (M,1).

Returns

y [{matrix, ndarray}] A matrix or ndarray with shape (N,) or (N,1) depending on the type and shape of the x argument.

Notes

This rmatvec wraps the user-specified rmatvec routine or overridden _rmatvec method to ensure that y has the correct shape and type.

scipy.sparse.linalg.LinearOperator.transpose

LinearOperator.**transpose**()

Transpose this linear operator.

Returns a LinearOperator that represents the transpose of this one. Can be abbreviated self.T instead of self.transpose().

__mul__	

scipy.sparse.linalg.aslinearoperator

scipy.sparse.linalg.**aslinearoperator**(*A*)

Return A as a LinearOperator.

'A' may be any of the following types:

- ndarray
- matrix
- sparse matrix (e.g. csr_matrix, lil_matrix, etc.)
- LinearOperator
- An object with .shape and .matvec attributes

See the LinearOperator documentation for additional information.

Notes

If 'A' has no .dtype attribute, the data type is determined by calling *LinearOperator.matvec* - set the .dtype attribute to prevent this call upon the linear operator creation.

Examples

```
>>> from scipy.sparse.linalg import aslinearoperator
>>> M = np.array([[1,2,3],[4,5,6]], dtype=np.int32)
>>> aslinearoperator(M)
<2x3 MatrixLinearOperator with dtype=int32>
```

Matrix Operations

inv(A)	Compute the inverse of a sparse matrix
expm(A)	Compute the matrix exponential using Pade approximation.
expm_multiply(A, B[, start, stop, num, endpoint])	Compute the action of the matrix exponential of A on B.

scipy.sparse.linalg.inv

scipy.sparse.linalg.**inv**(*A*)

Compute the inverse of a sparse matrix

Parameters

A [(M,M) ndarray or sparse matrix] square matrix to be inverted

Returns

Ainv [(M,M) ndarray or sparse matrix] inverse of *A*

Notes

This computes the sparse inverse of *A*. If the inverse of *A* is expected to be non-sparse, it will likely be faster to convert *A* to dense and use scipy.linalg.inv.

Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import inv
>>> A = csc_matrix([[1., 0.], [1., 2.]])
>>> Ainv = inv(A)
>>> Ainv
<2x2 sparse matrix of type '<class 'numpy.float64'>'
    with 3 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv)
<2x2 sparse matrix of type '<class 'numpy.float64'>'
    with 2 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv).todense()
```

(continues on next page)

(continued from previous page)

```
matrix([[ 1.,  0.],
        [ 0.,  1.]])
```

New in version 0.12.0.

scipy.sparse.linalg.expm

scipy.sparse.linalg.**expm**(*A*)

Compute the matrix exponential using Pade approximation.

Parameters

A [(M,M) array_like or sparse matrix] 2D Array or Matrix (sparse or dense) to be exponentiated

Returns

expA [(M,M) ndarray] Matrix exponential of *A*

Notes

This is algorithm (6.1) which is a simplification of algorithm (5.1).

New in version 0.12.0.

References

[1]

Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm
>>> A = csc_matrix([[1, 0, 0], [0, 2, 0], [0, 0, 3]])
>>> A.todense()
matrix([[1, 0, 0],
        [0, 2, 0],
        [0, 0, 3]], dtype=int64)
>>> Aexp = expm(A)
>>> Aexp
<3x3 sparse matrix of type '<class 'numpy.float64'>'
    with 3 stored elements in Compressed Sparse Column format>
>>> Aexp.todense()
matrix([[  2.71828183,   0.        ,   0.        ],
        [  0.        ,   7.3890561 ,   0.        ],
        [  0.        ,   0.        ,  20.08553692]])
```

scipy.sparse.linalg.expm_multiply

scipy.sparse.linalg.**expm_multiply**(*A*, *B*, *start=None*, *stop=None*, *num=None*, *endpoint=None*)

Compute the action of the matrix exponential of A on B.

Parameters

A	[transposable linear operator] The operator whose exponential is of interest.
B	[ndarray] The matrix or vector to be multiplied by the matrix exponential of A.
start	[scalar, optional] The starting time point of the sequence.
stop	[scalar, optional] The end time point of the sequence, unless *endpoint* is set to False. In that case, the sequence consists of all but the last of `num + 1` evenly spaced time points, so that *stop* is excluded. Note that the step size changes when *endpoint* is False.
num	[int, optional] Number of time points to use.
endpoint	[bool, optional] If True, *stop* is the last time point. Otherwise, it is not included.

Returns

expm_A_B
: [ndarray] The result of the action $e^{t_k A} B$.

Notes

The optional arguments defining the sequence of evenly spaced time points are compatible with the arguments of `numpy.linspace`.

The output ndarray shape is somewhat complicated so I explain it here. The ndim of the output could be either 1, 2, or 3. It would be 1 if you are computing the expm action on a single vector at a single time point. It would be 2 if you are computing the expm action on a vector at multiple time points, or if you are computing the expm action on a matrix at a single time point. It would be 3 if you want the action on a matrix with multiple columns at multiple time points. If multiple time points are requested, expm_A_B[0] will always be the action of the expm at the first time point, regardless of whether the action is on a vector or a matrix.

Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm, expm_multiply
>>> A = csc_matrix([[1, 0], [0, 1]])
>>> A.todense()
matrix([[1, 0],
        [0, 1]], dtype=int64)
>>> B = np.array([np.exp(-1.), np.exp(-2.)])
>>> B
array([ 0.36787944,  0.13533528])
>>> expm_multiply(A, B, start=1, stop=2, num=3, endpoint=True)
array([[ 1.        ,  0.36787944],
       [ 1.64872127,  0.60653066],
       [ 2.71828183,  1.        ]])
>>> expm(A).dot(B)                  # Verify 1st timestep
```

(continues on next page)

(continued from previous page)

```
array([ 1.        ,  0.36787944])
>>> expm(1.5*A).dot(B)               # Verify 2nd timestep
array([ 1.64872127,  0.60653066])
>>> expm(2*A).dot(B)                 # Verify 3rd timestep
array([ 2.71828183,  1.        ])
```

Matrix norms

norm(x[, ord, axis])	Norm of a sparse matrix
onenormest(A[, t, itmax, compute_v, compute_w])	Compute a lower bound of the 1-norm of a sparse matrix.

scipy.sparse.linalg.norm

scipy.sparse.linalg.**norm**(*x*, *ord=None*, *axis=None*)

Norm of a sparse matrix

This function is able to return one of seven different matrix norms, depending on the value of the ord parameter.

Parameters

x [a sparse matrix] Input sparse matrix.

ord [{non-zero int, inf, -inf, 'fro'}, optional] Order of the norm (see table under Notes). inf means numpy's *inf* object.

axis [{int, 2-tuple of ints, None}, optional] If *axis* is an integer, it specifies the axis of *x* along which to compute the vector norms. If *axis* is a 2-tuple, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed. If *axis* is None then either a vector norm (when *x* is 1-D) or a matrix norm (when *x* is 2-D) is returned.

Returns

n [float or ndarray]

Notes

Some of the ord are not implemented because some associated functions like, _multi_svd_norm, are not yet available for sparse matrix.

This docstring is modified based on numpy.linalg.norm. https://github.com/numpy/numpy/blob/master/numpy/linalg/linalg.py

The following norms can be calculated:

ord	norm for sparse matrices
None	Frobenius norm
'fro'	Frobenius norm
inf	max(sum(abs(x), axis=1))
-inf	min(sum(abs(x), axis=1))
0	abs(x).sum(axis=axis)
1	max(sum(abs(x), axis=0))
-1	min(sum(abs(x), axis=0))
2	Not implemented
-2	Not implemented
other	Not implemented

The Frobenius norm is given by [1]:

$$||A||_F = [\sum_{i,j} abs(a_{i,j})^2]^{1/2}$$

References

[1]

Examples

```
>>> from scipy.sparse import *
>>> import numpy as np
>>> from scipy.sparse.linalg import norm
>>> a = np.arange(9) - 4
>>> a
array([-4, -3, -2, -1, 0, 1, 2, 3, 4])
>>> b = a.reshape((3, 3))
>>> b
array([[-4, -3, -2],
       [-1, 0, 1],
       [ 2, 3, 4]])
```

```
>>> b = csr_matrix(b)
>>> norm(b)
7.745966692414834
>>> norm(b, 'fro')
7.745966692414834
>>> norm(b, np.inf)
9
>>> norm(b, -np.inf)
2
>>> norm(b, 1)
7
>>> norm(b, -1)
6
```

scipy.sparse.linalg.onenormest

scipy.sparse.linalg.**onenormest**(*A*, *t=2*, *itmax=5*, *compute_v=False*, *compute_w=False*)

Compute a lower bound of the 1-norm of a sparse matrix.

Parameters

A [ndarray or other linear operator] A linear operator that can be transposed and that can produce matrix products.

t [int, optional] A positive parameter controlling the tradeoff between accuracy versus time and memory usage. Larger values take longer and use more memory but give more accurate output.

itmax [int, optional] Use at most this many iterations.

compute_v [bool, optional] Request a norm-maximizing linear operator input vector if True.

compute_w [bool, optional] Request a norm-maximizing linear operator output vector if True.

Returns

est	[float] An underestimate of the 1-norm of the sparse matrix.
v	[ndarray, optional] The vector such that ||Av||_1 == est*||v||_1. It can be thought of as an input to the linear operator that gives an output with particularly large norm.
w	[ndarray, optional] The vector Av which has relatively large 1-norm. It can be thought of as an output of the linear operator that is relatively large in norm compared to the input.

Notes

This is algorithm 2.4 of [1].

In [2] it is described as follows. "This algorithm typically requires the evaluation of about 4t matrix-vector products and almost invariably produces a norm estimate (which is, in fact, a lower bound on the norm) correct to within a factor 3."

New in version 0.13.0.

[1], [2]

Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import onenormest
>>> A = csc_matrix([[1., 0., 0.], [5., 8., 2.], [0., -1., 0.]],␣
↪dtype=float)
>>> A.todense()
matrix([[ 1.,  0.,  0.],
        [ 5.,  8.,  2.],
        [ 0., -1.,  0.]])
>>> onenormest(A)
9.0
>>> np.linalg.norm(A.todense(), ord=1)
9.0
```

Solving linear problems

Direct methods for linear equation systems:

spsolve(A, b[, permc_spec, use_umfpack])	Solve the sparse linear system Ax=b, where b may be a vector or a matrix.
spsolve_triangular(A, b[, lower, …])	Solve the equation `A x = b` for *x*, assuming A is a triangular matrix.
factorized(A)	Return a function for solving a sparse linear system, with A pre-factorized.
MatrixRankWarning	
use_solver(**kwargs)	Select default sparse direct solver to be used.

scipy.sparse.linalg.spsolve

scipy.sparse.linalg.**spsolve**(*A*, *b*, *permc_spec=None*, *use_umfpack=True*)

Solve the sparse linear system Ax=b, where b may be a vector or a matrix.

Parameters

A [ndarray or sparse matrix] The square matrix A will be converted into CSC or CSR form

b [ndarray or sparse matrix] The matrix or vector representing the right hand side of the equation. If a vector, b.shape must be (n,) or (n, 1).

permc_spec [str, optional] How to permute the columns of the matrix for sparsity preservation. (default: 'COLAMD')

- NATURAL: natural ordering.
- MMD_ATA: minimum degree ordering on the structure of A^T A.
- MMD_AT_PLUS_A: minimum degree ordering on the structure of A^T+A.
- COLAMD: approximate minimum degree column ordering

use_umfpack [bool, optional] if True (default) then use umfpack for the solution. This is only referenced if b is a vector and scikit-umfpack is installed.

Returns

x [ndarray or sparse matrix] the solution of the sparse linear equation. If b is a vector, then x is a vector of size A.shape[1] If b is a matrix, then x is a matrix of size (A.shape[1], b.shape[1])

Notes

For solving the matrix expression AX = B, this solver assumes the resulting matrix X is sparse, as is often the case for very sparse inputs. If the resulting X is dense, the construction of this sparse result will be relatively expensive. In that case, consider converting A to a dense matrix and using scipy.linalg.solve or its variants.

Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spsolve
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> B = csc_matrix([[2, 0], [-1, 0], [2, 0]], dtype=float)
>>> x = spsolve(A, B)
>>> np.allclose(A.dot(x).todense(), B.todense())
True
```

scipy.sparse.linalg.spsolve_triangular

scipy.sparse.linalg.**spsolve_triangular**(*A*, *b*, *lower=True*, *overwrite_A=False*, *overwrite_b=False*, *unit_diagonal=False*)

Solve the equation `A x = b` for *x*, assuming A is a triangular matrix.

Parameters

A [(M, M) sparse matrix] A sparse square triangular matrix. Should be in CSR format.

b [(M,) or (M, N) array_like] Right-hand side matrix in `A x = b`

lower [bool, optional] Whether *A* is a lower or upper triangular matrix. Default is lower triangular matrix.

overwrite_A
: [bool, optional] Allow changing *A*. The indices of *A* are going to be sorted and zero entries are going to be removed. Enabling gives a performance gain. Default is False.

overwrite_b
: [bool, optional] Allow overwriting data in *b*. Enabling gives a performance gain. Default is False. If *overwrite_b* is True, it should be ensured that *b* has an appropriate dtype to be able to store the result.

unit_diagonal
: [bool, optional] If True, diagonal elements of *a* are assumed to be 1 and will not be referenced.
New in version 1.4.0.

Returns

x
: [(M,) or (M, N) ndarray] Solution to the system `A x = b`. Shape of return matches shape of *b*.

Raises

LinAlgError
: If *A* is singular or not triangular.

ValueError
: If shape of *A* or shape of *b* do not match the requirements.

Notes

New in version 0.19.0.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.linalg import spsolve_triangular
>>> A = csr_matrix([[3, 0, 0], [1, -1, 0], [2, 0, 1]], dtype=float)
>>> B = np.array([[2, 0], [-1, 0], [2, 0]], dtype=float)
>>> x = spsolve_triangular(A, B)
>>> np.allclose(A.dot(x), B)
True
```

scipy.sparse.linalg.factorized

scipy.sparse.linalg.**factorized**(*A*)
Return a function for solving a sparse linear system, with A pre-factorized.

Parameters

A
: [(N, N) array_like] Input.

Returns

solve
: [callable] To solve the linear system of equations given in *A*, the *solve* callable should be passed an ndarray of shape (N,).

Examples

```
>>> from scipy.sparse.linalg import factorized
>>> A = np.array([[ 3. ,  2. , -1. ],
...               [ 2. , -2. ,  4. ],
...               [-1. ,  0.5, -1. ]])
>>> solve = factorized(A) # Makes LU decomposition.
>>> rhs1 = np.array([1, -2, 0])
>>> solve(rhs1) # Uses the LU factors.
array([ 1., -2., -2.])
```

scipy.sparse.linalg.MatrixRankWarning

exception scipy.sparse.linalg.**MatrixRankWarning**

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

scipy.sparse.linalg.use_solver

scipy.sparse.linalg.**use_solver**(***kwargs*)
Select default sparse direct solver to be used.

Parameters

useUmfpack
[bool, optional] Use UMFPACK over SuperLU. Has effect only if scikits.umfpack is installed. Default: True

assumeSortedIndices
[bool, optional] Allow UMFPACK to skip the step of sorting indices for a CSR/CSC matrix. Has effect only if useUmfpack is True and scikits.umfpack is installed. Default: False

Notes

The default sparse solver is umfpack when available (scikits.umfpack is installed). This can be changed by passing useUmfpack = False, which then causes the always present SuperLU based solver to be used.

Umfpack requires a CSR/CSC matrix to have sorted column/row indices. If sure that the matrix fulfills this, pass `assumeSortedIndices=True` to gain some speed.

Iterative methods for linear equation systems:

bicg(A, b[, x0, tol, maxiter, M, callback, atol])	Use BIConjugate Gradient iteration to solve `Ax = b`.
bicgstab(A, b[, x0, tol, maxiter, M, …])	Use BIConjugate Gradient STABilized iteration to solve `Ax = b`.
cg(A, b[, x0, tol, maxiter, M, callback, atol])	Use Conjugate Gradient iteration to solve `Ax = b`.
cgs(A, b[, x0, tol, maxiter, M, callback, atol])	Use Conjugate Gradient Squared iteration to solve `Ax = b`.
gmres(A, b[, x0, tol, restart, maxiter, M, …])	Use Generalized Minimal RESidual iteration to solve `Ax = b`.
lgmres(A, b[, x0, tol, maxiter, M, …])	Solve a matrix equation using the LGMRES algorithm.
minres(A, b[, x0, shift, tol, maxiter, M, …])	Use MINimum RESidual iteration to solve Ax=b
qmr(A, b[, x0, tol, maxiter, M1, M2, …])	Use Quasi-Minimal Residual iteration to solve `Ax = b`.

continues on next page

Table 194 – continued from previous page

gcrotmk(A, b[, x0, tol, maxiter, M, …])	Solve a matrix equation using flexible GCROT(m,k) algorithm.

scipy.sparse.linalg.bicg

scipy.sparse.linalg.**bicg**(*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=None*, *M=None*, *callback=None*, *atol=None*)

Use BIConjugate Gradient iteration to solve `Ax = b`.

Parameters

A [{sparse matrix, dense matrix, LinearOperator}] The real or complex N-by-N matrix of the linear system. Alternatively, `A` can be a linear operator which can produce `Ax` and `A^T x` using, e.g., `scipy.sparse.linalg.LinearOperator`.

b [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

Returns

x [{array, matrix}] The converged solution.

info [integer]
Provides convergence information:
0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

Other Parameters

x0 [{array, matrix}] Starting guess for the solution.

tol, atol [float, optional] Tolerances for convergence, `norm(residual) <= max(tol*norm(b), atol)`. The default for `atol` is `'legacy'`, which emulates a different legacy behavior.

> **Warning:** The default value for *atol* will be changed in a future release. For future compatibility, specify *atol* explicitly.

maxiter [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

M [{sparse matrix, dense matrix, LinearOperator}] Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

callback [function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import bicg
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = bicg(A, b)
>>> print(exitCode)            # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

scipy.sparse.linalg.bicgstab

scipy.sparse.linalg.**bicgstab**(*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=None*, *M=None*, *callback=None*, *atol=None*)

Use BIConjugate Gradient STABilized iteration to solve `Ax = b`.

Parameters

A [{sparse matrix, dense matrix, LinearOperator}] The real or complex N-by-N matrix of the linear system. Alternatively, `A` can be a linear operator which can produce `Ax` using, e.g., `scipy.sparse.linalg.LinearOperator`.

b [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

Returns

x [{array, matrix}] The converged solution.

info [integer]
Provides convergence information:
0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

Other Parameters

x0 [{array, matrix}] Starting guess for the solution.

tol, atol [float, optional] Tolerances for convergence, `norm(residual) <= max(tol*norm(b), atol)`. The default for `atol` is `'legacy'`, which emulates a different legacy behavior.

> **Warning:** The default value for *atol* will be changed in a future release. For future compatibility, specify *atol* explicitly.

maxiter [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

M [{sparse matrix, dense matrix, LinearOperator}] Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

callback [function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

scipy.sparse.linalg.cg

scipy.sparse.linalg.**cg**(*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=None*, *M=None*, *callback=None*, *atol=None*)

Use Conjugate Gradient iteration to solve `Ax = b`.

Parameters

A [{sparse matrix, dense matrix, LinearOperator}] The real or complex N-by-N matrix of the linear system. `A` must represent a hermitian, positive definite matrix. Alternatively, `A` can be a linear operator which can produce `Ax` using, e.g., `scipy.sparse.linalg.LinearOperator`.

b [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

Returns

x [{array, matrix}] The converged solution.

info [integer]

Provides convergence information:
0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

Other Parameters

x0 [{array, matrix}] Starting guess for the solution.

tol, atol [float, optional] Tolerances for convergence, `norm(residual) <= max(tol*norm(b), atol)`. The default for `atol` is `'legacy'`, which emulates a different legacy behavior.

> **Warning:** The default value for *atol* will be changed in a future release. For future compatibility, specify *atol* explicitly.

maxiter [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

M [{sparse matrix, dense matrix, LinearOperator}] Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

callback [function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

scipy.sparse.linalg.cgs

`scipy.sparse.linalg.`**`cgs`**(*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=None*, *M=None*, *callback=None*, *atol=None*)

Use Conjugate Gradient Squared iteration to solve `Ax = b`.

Parameters

A [{sparse matrix, dense matrix, LinearOperator}] The real-valued N-by-N matrix of the linear system. Alternatively, `A` can be a linear operator which can produce `Ax` using, e.g., `scipy.sparse.linalg.LinearOperator`.

b [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

Returns

x [{array, matrix}] The converged solution.

info [integer]
Provides convergence information:
0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

Other Parameters

x0 [{array, matrix}] Starting guess for the solution.

tol, atol [float, optional] Tolerances for convergence, `norm(residual) <= max(tol*norm(b), atol)`. The default for `atol` is `'legacy'`, which emulates a different legacy behavior.

> **Warning:** The default value for *atol* will be changed in a future release. For future compatibility, specify *atol* explicitly.

maxiter [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

M [{sparse matrix, dense matrix, LinearOperator}] Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

callback [function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

scipy.sparse.linalg.gmres

scipy.sparse.linalg.**gmres**(*A*, *b*, *x0=None*, *tol=1e-05*, *restart=None*, *maxiter=None*, *M=None*, *callback=None*, *restrt=None*, *atol=None*, *callback_type=None*)

Use Generalized Minimal RESidual iteration to solve `Ax = b`.

Parameters

A [{sparse matrix, dense matrix, LinearOperator}] The real or complex N-by-N matrix of the linear system. Alternatively, `A` can be a linear operator which can produce `Ax` using, e.g., `scipy.sparse.linalg.LinearOperator`.

b [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

Returns

x [{array, matrix}] The converged solution.

info [int]
Provides convergence information:

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations
- <0 : illegal input or breakdown

Other Parameters

x0 [{array, matrix}] Starting guess for the solution (a vector of zeros by default).

tol, atol [float, optional] Tolerances for convergence, `norm(residual) <= max(tol*norm(b), atol)`. The default for `atol` is `'legacy'`, which emulates a different legacy behavior.

> **Warning:** The default value for *atol* will be changed in a future release. For future compatibility, specify *atol* explicitly.

restart [int, optional] Number of iterations between restarts. Larger values increase iteration cost, but may be necessary for convergence. Default is 20.

maxiter [int, optional] Maximum number of iterations (restart cycles). Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

M [{sparse matrix, dense matrix, LinearOperator}] Inverse of the preconditioner of A. M should approximate the inverse of A and be easy to solve for (see Notes). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance. By default, no preconditioner is used.

callback [function] User-supplied function to call after each iteration. It is called as *callback(args)*, where *args* are selected by *callback_type*.

callback_type
[{'x', 'pr_norm', 'legacy'}, optional]
Callback function argument requested:

- `x`: current iterate (ndarray), called on every restart
- `pr_norm`: relative (preconditioned) residual norm (float), called on every inner iteration

- `legacy` (default): same as `pr_norm`, but also changes the meaning of 'maxiter' to count inner iterations instead of restart cycles.

restrt [int, optional] DEPRECATED - use *restart* instead.

See also:

`LinearOperator`

Notes

A preconditioner, P, is chosen such that P is close to A but easy to solve for. The preconditioner parameter required by this routine is `M = P^-1`. The inverse should preferably not be calculated explicitly. Rather, use the following template to produce M:

```
# Construct a linear operator that computes P^-1 * x.
import scipy.sparse.linalg as spla
M_x = lambda x: spla.spsolve(P, x)
M = spla.LinearOperator((n, n), M_x)
```

Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import gmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = gmres(A, b)
>>> print(exitCode)            # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

scipy.sparse.linalg.lgmres

scipy.sparse.linalg.**lgmres**(*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=1000*, *M=None*, *callback=None*, *inner_m=30*, *outer_k=3*, *outer_v=None*, *store_outer_Av=True*, *prepend_outer_v=False*, *atol=None*)

Solve a matrix equation using the LGMRES algorithm.

The LGMRES algorithm [1] [2] is designed to avoid some problems in the convergence in restarted GMRES, and often converges in fewer iterations.

Parameters

A [{sparse matrix, dense matrix, LinearOperator}] The real or complex N-by-N matrix of the linear system. Alternatively, `A` can be a linear operator which can produce `Ax` using, e.g., `scipy.sparse.linalg.LinearOperator`.

b [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

x0 [{array, matrix}] Starting guess for the solution.

tol, atol [float, optional] Tolerances for convergence, `norm(residual) <= max(tol*norm(b), atol)`. The default for `atol` is *tol*.

> **Warning:** The default value for *atol* will be changed in a future release. For future compatibility, specify *atol* explicitly.

maxiter [int, optional] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

M [{sparse matrix, dense matrix, LinearOperator}, optional] Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

callback [function, optional] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

inner_m [int, optional] Number of inner GMRES iterations per each outer iteration.

outer_k [int, optional] Number of vectors to carry between inner GMRES iterations. According to [1], good values are in the range of 1…3. However, note that if you want to use the additional vectors to accelerate solving multiple similar problems, larger values may be beneficial.

outer_v [list of tuples, optional] List containing tuples `(v, Av)` of vectors and corresponding matrix-vector products, used to augment the Krylov subspace, and carried between inner GMRES iterations. The element `Av` can be *None* if the matrix-vector product should be re-evaluated. This parameter is modified in-place by `lgmres`, and can be used to pass "guess" vectors in and out of the algorithm when solving similar problems.

store_outer_Av [bool, optional] Whether LGMRES should store also A*v in addition to vectors *v* in the *outer_v* list. Default is True.

prepend_outer_v [bool, optional] Whether to put outer_v augmentation vectors before Krylov iterates. In standard LGMRES, prepend_outer_v=False.

Returns

x [array or matrix] The converged solution.

info [int] Provides convergence information:

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations
- <0 : illegal input or breakdown

Notes

The LGMRES algorithm [1] [2] is designed to avoid the slowing of convergence in restarted GMRES, due to alternating residual vectors. Typically, it often outperforms GMRES(m) of comparable memory requirements by some measure, or at least is not much worse.

Another advantage in this algorithm is that you can supply it with 'guess' vectors in the *outer_v* argument that augment the Krylov subspace. If the solution lies close to the span of these vectors, the algorithm converges faster. This can be useful if several very similar matrices need to be inverted one after another, such as in Newton-Krylov iteration where the Jacobian matrix often changes little in the nonlinear steps.

Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lgmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = lgmres(A, b)
>>> print(exitCode)            # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

scipy.sparse.linalg.minres

scipy.sparse.linalg.**minres**(*A*, *b*, *x0=None*, *shift=0.0*, *tol=1e-05*, *maxiter=None*, *M=None*, *callback=None*, *show=False*, *check=False*)

Use MINimum RESidual iteration to solve Ax=b

MINRES minimizes norm(A*x - b) for a real symmetric matrix A. Unlike the Conjugate Gradient method, A can be indefinite or singular.

If shift != 0 then the method solves (A - shift*I)x = b

Parameters

A [{sparse matrix, dense matrix, LinearOperator}] The real symmetric N-by-N matrix of the linear system Alternatively, `A` can be a linear operator which can produce `Ax` using, e.g., `scipy.sparse.linalg.LinearOperator`.

b [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

Returns

x [{array, matrix}] The converged solution.

info [integer]
Provides convergence information:
0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

Other Parameters

x0 [{array, matrix}] Starting guess for the solution.

tol [float] Tolerance to achieve. The algorithm terminates when the relative residual is below *tol*.

maxiter [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

M [{sparse matrix, dense matrix, LinearOperator}] Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

callback [function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

```
>>> import numpy as np
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import minres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> A = A + A.T
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = minres(A, b)
>>> print(exitCode)            # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

scipy.sparse.linalg.qmr

scipy.sparse.linalg.**qmr**(*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=None*, *M1=None*, *M2=None*, *callback=None*, *atol=None*)

Use Quasi-Minimal Residual iteration to solve `Ax = b`.

Parameters

A [{sparse matrix, dense matrix, LinearOperator}] The real-valued N-by-N matrix of the linear system. Alternatively, `A` can be a linear operator which can produce `Ax` and `A^T x` using, e.g., `scipy.sparse.linalg.LinearOperator`.

b [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

Returns

x [{array, matrix}] The converged solution.

info [integer]
Provides convergence information:
0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

Other Parameters

x0 [{array, matrix}] Starting guess for the solution.

tol, atol [float, optional] Tolerances for convergence, `norm(residual) <= max(tol*norm(b), atol)`. The default for `atol` is `'legacy'`, which emulates a different legacy behavior.

> **Warning:** The default value for *atol* will be changed in a future release. For future compatibility, specify *atol* explicitly.

maxiter [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

M1 [{sparse matrix, dense matrix, LinearOperator}] Left preconditioner for A.

M2 [{sparse matrix, dense matrix, LinearOperator}] Right preconditioner for A. Used together with the left preconditioner M1. The matrix M1*A*M2 should have better conditioned than A alone.

callback [function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

See also:

`LinearOperator`

Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import qmr
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = qmr(A, b)
>>> print(exitCode)            # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

scipy.sparse.linalg.gcrotmk

scipy.sparse.linalg.**gcrotmk**(*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=1000*, *M=None*, *callback=None*, *m=20*, *k=None*, *CU=None*, *discard_C=False*, *truncate='oldest'*, *atol=None*)

Solve a matrix equation using flexible GCROT(m,k) algorithm.

Parameters

A [{sparse matrix, dense matrix, LinearOperator}] The real or complex N-by-N matrix of the linear system. Alternatively, `A` can be a linear operator which can produce `Ax` using, e.g., `scipy.sparse.linalg.LinearOperator`.

b [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

x0 [{array, matrix}] Starting guess for the solution.

tol, atol [float, optional] Tolerances for convergence, `norm(residual) <= max(tol*norm(b), atol)`. The default for `atol` is *tol*.

> **Warning:** The default value for *atol* will be changed in a future release. For future compatibility, specify *atol* explicitly.

maxiter [int, optional] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

M [{sparse matrix, dense matrix, LinearOperator}, optional] Preconditioner for A. The preconditioner should approximate the inverse of A. gcrotmk is a 'flexible' algorithm and the preconditioner can vary from iteration to iteration. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

callback [function, optional] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

m [int, optional] Number of inner FGMRES iterations per each outer iteration. Default: 20

k [int, optional] Number of vectors to carry between inner FGMRES iterations. According to [2], good values are around m. Default: m

CU [list of tuples, optional] List of tuples `(c, u)` which contain the columns of the matrices C and U in the GCROT(m,k) algorithm. For details, see [2]. The list given and vectors contained in it are modified in-place. If not given, start from empty matrices. The `c` elements in the tuples can be `None`, in which case the vectors are recomputed via `c = A u` on start and orthogonalized as described in [3].

discard_C [bool, optional] Discard the C-vectors at the end. Useful if recycling Krylov subspaces for different linear systems.

truncate [{'oldest', 'smallest'}, optional] Truncation scheme to use. Drop: oldest vectors, or vectors with smallest singular values using the scheme discussed in [1,2]. See [2] for detailed comparison. Default: 'oldest'

Returns

x [array or matrix] The solution found.

info [int] Provides convergence information:

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations

Iterative methods for least-squares problems:

lsqr(A, b[, damp, atol, btol, conlim, …])	Find the least-squares solution to a large, sparse, linear system of equations.
lsmr(A, b[, damp, atol, btol, conlim, …])	Iterative solver for least-squares problems.

scipy.sparse.linalg.lsqr

scipy.sparse.linalg.**lsqr**(*A*, *b*, *damp=0.0*, *atol=1e-08*, *btol=1e-08*, *conlim=100000000.0*, *iter_lim=None*, *show=False*, *calc_var=False*, *x0=None*)

Find the least-squares solution to a large, sparse, linear system of equations.

The function solves `Ax = b` or `min ||Ax - b||^2` or `min ||Ax - b||^2 + d^2 ||x||^2`.

The matrix A may be square or rectangular (over-determined or under-determined), and may have any rank.

```
1. Unsymmetric equations --    solve  A*x = b

2. Linear least squares  --    solve  A*x = b
                               in the least-squares sense

3. Damped least squares  --    solve  (   A    )*x = ( b )
                                      ( damp*I )     ( 0 )
                               in the least-squares sense
```

Parameters

A [{sparse matrix, ndarray, LinearOperator}] Representation of an m-by-n matrix. Alternatively, `A` can be a linear operator which can produce `Ax` and `A^T x` using, e.g., `scipy.sparse.linalg.LinearOperator`.

b [array_like, shape (m,)] Right-hand side vector `b`.

damp [float] Damping coefficient.

atol, btol [float, optional] Stopping tolerances. If both are 1.0e-9 (say), the final residual norm should be accurate to about 9 digits. (The final x will usually have fewer correct digits, depending on cond(A) and the size of damp.)

conlim [float, optional] Another stopping tolerance. lsqr terminates if an estimate of `cond(A)` exceeds *conlim*. For compatible systems `Ax = b`, *conlim* could be as large as 1.0e+12 (say). For least-squares problems, conlim should be less than 1.0e+8. Maximum precision can be obtained by setting `atol = btol = conlim = zero`, but the number of iterations may then be excessive.

iter_lim [int, optional] Explicit limitation on number of iterations (for safety).

show [bool, optional] Display an iteration log.

calc_var [bool, optional] Whether to estimate diagonals of `(A'A + damp^2*I)^{-1}`.

x0 [array_like, shape (n,), optional] Initial guess of x, if None zeros are used.
New in version 1.0.0.

Returns

x [ndarray of float] The final solution.

istop [int] Gives the reason for termination. 1 means x is an approximate solution to Ax = b. 2 means x approximately solves the least-squares problem.

itn [int] Iteration number upon termination.

r1norm [float] `norm(r)`, where `r = b - Ax`.

r2norm [float] `sqrt( norm(r)^2 + damp^2 * norm(x)^2 )`. Equal to *r1norm* if `damp == 0`.

anorm [float] Estimate of Frobenius norm of `Abar = [[A]; [damp*I]]`.

acond [float] Estimate of `cond(Abar)`.

arnorm [float] Estimate of `norm(A'*r - damp^2*x)`.

xnorm [float] `norm(x)`

var [ndarray of float] If `calc_var` is True, estimates all diagonals of `(A'A)^{-1}` (if `damp == 0`) or more generally `(A'A + damp^2*I)^{-1}`. This is well defined if A has full column rank or `damp > 0`. (Not sure what var means if `rank(A) < n` and `damp = 0`.)

Notes

LSQR uses an iterative method to approximate the solution. The number of iterations required to reach a certain accuracy depends strongly on the scaling of the problem. Poor scaling of the rows or columns of A should therefore be avoided where possible.

For example, in problem 1 the solution is unaltered by row-scaling. If a row of A is very small or large compared to the other rows of A, the corresponding row of (A b) should be scaled up or down.

In problems 1 and 2, the solution x is easily recovered following column-scaling. Unless better information is known, the nonzero columns of A should be scaled so that they all have the same Euclidean norm (e.g., 1.0).

In problem 3, there is no freedom to re-scale if damp is nonzero. However, the value of damp should be assigned only after attention has been paid to the scaling of A.

The parameter damp is intended to help regularize ill-conditioned systems, by preventing the true solution from being very large. Another aid to regularization is provided by the parameter acond, which may be used to terminate iterations before the computed solution becomes very large.

If some initial estimate `x0` is known and if `damp == 0`, one could proceed as follows:

1. Compute a residual vector `r0 = b - A*x0`.
2. Use LSQR to solve the system `A*dx = r0`.

3. Add the correction dx to obtain a final solution `x = x0 + dx`.

This requires that `x0` be available before and after the call to LSQR. To judge the benefits, suppose LSQR takes k1 iterations to solve A*x = b and k2 iterations to solve A*dx = r0. If x0 is "good", norm(r0) will be smaller than norm(b). If the same stopping tolerances atol and btol are used for each system, k1 and k2 will be similar, but the final solution x0 + dx should be more accurate. The only way to reduce the total work is to use a larger stopping tolerance for the second system. If some value btol is suitable for A*x = b, the larger value btol*norm(b)/norm(r0) should be suitable for A*dx = r0.

Preconditioning is another way to reduce the number of iterations. If it is possible to solve a related system `M*x = b` efficiently, where M approximates A in some helpful way (e.g. M - A has low rank or its elements are small relative to those of A), LSQR may converge more rapidly on the system `A*M(inverse)*z = b`, after which x can be recovered by solving M*x = z.

If A is symmetric, LSQR should not be used!

Alternatives are the symmetric conjugate-gradient method (cg) and/or SYMMLQ. SYMMLQ is an implementation of symmetric cg that applies to any symmetric A and will converge more rapidly than LSQR. If A is positive definite, there are other implementations of symmetric cg that require slightly less work per iteration than SYMMLQ (but will take the same number of iterations).

[1], [2], [3]

Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsqr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)
```

The first example has the trivial solution *[0, 0]*

```
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
0
>>> x
array([ 0.,  0.])
```

The stopping code *istop=0* returned indicates that a vector of zeros was found as a solution. The returned solution *x* indeed contains *[0., 0.]*. The next example has a non-trivial solution:

```
>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, r1norm = lsqr(A, b)[:4]
>>> istop
1
>>> x
array([ 1., -1.])
>>> itn
1
>>> r1norm
4.440892098500627e-16
```

As indicated by *istop=1*, `lsqr` found a solution obeying the tolerance limits. The given solution *[1., -1.]* obviously solves the equation. The remaining return values include information about the number of iterations (*itn=1*) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, r1norm = lsqr(A, b)[:4]
>>> istop
2
>>> x
array([ 1.00333333, -0.99666667])
>>> A.dot(x)-b
array([ 0.00333333, -0.00333333,  0.00333333])
>>> r1norm
0.005773502691896255
```

istop indicates that the system is inconsistent and thus *x* is rather an approximate solution to the corresponding least-squares problem. *r1norm* contains the norm of the minimal residual that was found.

scipy.sparse.linalg.lsmr

scipy.sparse.linalg.**lsmr**(*A*, *b*, *damp=0.0*, *atol=1e-06*, *btol=1e-06*, *conlim=100000000.0*, *maxiter=None*, *show=False*, *x0=None*)

Iterative solver for least-squares problems.

lsmr solves the system of linear equations `Ax = b`. If the system is inconsistent, it solves the least-squares problem `min ||b - Ax||_2`. `A` is a rectangular matrix of dimension m-by-n, where all cases are allowed: m = n, m > n, or m < n. `b` is a vector of length m. The matrix A may be dense or sparse (usually sparse).

Parameters

A [{matrix, sparse matrix, ndarray, LinearOperator}] Matrix A in the linear system. Alternatively, `A` can be a linear operator which can produce `Ax` and `A^H x` using, e.g., `scipy.sparse.linalg.LinearOperator`.

b [array_like, shape (m,)] Vector `b` in the linear system.

damp [float] Damping factor for regularized least-squares. `lsmr` solves the regularized least-squares problem:

```
min ||(b) - (  A   )x||
    ||(0)   (damp*I) ||_2
```

where damp is a scalar. If damp is None or 0, the system is solved without regularization.

atol, btol [float, optional] Stopping tolerances. `lsmr` continues iterations until a certain backward error estimate is smaller than some quantity depending on atol and btol. Let `r = b - Ax` be the residual vector for the current approximate solution `x`. If `Ax = b` seems to be consistent, `lsmr` terminates when `norm(r) <= atol * norm(A) * norm(x) + btol * norm(b)`. Otherwise, lsmr terminates when `norm(A^H r) <= atol * norm(A) * norm(r)`. If both tolerances are 1.0e-6 (say), the final `norm(r)` should be accurate to about 6 digits. (The final `x` will usually have fewer correct digits, depending on `cond(A)` and the size of LAMBDA.) If *atol* or *btol* is None, a default value of 1.0e-6 will be used. Ideally, they should be estimates of the relative error in the entries of `A` and `b` respectively. For example, if the entries of `A` have 7 correct digits, set `atol = 1e-7`. This prevents the algorithm from doing unnecessary work beyond the uncertainty of the input data.

conlim [float, optional] `lsmr` terminates if an estimate of `cond(A)` exceeds *conlim*. For compatible systems `Ax = b`, conlim could be as large as 1.0e+12 (say). For least-squares problems, *conlim* should be less than 1.0e+8. If *conlim* is None, the default value is 1e+8. Maximum

precision can be obtained by setting `atol = btol = conlim = 0`, but the number of iterations may then be excessive.

maxiter [int, optional] *lsmr* terminates if the number of iterations reaches *maxiter*. The default is `maxiter = min(m, n)`. For ill-conditioned systems, a larger value of *maxiter* may be needed.

show [bool, optional] Print iterations logs if `show=True`.

x0 [array_like, shape (n,), optional] Initial guess of `x`, if None zeros are used.
New in version 1.0.0.

Returns

x [ndarray of float] Least-square solution returned.

istop [int] istop gives the reason for stopping:

```
istop   = 0 means x=0 is a solution.  If x0 was given, then x=x0 is a
            solution.
        = 1 means x is an approximate solution to A*x = B,
            according to atol and btol.
        = 2 means x approximately solves the least-squares problem
            according to atol.
        = 3 means COND(A) seems to be greater than CONLIM.
        = 4 is the same as 1 with atol = btol = eps (machine
            precision)
        = 5 is the same as 2 with atol = eps.
        = 6 is the same as 3 with CONLIM = 1/eps.
        = 7 means ITN reached maxiter before the other stopping
            conditions were satisfied.
```

itn [int] Number of iterations used.

normr [float] `norm(b-Ax)`

normar [float] `norm(A^H (b - Ax))`

norma [float] `norm(A)`

conda [float] Condition number of A.

normx [float] `norm(x)`

Notes

New in version 0.11.0.

References

[1], [2]

Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsmr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)
```

The first example has the trivial solution *[0, 0]*

```
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:4]
>>> istop
0
>>> x
array([ 0.,  0.])
```

The stopping code *istop=0* returned indicates that a vector of zeros was found as a solution. The returned solution *x* indeed contains *[0., 0.]*. The next example has a non-trivial solution:

```
>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:4]
>>> istop
1
>>> x
array([ 1., -1.])
>>> itn
1
>>> normr
4.440892098500627e-16
```

As indicated by *istop=1*, `lsmr` found a solution obeying the tolerance limits. The given solution *[1., -1.]* obviously solves the equation. The remaining return values include information about the number of iterations (*itn=1*) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:4]
>>> istop
2
>>> x
array([ 1.00333333, -0.99666667])
>>> A.dot(x)-b
array([ 0.00333333, -0.00333333,  0.00333333])
>>> normr
0.005773502691896255
```

istop indicates that the system is inconsistent and thus *x* is rather an approximate solution to the corresponding least-squares problem. *normr* contains the minimal distance that was found.

Matrix factorizations

Eigenvalue problems:

eigs(A[, k, M, sigma, which, v0, ncv, …])	Find k eigenvalues and eigenvectors of the square matrix A.
eigsh(A[, k, M, sigma, which, v0, ncv, …])	Find k eigenvalues and eigenvectors of the real symmetric square matrix or complex Hermitian matrix A.
lobpcg(A, X[, B, M, Y, tol, maxiter, …])	Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

scipy.sparse.linalg.eigs

scipy.sparse.linalg.**eigs**(*A*, *k=6*, *M=None*, *sigma=None*, *which='LM'*, *v0=None*, *ncv=None*, *maxiter=None*, *tol=0*, *return_eigenvectors=True*, *Minv=None*, *OPinv=None*, *OPpart=None*)

Find k eigenvalues and eigenvectors of the square matrix A.

Solves `A * x[i] = w[i] * x[i]`, the standard eigenvalue problem for w[i] eigenvalues with corresponding eigenvectors x[i].

If M is specified, solves `A * x[i] = w[i] * M * x[i]`, the generalized eigenvalue problem for w[i] eigenvalues with corresponding eigenvectors x[i]

Parameters

A [ndarray, sparse matrix or LinearOperator] An array, sparse matrix, or LinearOperator representing the operation `A * x`, where A is a real or complex square matrix.

k [int, optional] The number of eigenvalues and eigenvectors desired. *k* must be smaller than N-1. It is not possible to compute all eigenvectors of a matrix.

M [ndarray, sparse matrix or LinearOperator, optional] An array, sparse matrix, or LinearOperator representing the operation M*x for the generalized eigenvalue problem

A * x = w * M * x.

M must represent a real symmetric matrix if A is real, and must represent a complex Hermitian matrix if A is complex. For best results, the data type of M should be the same as that of A. Additionally:

If *sigma* is None, M is positive definite

If sigma is specified, M is positive semi-definite

If sigma is None, eigs requires an operator to compute the solution of the linear equation `M * x = b`. This is done internally via a (sparse) LU decomposition for an explicit matrix M, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator Minv, which gives `x = Minv * b = M^-1 * b`.

sigma [real or complex, optional] Find eigenvalues near sigma using shift-invert mode. This requires an operator to compute the solution of the linear system `[A - sigma * M] * x = b`, where M is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices A & M, or via an iterative solver if either A or M is a general linear operator. Alternatively, the user can supply the matrix or operator OPinv, which gives `x = OPinv * b = [A - sigma * M]^-1 * b`. For a real matrix A, shift-invert can either be done in imaginary mode or real mode, specified by the parameter OPpart ('r' or 'i'). Note that when sigma is specified, the keyword 'which' (below) refers to the shifted eigenvalues `w'[i]` where:

If A is real and OPpart == 'r' (default),

`w'[i] = 1/2 * [1/(w[i]-sigma) + 1/(w[i]-conj(sigma))].`

If A is real and OPpart == 'i',

`w'[i] = 1/2i * [1/(w[i]-sigma) - 1/(w[i]-conj(sigma))]`.

If A is complex, `w'[i] = 1/(w[i]-sigma)`.

v0 [ndarray, optional] Starting vector for iteration. Default: random

ncv [int, optional] The number of Lanczos vectors generated *ncv* must be greater than *k*; it is recommended that `ncv > 2*k`. Default: `min(n, max(2*k + 1, 20))`

which [str, ['LM' | 'SM' | 'LR' | 'SR' | 'LI' | 'SI'], optional] Which *k* eigenvectors and eigenvalues to find:

'LM' : largest magnitude
'SM' : smallest magnitude
'LR' : largest real part
'SR' : smallest real part
'LI' : largest imaginary part
'SI' : smallest imaginary part

When sigma != None, 'which' refers to the shifted eigenvalues w'[i] (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

maxiter [int, optional] Maximum number of Arnoldi update iterations allowed Default: `n*10`

tol [float, optional] Relative accuracy for eigenvalues (stopping criterion) The default value of 0 implies machine precision.

return_eigenvectors [bool, optional] Return eigenvectors (True) in addition to eigenvalues

Minv [ndarray, sparse matrix or LinearOperator, optional] See notes in M, above.

OPinv [ndarray, sparse matrix or LinearOperator, optional] See notes in sigma, above.

OPpart [{'r' or 'i'}, optional] See notes in sigma, above

Returns

w [ndarray] Array of k eigenvalues.

v [ndarray] An array of *k* eigenvectors. `v[:, i]` is the eigenvector corresponding to the eigenvalue w[i].

Raises

ArpackNoConvergence When the requested convergence is not obtained. The currently converged eigenvalues and eigenvectors can be found as `eigenvalues` and `eigenvectors` attributes of the exception object.

eigsh

eigenvalues and eigenvectors for symmetric matrix A

svds

singular value decomposition for a matrix A

Notes

This function is a wrapper to the ARPACK [1] SNEUPD, DNEUPD, CNEUPD, ZNEUPD, functions which use the Implicitly Restarted Arnoldi Method to find the eigenvalues and eigenvectors [2].

References

[1], [2]

Examples

Find 6 eigenvectors of the identity matrix:

```
>>> from scipy.sparse.linalg import eigs
>>> id = np.eye(13)
>>> vals, vecs = eigs(id, k=6)
>>> vals
array([ 1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j])
>>> vecs.shape
(13, 6)
```

scipy.sparse.linalg.eigsh

scipy.sparse.linalg.**eigsh**(*A*, *k=6*, *M=None*, *sigma=None*, *which='LM'*, *v0=None*, *ncv=None*, *maxiter=None*, *tol=0*, *return_eigenvectors=True*, *Minv=None*, *OPinv=None*, *mode='normal'*)

Find k eigenvalues and eigenvectors of the real symmetric square matrix or complex Hermitian matrix A.

Solves `A * x[i] = w[i] * x[i]`, the standard eigenvalue problem for w[i] eigenvalues with corresponding eigenvectors x[i].

If M is specified, solves `A * x[i] = w[i] * M * x[i]`, the generalized eigenvalue problem for w[i] eigenvalues with corresponding eigenvectors x[i].

Note that there is no specialized routine for the case when A is a complex Hermitian matrix. In this case, `eigsh()` will call `eigs()` and return the real parts of the eigenvalues thus obtained.

Parameters

A [ndarray, sparse matrix or LinearOperator] A square operator representing the operation `A * x`, where `A` is real symmetric or complex Hermitian. For buckling mode (see below) `A` must additionally be positive-definite.

k [int, optional] The number of eigenvalues and eigenvectors desired. *k* must be smaller than N. It is not possible to compute all eigenvectors of a matrix.

Returns

w [array] Array of k eigenvalues.

v [array] An array representing the *k* eigenvectors. The column `v[:, i]` is the eigenvector corresponding to the eigenvalue `w[i]`.

Other Parameters

M [An N x N matrix, array, sparse matrix, or linear operator representing] the operation `M @ x` for the generalized eigenvalue problem

A @ x = w * M @ x.

M must represent a real symmetric matrix if A is real, and must represent a complex Hermitian matrix if A is complex. For best results, the data type of M should be the same as that of A. Additionally:

If sigma is None, M is symmetric positive definite.

If sigma is specified, M is symmetric positive semi-definite.

In buckling mode, M is symmetric indefinite.

If sigma is None, eigsh requires an operator to compute the solution of the linear equation `M @ x = b`. This is done internally via a (sparse) LU decomposition for an explicit matrix M, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator Minv, which gives `x = Minv @ b = M^-1 @ b`.

sigma [real] Find eigenvalues near sigma using shift-invert mode. This requires an operator to compute the solution of the linear system `[A - sigma * M] x = b`, where M is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices A & M, or via an iterative solver if either A or M is a general linear operator. Alternatively, the user can supply the matrix or operator OPinv, which gives `x = OPinv @ b = [A - sigma * M]^-1 @ b`. Note that when sigma is specified, the keyword 'which' refers to the shifted eigenvalues `w'[i]` where:

if mode == 'normal', `w'[i] = 1 / (w[i] - sigma)`.

if mode == 'cayley', `w'[i] = (w[i] + sigma) / (w[i] - sigma)`.

if mode == 'buckling', `w'[i] = w[i] / (w[i] - sigma)`.

(see further discussion in 'mode' below)

v0 [ndarray, optional] Starting vector for iteration. Default: random

ncv [int, optional] The number of Lanczos vectors generated ncv must be greater than k and smaller than n; it is recommended that `ncv > 2*k`. Default: `min(n, max(2*k + 1, 20))`

which [str ['LM' | 'SM' | 'LA' | 'SA' | 'BE']] If A is a complex Hermitian matrix, 'BE' is invalid. Which *k* eigenvectors and eigenvalues to find:

'LM' : Largest (in magnitude) eigenvalues.

'SM' : Smallest (in magnitude) eigenvalues.

'LA' : Largest (algebraic) eigenvalues.

'SA' : Smallest (algebraic) eigenvalues.

'BE' : Half (k/2) from each end of the spectrum.

When k is odd, return one more (k/2+1) from the high end. When sigma != None, 'which' refers to the shifted eigenvalues `w'[i]` (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

maxiter [int, optional] Maximum number of Arnoldi update iterations allowed. Default: `n*10`

tol [float] Relative accuracy for eigenvalues (stopping criterion). The default value of 0 implies machine precision.

Minv [N x N matrix, array, sparse matrix, or LinearOperator] See notes in M, above.

OPinv [N x N matrix, array, sparse matrix, or LinearOperator] See notes in sigma, above.

return_eigenvectors

[bool] Return eigenvectors (True) in addition to eigenvalues. This value determines the order in which eigenvalues are sorted. The sort order is also dependent on the *which* variable.

For which = 'LM' or 'SA':

If *return_eigenvectors* is True, eigenvalues are sorted by algebraic value.

If *return_eigenvectors* is False, eigenvalues are sorted by absolute value.

For which = 'BE' or 'LA':

eigenvalues are always sorted by algebraic value.

For which = 'SM':

If *return_eigenvectors* is True, eigenvalues are sorted by algebraic value.

If *return_eigenvectors* is False, eigenvalues are sorted by decreasing absolute value.

mode [string ['normal' | 'buckling' | 'cayley']] Specify strategy to use for shift-invert mode. This argument applies only for real-valued A and sigma != None. For shift-invert mode, ARPACK internally solves the eigenvalue problem `OP * x'[i] = w'[i] * B * x'[i]` and transforms the resulting Ritz vectors x'[i] and Ritz values w'[i] into the desired eigenvectors and eigenvalues of the problem `A * x[i] = w[i] * M * x[i]`. The modes are as follows:

'normal' : OP = [A - sigma * M]^-1 @ M, B = M, w'[i] = 1 / (w[i] - sigma)

'buckling' : OP = [A - sigma * M]^-1 @ A, B = A, w'[i] = w[i] / (w[i] - sigma)

'cayley' : OP = [A - sigma * M]^-1 @ [A + sigma * M], B = M, w'[i] = (w[i] + sigma) / (w[i] - sigma)

The choice of mode will affect which eigenvalues are selected by the keyword 'which', and can also impact the stability of convergence (see [2] for a discussion).

Raises

ArpackNoConvergence
When the requested convergence is not obtained.
The currently converged eigenvalues and eigenvectors can be found as `eigenvalues` and `eigenvectors` attributes of the exception object.

Examples

```
>>> from scipy.sparse.linalg import eigsh
>>> identity = np.eye(13)
>>> eigenvalues, eigenvectors = eigsh(identity, k=6)
>>> eigenvalues
array([1., 1., 1., 1., 1., 1.])
>>> eigenvectors.shape
(13, 6)
```

scipy.sparse.linalg.lobpcg

scipy.sparse.linalg.**lobpcg**(*A*, *X*, *B=None*, *M=None*, *Y=None*, *tol=None*, *maxiter=None*, *largest=True*, *verbosityLevel=0*, *retLambdaHistory=False*, *retResidualNormsHistory=False*)

Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

LOBPCG is a preconditioned eigensolver for large symmetric positive definite (SPD) generalized eigenproblems.

Parameters

A [{sparse matrix, dense matrix, LinearOperator}] The symmetric linear operator of the problem, usually a sparse matrix. Often called the "stiffness matrix".

X [ndarray, float32 or float64] Initial approximation to the `k` eigenvectors (non-sparse). If *A* has `shape=(n,n)` then *X* should have shape `shape=(n,k)`.

B [{dense matrix, sparse matrix, LinearOperator}, optional] The right hand side operator in a generalized eigenproblem. By default, `B = Identity`. Often called the "mass matrix".

M [{dense matrix, sparse matrix, LinearOperator}, optional] Preconditioner to *A*; by default `M = Identity`. *M* should approximate the inverse of *A*.

Y [ndarray, float32 or float64, optional] n-by-sizeY matrix of constraints (non-sparse), sizeY < n The iterations will be performed in the B-orthogonal complement of the column-space of Y. Y must be full rank.

tol [scalar, optional] Solver tolerance (stopping criterion). The default is `tol=n*sqrt(eps)`.

maxiter [int, optional] Maximum number of iterations. The default is `maxiter = 20`.

largest [bool, optional] When True, solve for the largest eigenvalues, otherwise the smallest.

verbosityLevel [int, optional] Controls solver output. The default is `verbosityLevel=0`.

retLambdaHistory [bool, optional] Whether to return eigenvalue history. Default is False.

retResidualNormsHistory [bool, optional] Whether to return history of residual norms. Default is False.

Returns

w [ndarray] Array of `k` eigenvalues

v [ndarray] An array of `k` eigenvectors. *v* has the same shape as *X*.

lambdas [list of ndarray, optional] The eigenvalue history, if *retLambdaHistory* is True.

rnorms [list of ndarray, optional] The history of residual norms, if *retResidualNormsHistory* is True.

Notes

If both `retLambdaHistory` and `retResidualNormsHistory` are True, the return tuple has the following format `(lambda, V, lambda history, residual norms history)`.

In the following `n` denotes the matrix size and `m` the number of required eigenvalues (smallest or largest).

The LOBPCG code internally solves eigenproblems of the size `3m` on every iteration by calling the "standard" dense eigensolver, so if `m` is not small enough compared to `n`, it does not make sense to call the LOBPCG code, but rather one should use the "standard" eigensolver, e.g. numpy or scipy function in this case. If one calls the LOBPCG algorithm for `5m > n`, it will most likely break internally, so the code tries to call the standard function instead.

It is not that `n` should be large for the LOBPCG to work, but rather the ratio `n / m` should be large. It you call LOBPCG with `m=1` and `n=10`, it works though `n` is small. The method is intended for extremely large `n / m` [4].

The convergence speed depends basically on two factors:

1. How well relatively separated the seeking eigenvalues are from the rest of the eigenvalues. One can try to vary `m` to make this better.

2. How well conditioned the problem is. This can be changed by using proper preconditioning. For example, a rod vibration test problem (under tests directory) is ill-conditioned for large `n`, so convergence will be slow, unless efficient preconditioning is used. For this specific problem, a good simple preconditioner function would be a linear solve for *A*, which is easy to code since A is tridiagonal.

References

[1], [2], [3], [4]

Examples

Solve `A x = lambda x` with constraints and preconditioning.

```
>>> import numpy as np
>>> from scipy.sparse import spdiags, issparse
>>> from scipy.sparse.linalg import lobpcg, LinearOperator
>>> n = 100
>>> vals = np.arange(1, n + 1)
>>> A = spdiags(vals, 0, n, n)
>>> A.toarray()
array([[  1.,   0.,   0., ...,   0.,   0.,   0.],
       [  0.,   2.,   0., ...,   0.,   0.,   0.],
       [  0.,   0.,   3., ...,   0.,   0.,   0.],
       ...,
       [  0.,   0.,   0., ...,  98.,   0.,   0.],
       [  0.,   0.,   0., ...,   0.,  99.,   0.],
       [  0.,   0.,   0., ...,   0.,   0., 100.]])
```

Constraints:

```
>>> Y = np.eye(n, 3)
```

Initial guess for eigenvectors, should have linearly independent columns. Column dimension = number of requested eigenvalues.

```
>>> rng = np.random.default_rng()
>>> X = rng.random((n, 3))
```

Preconditioner in the inverse of A in this example:

```
>>> invA = spdiags([1./vals], 0, n, n)
```

The preconditiner must be defined by a function:

```
>>> def precond( x ):
...     return invA @ x
```

The argument x of the preconditioner function is a matrix inside *lobpcg*, thus the use of matrix-matrix product `@`.

The preconditioner function is passed to lobpcg as a *LinearOperator*:

```
>>> M = LinearOperator(matvec=precond, matmat=precond,
...                    shape=(n, n), dtype=float)
```

Let us now solve the eigenvalue problem for the matrix A:

```
>>> eigenvalues, _ = lobpcg(A, X, Y=Y, M=M, largest=False)
>>> eigenvalues
array([4., 5., 6.])
```

Note that the vectors passed in Y are the eigenvectors of the 3 smallest eigenvalues. The results returned are orthogonal to those.

Singular values problems:

svds(A[, k, ncv, tol, which, v0, maxiter, …])	Compute the largest or smallest k singular values/vectors for a sparse matrix.

scipy.sparse.linalg.svds

scipy.sparse.linalg.**svds**(*A*, *k=6*, *ncv=None*, *tol=0*, *which='LM'*, *v0=None*, *maxiter=None*, *return_singular_vectors=True*, *solver='arpack'*)

Compute the largest or smallest k singular values/vectors for a sparse matrix. The order of the singular values is not guaranteed.

Parameters

A [{sparse matrix, LinearOperator}] Array to compute the SVD on, of shape (M, N)

k [int, optional] Number of singular values and vectors to compute. Must be 1 <= k < min(A.shape).

ncv [int, optional] The number of Lanczos vectors generated ncv must be greater than k+1 and smaller than n; it is recommended that ncv > 2*k Default: `min(n, max(2*k + 1, 20))`

tol [float, optional] Tolerance for singular values. Zero (default) means machine precision.

which [str, [‘LM’ | ‘SM’], optional] Which *k* singular values to find:
- ‘LM’ : largest singular values
- ‘SM’ : smallest singular values

New in version 0.12.0.

v0 [ndarray, optional] Starting vector for iteration, of length min(A.shape). Should be an (approximate) left singular vector if N > M and a right singular vector otherwise. Default: random
New in version 0.12.0.

maxiter [int, optional] Maximum number of iterations.
New in version 0.12.0.

return_singular_vectors
[bool or str, optional]
- True: return singular vectors (True) in addition to singular values.

New in version 0.12.0.
- “u”: only return the u matrix, without computing vh (if N > M).
- “vh”: only return the vh matrix, without computing u (if N <= M).

New in version 0.16.0.

solver [str, optional] Eigenvalue solver to use. Should be ‘arpack’ or ‘lobpcg’. Default: ‘arpack’

Returns

u [ndarray, shape=(M, k)] Unitary matrix having left singular vectors as columns. If *return_singular_vectors* is “vh”, this variable is not computed, and None is returned instead.

s [ndarray, shape=(k,)] The singular values.

vt [ndarray, shape=(k, N)] Unitary matrix having right singular vectors as rows. If *return_singular_vectors* is “u”, this variable is not computed, and None is returned instead.

Notes

This is a naive implementation using ARPACK or LOBPCG as an eigensolver on A.H * A or A * A.H, depending on which one is more efficient.

Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import svds, eigs
>>> A = csc_matrix([[1, 0, 0], [5, 0, 2], [0, -1, 0], [0, 0, 3]],␣
↪dtype=float)
>>> u, s, vt = svds(A, k=2)
>>> s
array([ 2.75193379,  5.6059665 ])
>>> np.sqrt(eigs(A.dot(A.T), k=2)[0]).real
array([ 5.6059665 ,  2.75193379])
```

Complete or incomplete LU factorizations

splu(A[, permc_spec, diag_pivot_thresh, …])	Compute the LU decomposition of a sparse, square matrix.
spilu(A[, drop_tol, fill_factor, drop_rule, …])	Compute an incomplete LU decomposition for a sparse, square matrix.
SuperLU()	LU factorization of a sparse matrix.

scipy.sparse.linalg.splu

scipy.sparse.linalg.**splu**(*A*, *permc_spec=None*, *diag_pivot_thresh=None*, *relax=None*, *panel_size=None*, *options={}*)

Compute the LU decomposition of a sparse, square matrix.

Parameters

A [sparse matrix] Sparse matrix to factorize. Should be in CSR or CSC format.

permc_spec [str, optional] How to permute the columns of the matrix for sparsity preservation. (default: 'COLAMD')

- `NATURAL`: natural ordering.
- `MMD_ATA`: minimum degree ordering on the structure of A^T A.
- `MMD_AT_PLUS_A`: minimum degree ordering on the structure of A^T+A.
- `COLAMD`: approximate minimum degree column ordering

diag_pivot_thresh [float, optional] Threshold used for a diagonal entry to be an acceptable pivot. See SuperLU user's guide for details [1]

relax [int, optional] Expert option for customizing the degree of relaxing supernodes. See SuperLU user's guide for details [1]

panel_size [int, optional] Expert option for customizing the panel size. See SuperLU user's guide for details [1]

options [dict, optional] Dictionary containing additional expert options to SuperLU. See SuperLU user guide [1] (section 2.4 on the 'Options' argument) for more details. For example, you can specify `options=dict(Equil=False, IterRefine='SINGLE'))` to turn equilibration off and perform a single iterative refinement.

Returns

invA [scipy.sparse.linalg.SuperLU] Object, which has a `solve` method.

See also:

spilu

incomplete LU decomposition

Notes

This function uses the SuperLU library.

References

[1]

Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import splu
>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]],␣
↪dtype=float)
>>> B = splu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1. , -3. , -1.5])
>>> A.dot(B.solve(x))
array([ 1.,  2.,  3.])
>>> B.solve(A.dot(x))
array([ 1.,  2.,  3.])
```

scipy.sparse.linalg.spilu

scipy.sparse.linalg.**spilu**(*A*, *drop_tol=None*, *fill_factor=None*, *drop_rule=None*, *permc_spec=None*, *diag_pivot_thresh=None*, *relax=None*, *panel_size=None*, *options=None*)

Compute an incomplete LU decomposition for a sparse, square matrix.

The resulting object is an approximation to the inverse of *A*.

Parameters

A [(N, N) array_like] Sparse matrix to factorize

drop_tol [float, optional] Drop tolerance (0 <= tol <= 1) for an incomplete LU decomposition. (default: 1e-4)

fill_factor [float, optional] Specifies the fill ratio upper bound (>= 1.0) for ILU. (default: 10)

drop_rule [str, optional] Comma-separated string of drop rules to use. Available rules: `basic`, `prows`, `column`, `area`, `secondary`, `dynamic`, `interp`. (Default: `basic,area`) See SuperLU documentation for details.

Remaining other options

Same as for *splu*

Returns

invA_approx

[scipy.sparse.linalg.SuperLU] Object, which has a `solve` method.

See also:

splu

complete LU decomposition

Notes

To improve the better approximation to the inverse, you may need to increase *fill_factor* AND decrease *drop_tol*.

This function uses the SuperLU library.

Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spilu
>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]],␣
↪dtype=float)
>>> B = spilu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1. , -3. , -1.5])
>>> A.dot(B.solve(x))
array([ 1.,  2.,  3.])
>>> B.solve(A.dot(x))
array([ 1.,  2.,  3.])
```

scipy.sparse.linalg.SuperLU

class scipy.sparse.linalg.**SuperLU**

LU factorization of a sparse matrix.

Factorization is represented as:

```
Pr * A * Pc = L * U
```

To construct these *SuperLU* objects, call the *splu* and *spilu* functions.

Notes

New in version 0.14.0.

Examples

The LU decomposition can be used to solve matrix equations. Consider:

```
>>> import numpy as np
>>> from scipy.sparse import csc_matrix, linalg as sla
>>> A = csc_matrix([[1,2,0,4],[1,0,0,1],[1,0,2,1],[2,2,1,0.]])
```

This can be solved for a given right-hand side:

```
>>> lu = sla.splu(A)
>>> b = np.array([1, 2, 3, 4])
>>> x = lu.solve(b)
>>> A.dot(x)
array([ 1.,  2.,  3.,  4.])
```

The `lu` object also contains an explicit representation of the decomposition. The permutations are represented as mappings of indices:

```
>>> lu.perm_r
array([0, 2, 1, 3], dtype=int32)
>>> lu.perm_c
array([2, 0, 1, 3], dtype=int32)
```

The L and U factors are sparse matrices in CSC format:

```
>>> lu.L.A
array([[ 1. ,  0. ,  0. ,  0. ],
       [ 0. ,  1. ,  0. ,  0. ],
       [ 0. ,  0. ,  1. ,  0. ],
       [ 1. ,  0.5,  0.5,  1. ]])
>>> lu.U.A
array([[ 2.,  0.,  1.,  4.],
       [ 0.,  2.,  1.,  1.],
       [ 0.,  0.,  1.,  1.],
       [ 0.,  0.,  0., -5.]])
```

The permutation matrices can be constructed:

```
>>> Pr = csc_matrix((np.ones(4), (lu.perm_r, np.arange(4))))
>>> Pc = csc_matrix((np.ones(4), (np.arange(4), lu.perm_c)))
```

We can reassemble the original matrix:

```
>>> (Pr.T * (lu.L * lu.U) * Pc.T).A
array([[ 1.,  2.,  0.,  4.],
       [ 1.,  0.,  0.,  1.],
       [ 1.,  0.,  2.,  1.],
       [ 2.,  2.,  1.,  0.]])
```

Attributes

shape	Shape of the original matrix as a tuple of ints.
nnz	Number of nonzero elements in the matrix.
perm_c	Permutation Pc represented as an array of indices.
perm_r	Permutation Pr represented as an array of indices.
L	Lower triangular factor with unit diagonal as a *scipy.sparse.csc_matrix*.
U	Upper triangular factor as a *scipy.sparse.csc_matrix*.

Methods

solve(rhs[, trans])	Solves linear system of equations with one or several right-hand sides.

scipy.sparse.linalg.SuperLU.solve

SuperLU.**solve**(*rhs*[, *trans*])

Solves linear system of equations with one or several right-hand sides.

Parameters

rhs [ndarray, shape (n,) or (n, k)] Right hand side(s) of equation

trans [{'N', 'T', 'H'}, optional] Type of system to solve:

```
'N':   A   * x == rhs  (default)
'T':   A^T * x == rhs
'H':   A^H * x == rhs
```

i.e., normal, transposed, and hermitian conjugate.

Returns

x [ndarray, shape `rhs.shape`] Solution vector(s)

Exceptions

ArpackNoConvergence(msg, eigenvalues, ...)	ARPACK iteration did not converge
ArpackError(info[, infodict])	ARPACK error

scipy.sparse.linalg.ArpackNoConvergence

exception scipy.sparse.linalg.**ArpackNoConvergence**(*msg*, *eigenvalues*, *eigenvectors*)

ARPACK iteration did not converge

Attributes

eigenvalues
: [ndarray] Partial result. Converged eigenvalues.

eigenvectors
: [ndarray] Partial result. Converged eigenvectors.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

scipy.sparse.linalg.ArpackError

exception scipy.sparse.linalg.**ArpackError**(*info*, *infodict={'c': {- 9999: 'Could not build an Arnoldi factorization. IPARAM(5) returns the size of the current Arnoldi factorization. with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

3.3.25 Compressed sparse graph routines (scipy.sparse.csgraph)

Fast graph algorithms based on sparse matrix representations.

Contents

connected_components(csgraph[, directed, …])	Analyze the connected components of a sparse graph
laplacian(csgraph[, normed, return_diag, …])	Return the Laplacian matrix of a directed graph.
shortest_path(csgraph[, method, directed, …])	Perform a shortest-path graph search on a positive directed or undirected graph.
dijkstra(csgraph[, directed, indices, …])	Dijkstra algorithm using Fibonacci Heaps
floyd_warshall(csgraph[, directed, …])	Compute the shortest path lengths using the Floyd-Warshall algorithm
bellman_ford(csgraph[, directed, indices, …])	Compute the shortest path lengths using the Bellman-Ford algorithm.
johnson(csgraph[, directed, indices, …])	Compute the shortest path lengths using Johnson's algorithm.
breadth_first_order(csgraph, i_start[, …])	Return a breadth-first ordering starting with specified node.
depth_first_order(csgraph, i_start[, …])	Return a depth-first ordering starting with specified node.
breadth_first_tree(csgraph, i_start[, directed])	Return the tree generated by a breadth-first search
depth_first_tree(csgraph, i_start[, directed])	Return a tree generated by a depth-first search.
minimum_spanning_tree(csgraph[, overwrite])	Return a minimum spanning tree of an undirected graph
reverse_cuthill_mckee(graph[, symmetric_mode])	Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.
maximum_flow(csgraph, source, sink)	Maximize the flow between two vertices in a graph.
maximum_bipartite_matching(graph[, perm_type])	Returns a matching of a bipartite graph whose cardinality is as least that of any given matching of the graph.
min_weight_full_bipartite_matching(…[, …])	Returns the minimum weight full matching of a bipartite graph.
structural_rank(graph)	Compute the structural rank of a graph (matrix) with a given sparsity pattern.
NegativeCycleError([message])	

scipy.sparse.csgraph.connected_components

scipy.sparse.csgraph.**connected_components**(*csgraph*, *directed=True*, *connection='weak'*, *return_labels=True*)

Analyze the connected components of a sparse graph

New in version 0.11.0.

Parameters

csgraph [array_like or sparse matrix] The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.

directed [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

connection
: [str, optional] ['weak'|'strong']. For directed graphs, the type of connection to use. Nodes i and j are strongly connected if a path exists both from i to j and from j to i. A directed graph is weakly connected if replacing all of its directed edges with undirected edges produces a connected (undirected) graph. If directed == False, this keyword is not referenced.

return_labels
: [bool, optional] If True (default), then return the labels for each of the connected components.

Returns

n_components: int
: The number of connected components.

labels: ndarray
: The length-N array of labels of the connected components.

References

[1]

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import connected_components
```

```
>>> graph = [
... [ 0, 1 , 1, 0 , 0 ],
... [ 0, 0 , 1 , 0 ,0 ],
... [ 0, 0, 0, 0, 0],
... [0, 0 , 0, 0, 1],
... [0, 0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
  (0, 1)    1
  (0, 2)    1
  (1, 2)    1
  (3, 4)    1
```

```
>>> n_components, labels = connected_components(csgraph=graph,␣
↪directed=False, return_labels=True)
>>> n_components
2
>>> labels
array([0, 0, 0, 1, 1], dtype=int32)
```

scipy.sparse.csgraph.laplacian

scipy.sparse.csgraph.**laplacian**(*csgraph*, *normed=False*, *return_diag=False*, *use_out_degree=False*)

Return the Laplacian matrix of a directed graph.

Parameters

csgraph [array_like or sparse matrix, 2 dimensions] compressed-sparse graph, with shape (N, N).

normed [bool, optional] If True, then compute symmetric normalized Laplacian.

return_diag [bool, optional] If True, then also return an array related to vertex degrees.

use_out_degree [bool, optional] If True, then use out-degree instead of in-degree. This distinction matters only if the graph is asymmetric. Default: False.

Returns

lap [ndarray or sparse matrix] The N x N laplacian matrix of csgraph. It will be a NumPy array (dense) if the input was dense, or a sparse matrix otherwise.

diag [ndarray, optional] The length-N diagonal of the Laplacian matrix. For the normalized Laplacian, this is the array of square roots of vertex degrees or 1 if the degree is zero.

Notes

The Laplacian matrix of a graph is sometimes referred to as the "Kirchoff matrix" or the "admittance matrix", and is useful in many parts of spectral graph theory. In particular, the eigen-decomposition of the laplacian matrix can give insight into many properties of the graph.

Examples

```
>>> from scipy.sparse import csgraph
>>> G = np.arange(5) * np.arange(5)[:, np.newaxis]
>>> G
array([[ 0,  0,  0,  0,  0],
       [ 0,  1,  2,  3,  4],
       [ 0,  2,  4,  6,  8],
       [ 0,  3,  6,  9, 12],
       [ 0,  4,  8, 12, 16]])
>>> csgraph.laplacian(G, normed=False)
array([[  0,   0,   0,   0,   0],
       [  0,   9,  -2,  -3,  -4],
       [  0,  -2,  16,  -6,  -8],
       [  0,  -3,  -6,  21, -12],
       [  0,  -4,  -8, -12,  24]])
```

scipy.sparse.csgraph.shortest_path

scipy.sparse.csgraph.**shortest_path**(*csgraph*, *method='auto'*, *directed=True*, *return_predecessors=False*, *unweighted=False*, *overwrite=False*, *indices=None*)

Perform a shortest-path graph search on a positive directed or undirected graph.

New in version 0.11.0.

Parameters

csgraph [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.

method [string ['auto'|'FW'|'D'], optional] Algorithm to use for shortest paths. Options are:

'auto' – (default) select the best among 'FW', 'D', 'BF', or 'J'
based on the input data.

'FW' – Floyd-Warshall algorithm. Computational cost is
approximately `O[N^3]`. The input csgraph will be converted to a dense representation.

'D' – Dijkstra's algorithm with Fibonacci heaps. Computational
cost is approximately `O[N(N*k + N*log(N))]`, where `k` is the average number of connected edges per node. The input csgraph will be converted to a csr representation.

'BF' – Bellman-Ford algorithm. This algorithm can be used when
weights are negative. If a negative cycle is encountered, an error will be raised. Computational cost is approximately `O[N(N^2 k)]`, where `k` is the average number of connected edges per node. The input csgraph will be converted to a csr representation.

'J' – Johnson's algorithm. Like the Bellman-Ford algorithm,
Johnson's algorithm is designed for use when the weights are negative. It combines the Bellman-Ford algorithm with Dijkstra's algorithm for faster computation.

directed [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]

return_predecessors
[bool, optional] If True, return the size (N, N) predecesor matrix

unweighted
[bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

overwrite [bool, optional] If True, overwrite csgraph with the result. This applies only if method == 'FW' and csgraph is a dense, c-ordered array with dtype=float64.

indices [array_like or int, optional] If specified, only compute the paths from the points at the given indices. Incompatible with method == 'FW'.

Returns

dist_matrix
[ndarray] The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.

predecessors
[ndarray] Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index

of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

Raises

NegativeCycleError:
if there are negative cycles in the graph

Notes

As currently implemented, Dijkstra's algorithm and Johnson's algorithm do not work for graphs with direction-dependent distances when directed == False. i.e., if csgraph[i,j] and csgraph[j,i] are non-equal edges, method='D' may yield an incorrect result.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import shortest_path
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
  (0, 1)    1
  (0, 2)    2
  (1, 3)    1
  (2, 0)    2
  (2, 3)    3
```

```
>>> dist_matrix, predecessors = shortest_path(csgraph=graph,␣
↪directed=False, indices=0, return_predecessors=True)
>>> dist_matrix
array([ 0.,  1.,  2.,  2.])
>>> predecessors
array([-9999,     0,     0,     1], dtype=int32)
```

scipy.sparse.csgraph.dijkstra

scipy.sparse.csgraph.**dijkstra**(*csgraph*, *directed=True*, *indices=None*, *return_predecessors=False*, *unweighted=False*, *limit=np.inf*, *min_only=False*)

Dijkstra algorithm using Fibonacci Heaps

New in version 0.11.0.

Parameters

csgraph [array, matrix, or sparse matrix, 2 dimensions] The N x N array of non-negative distances representing the input graph.

directed [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j] and from point j to i along paths csgraph[j, i]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j or j to i along either csgraph[i, j] or csgraph[j, i].

indices [array_like or int, optional] if specified, only compute the paths from the points at the given indices.

return_predecessors
[bool, optional] If True, return the size (N, N) predecesor matrix

unweighted
[bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

limit [float, optional] The maximum distance to calculate, must be >= 0. Using a smaller limit will decrease computation time by aborting calculations between pairs that are separated by a distance > limit. For such pairs, the distance will be equal to np.inf (i.e., not connected).
New in version 0.14.0.

min_only [bool, optional] If False (default), for every node in the graph, find the shortest path from every node in indices. If True, for every node in the graph, find the shortest path from any of the nodes in indices (which can be substantially faster).
New in version 1.3.0.

Returns

dist_matrix
[ndarray, shape ([n_indices,]n_nodes,)] The matrix of distances between graph nodes. If min_only=False, dist_matrix has shape (n_indices, n_nodes) and dist_matrix[i, j] gives the shortest distance from point i to point j along the graph. If min_only=True, dist_matrix has shape (n_nodes,) and contains for a given node the shortest path to that node from any of the nodes in indices.

predecessors
[ndarray, shape ([n_indices,]n_nodes,)] If min_only=False, this has shape (n_indices, n_nodes), otherwise it has shape (n_nodes,). Returned only if return_predecessors == True. The matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

sources [ndarray, shape (n_nodes,)] Returned only if min_only=True and return_predecessors=True. Contains the index of the source which had the shortest path to each target. If no path exists within the limit, this will contain -9999. The value at the indices passed will be equal to that index (i.e. the fastest way to reach node i, is to start on node i).

Notes

As currently implemented, Dijkstra's algorithm does not work for graphs with direction-dependent distances when directed == False. i.e., if csgraph[i,j] and csgraph[j,i] are not equal and both are nonzero, setting directed=False will not yield the correct result.

Also, this routine does not work for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms such as Bellman-Ford's algorithm or Johnson's algorithm.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import dijkstra
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
  (0, 1)    1
  (0, 2)    2
  (1, 3)    1
  (2, 3)    3
```

```
>>> dist_matrix, predecessors = dijkstra(csgraph=graph, directed=False,␣
↪indices=0, return_predecessors=True)
>>> dist_matrix
array([ 0.,  1.,  2.,  2.])
>>> predecessors
array([-9999,     0,     0,     1], dtype=int32)
```

scipy.sparse.csgraph.floyd_warshall

scipy.sparse.csgraph.**floyd_warshall**(*csgraph*, *directed=True*, *return_predecessors=False*, *unweighted=False*, *overwrite=False*)

Compute the shortest path lengths using the Floyd-Warshall algorithm

New in version 0.11.0.

Parameters

csgraph [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.

directed [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]

return_predecessors
[bool, optional] If True, return the size (N, N) predecesor matrix

unweighted
[bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

overwrite [bool, optional] If True, overwrite csgraph with the result. This applies only if csgraph is a dense, c-ordered array with dtype=float64.

Returns

dist_matrix
[ndarray] The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.

predecessors
: [ndarray] Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

Raises

NegativeCycleError:
: if there are negative cycles in the graph

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import floyd_warshall
```

```
>>> graph = [
... [0, 1 , 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
  (0, 1)    1
  (0, 2)    2
  (1, 3)    1
  (2, 0)    2
  (2, 3)    3
```

```
>>> dist_matrix, predecessors = floyd_warshall(csgraph=graph,␣
↪directed=False, return_predecessors=True)
>>> dist_matrix
array([[ 0.,  1.,  2.,  2.],
       [ 1.,  0.,  3.,  1.],
       [ 2.,  3.,  0.,  3.],
       [ 2.,  1.,  3.,  0.]])
>>> predecessors
array([[-9999,     0,     0,     1],
       [    1, -9999,     0,     1],
       [    2,     0, -9999,     2],
       [    1,     3,     3, -9999]], dtype=int32)
```

scipy.sparse.csgraph.bellman_ford

scipy.sparse.csgraph.**bellman_ford**(*csgraph*, *directed=True*, *indices=None*, *return_predecessors=False*, *unweighted=False*)

Compute the shortest path lengths using the Bellman-Ford algorithm.

The Bellman-Ford algorithm can robustly deal with graphs with negative weights. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, Dijkstra's algorithm may be faster.

New in version 0.11.0.

Parameters

csgraph [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.

directed [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]

indices [array_like or int, optional] if specified, only compute the paths from the points at the given indices.

return_predecessors
[bool, optional] If True, return the size (N, N) predecesor matrix

unweighted
[bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

Returns

dist_matrix
[ndarray] The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.

predecessors
[ndarray] Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

Raises

NegativeCycleError:
if there are negative cycles in the graph

Notes

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import bellman_ford
```

```
>>> graph = [
... [0, 1 ,2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
  (0, 1)    1
  (0, 2)    2
  (1, 3)    1
  (2, 0)    2
  (2, 3)    3
```

```
>>> dist_matrix, predecessors = bellman_ford(csgraph=graph,␣
↪directed=False, indices=0, return_predecessors=True)
>>> dist_matrix
array([ 0.,  1.,  2.,  2.])
>>> predecessors
array([-9999,     0,     0,     1], dtype=int32)
```

scipy.sparse.csgraph.johnson

scipy.sparse.csgraph.**johnson**(*csgraph*, *directed=True*, *indices=None*, *return_predecessors=False*, *unweighted=False*)

Compute the shortest path lengths using Johnson's algorithm.

Johnson's algorithm combines the Bellman-Ford algorithm and Dijkstra's algorithm to quickly find shortest paths in a way that is robust to the presence of negative cycles. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, dijkstra may be faster.

New in version 0.11.0.

Parameters

csgraph [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.

directed [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]

indices [array_like or int, optional] if specified, only compute the paths from the points at the given indices.

return_predecessors
[bool, optional] If True, return the size (N, N) predecesor matrix

unweighted
[bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

Returns

dist_matrix
: [ndarray] The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.

predecessors
: [ndarray] Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

Raises

NegativeCycleError:
: if there are negative cycles in the graph

Notes

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import johnson
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
  (0, 1)    1
  (0, 2)    2
  (1, 3)    1
  (2, 0)    2
  (2, 3)    3
```

```
>>> dist_matrix, predecessors = johnson(csgraph=graph, directed=False,␣
↪indices=0, return_predecessors=True)
>>> dist_matrix
array([ 0.,  1.,  2.,  2.])
>>> predecessors
array([-9999,     0,     0,     1], dtype=int32)
```

scipy.sparse.csgraph.breadth_first_order

scipy.sparse.csgraph.**breadth_first_order**(*csgraph*, *i_start*, *directed=True*, *return_predecessors=True*)

Return a breadth-first ordering starting with specified node.

Note that a breadth-first order is not unique, but the tree which it generates is unique.

New in version 0.11.0.

Parameters

csgraph [array_like or sparse matrix] The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.

i_start [int] The index of starting node.

directed [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

return_predecessors [bool, optional] If True (default), then return the predecesor array (see below).

Returns

node_array [ndarray, one dimension] The breadth-first list of nodes, starting with specified node. The length of node_array is the number of nodes reachable from the specified node.

predecessors [ndarray, one dimension] Returned only if return_predecessors is True. The length-N list of predecessors of each node in a breadth-first tree. If node i is in the tree, then its parent is given by predecessors[i]. If node i is not in the tree (and for the parent node) then predecessors[i] = -9999.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_order
```

```
>>> graph = [
... [0, 1 , 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
  (0, 1)    1
  (0, 2)    2
  (1, 3)    1
  (2, 0)    2
  (2, 3)    3
```

```
>>> breadth_first_order(graph,0)
(array([0, 1, 2, 3], dtype=int32), array([-9999,     0,     0,     1],␣
↪dtype=int32))
```

scipy.sparse.csgraph.depth_first_order

scipy.sparse.csgraph.**depth_first_order**(*csgraph*, *i_start*, *directed=True*, *return_predecessors=True*)

Return a depth-first ordering starting with specified node.

Note that a depth-first order is not unique. Furthermore, for graphs with cycles, the tree generated by a depth-first search is not unique either.

New in version 0.11.0.

Parameters

csgraph [array_like or sparse matrix] The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.

i_start [int] The index of starting node.

directed [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

return_predecessors [bool, optional] If True (default), then return the predecesor array (see below).

Returns

node_array [ndarray, one dimension] The depth-first list of nodes, starting with specified node. The length of node_array is the number of nodes reachable from the specified node.

predecessors [ndarray, one dimension] Returned only if return_predecessors is True. The length-N list of predecessors of each node in a depth-first tree. If node i is in the tree, then its parent is given by predecessors[i]. If node i is not in the tree (and for the parent node) then predecessors[i] = -9999.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_order
```

```
>>> graph = [
... [0, 1 , 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
  (0, 1)    1
  (0, 2)    2
  (1, 3)    1
  (2, 0)    2
  (2, 3)    3
```

```
>>> depth_first_order(graph,0)
(array([0, 1, 3, 2], dtype=int32), array([-9999,     0,     0,     1],␣
↪dtype=int32))
```

scipy.sparse.csgraph.breadth_first_tree

scipy.sparse.csgraph.**breadth_first_tree**(*csgraph*, *i_start*, *directed=True*)

Return the tree generated by a breadth-first search

Note that a breadth-first tree from a specified node is unique.

New in version 0.11.0.

Parameters

csgraph [array_like or sparse matrix] The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.

i_start [int] The index of starting node.

directed [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

Returns

cstree [csr matrix] The N x N directed compressed-sparse representation of the breadth- first tree drawn from csgraph, starting at the specified node.

Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

```
 input graph           breadth first tree from (0)

     (0)                         (0)
    /   \                       /   \
   3     8                     3     8
  /       \                   /       \
(3)---5---(1)               (3)         (1)
  \       /                               /
   6     2                               2
    \   /                               /
     (2)                             (2)
```

In compressed sparse representation, the solution looks like this:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                 [0, 0, 2, 5],
...                 [0, 0, 0, 6],
...                 [0, 0, 0, 0]])
>>> Tcsr = breadth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 3],
       [0, 0, 2, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. A breadth-first tree from a given node is unique.

scipy.sparse.csgraph.depth_first_tree

scipy.sparse.csgraph.**depth_first_tree**(*csgraph*, *i_start*, *directed=True*)

Return a tree generated by a depth-first search.

Note that a tree generated by a depth-first search is not unique: it depends on the order that the children of each node are searched.

New in version 0.11.0.

Parameters

csgraph [array_like or sparse matrix] The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.

i_start [int] The index of starting node.

directed [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

Returns

cstree [csr matrix] The N x N directed compressed-sparse representation of the depth- first tree drawn from csgraph, starting at the specified node.

Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

```
 input graph            depth first tree from (0)

     (0)                                (0)
    /   \                                \
   3     8                                8
  /       \                                \
(3)---5---(1)                      (3)       (1)
  \       /                          \       /
   6     2                            6     2
    \   /                              \   /
     (2)                                (2)
```

In compressed sparse representation, the solution looks like this:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                 [0, 0, 2, 5],
...                 [0, 0, 0, 6],
...                 [0, 0, 0, 0]])
>>> Tcsr = depth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 0],
       [0, 0, 2, 0],
       [0, 0, 0, 6],
       [0, 0, 0, 0]])
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. Unlike a breadth-first tree, a depth-first tree of a given graph is not unique if the graph contains cycles. If the above solution had begun with the edge connecting nodes 0 and 3, the result would have been different.

scipy.sparse.csgraph.minimum_spanning_tree

scipy.sparse.csgraph.**minimum_spanning_tree**(*csgraph*, *overwrite=False*)

Return a minimum spanning tree of an undirected graph

A minimum spanning tree is a graph consisting of the subset of edges which together connect all connected nodes, while minimizing the total sum of weights on the edges. This is computed using the Kruskal algorithm.

New in version 0.11.0.

Parameters

csgraph [array_like or sparse matrix, 2 dimensions] The N x N matrix representing an undirected graph over N nodes (see notes below).

overwrite [bool, optional] if true, then parts of the input graph will be overwritten for efficiency.

Returns

span_tree [csr matrix] The N x N compressed-sparse representation of the undirected minimum spanning tree over the input (see notes below).

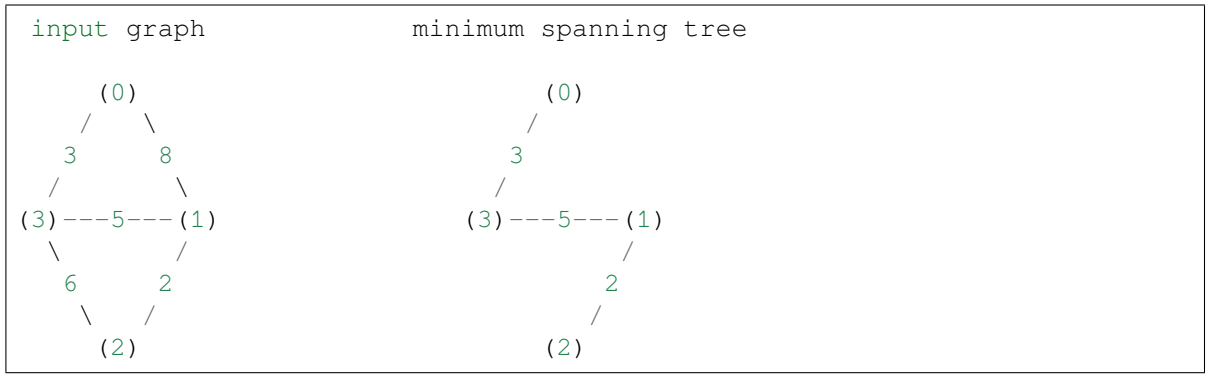
Notes

This routine uses undirected graphs as input and output. That is, if graph[i, j] and graph[j, i] are both zero, then nodes i and j do not have an edge connecting them. If either is nonzero, then the two are connected by the minimum nonzero value of the two.

This routine loses precision when users input a dense matrix. Small elements < 1E-8 of the dense matrix are rounded to zero. All users should input sparse matrices if possible to avoid it.

Examples

The following example shows the computation of a minimum spanning tree over a simple four-component graph:



It is easy to see from inspection that the minimum spanning tree involves removing the edges with weights 8 and 6. In compressed sparse representation, the solution looks like this:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import minimum_spanning_tree
>>> X = csr_matrix([[0, 8, 0, 3],
```

(continues on next page)

(continued from previous page)

```
...                   [0, 0, 2, 5],
...                   [0, 0, 0, 6],
...                   [0, 0, 0, 0]])
>>> Tcsr = minimum_spanning_tree(X)
>>> Tcsr.toarray().astype(int)
array([[0, 0, 0, 3],
       [0, 0, 2, 5],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
```

scipy.sparse.csgraph.reverse_cuthill_mckee

scipy.sparse.csgraph.**reverse_cuthill_mckee**(*graph*, *symmetric_mode=False*)

Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.

It is assumed by default, `symmetric_mode=False`, that the input matrix is not symmetric and works on the matrix `A+A.T`. If you are guaranteed that the matrix is symmetric in structure (values of matrix elements do not matter) then set `symmetric_mode=True`.

Parameters

graph [sparse matrix] Input sparse in CSC or CSR sparse matrix format.

symmetric_mode
[bool, optional] Is input matrix guaranteed to be symmetric.

Returns

perm [ndarray] Array of permuted row and column indices.

Notes

New in version 0.15.0.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import reverse_cuthill_mckee
```

```
>>> graph = [
... [0, 1 , 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
  (0, 1)    1
```

(continues on next page)

(continued from previous page)

```
  (0, 2)    2
  (1, 3)    1
  (2, 0)    2
  (2, 3)    3
```

```
>>> reverse_cuthill_mckee(graph)
array([3, 2, 1, 0], dtype=int32)
```

scipy.sparse.csgraph.maximum_flow

scipy.sparse.csgraph.**maximum_flow**(*csgraph*, *source*, *sink*)

Maximize the flow between two vertices in a graph.

New in version 1.4.0.

Parameters

csgraph [csr_matrix] The square matrix representing a directed graph whose (i, j)'th entry is an integer representing the capacity of the edge between vertices i and j.

source [int] The source vertex from which the flow flows.

sink [int] The sink vertex to which the flow flows.

Returns

res [MaximumFlowResult] A maximum flow represented by a `MaximumFlowResult` which includes the value of the flow in `flow_value`, and the residual graph in `residual`.

Raises

TypeError:
if the input graph is not in CSR format.

ValueError:
if the capacity values are not integers, or the source or sink are out of bounds.

Notes

This solves the maximum flow problem on a given directed weighted graph: A flow associates to every edge a value, also called a flow, less than the capacity of the edge, so that for every vertex (apart from the source and the sink vertices), the total incoming flow is equal to the total outgoing flow. The value of a flow is the sum of the flow of all edges leaving the source vertex, and the maximum flow problem consists of finding a flow whose value is maximal.

By the max-flow min-cut theorem, the maximal value of the flow is also the total weight of the edges in a minimum cut.

To solve the problem, we use the Edmonds–Karp algorithm. [1] This particular implementation strives to exploit sparsity. Its time complexity is $O(VE^2)$ and its space complexity is $O(E)$.

The maximum flow problem is usually defined with real valued capacities, but we require that all capacities are integral to ensure convergence. When dealing with rational capacities, or capacities belonging to $x\mathbb{Q}$ for some fixed $x \in \mathbb{R}$, it is possible to reduce the problem to the integral case by scaling all capacities accordingly.

Solving a maximum-flow problem can be used for example for graph cuts optimization in computer vision [3].

References

[1], [2], [3]

Examples

Perhaps the simplest flow problem is that of a graph of only two vertices with an edge from source (0) to sink (1):

```
(0) --5--> (1)
```

Here, the maximum flow is simply the capacity of the edge:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import maximum_flow
>>> graph = csr_matrix([[0, 5], [0, 0]])
>>> maximum_flow(graph, 0, 1).flow_value
5
```

If, on the other hand, there is a bottleneck between source and sink, that can reduce the maximum flow:

```
(0) --5--> (1) --3--> (2)
```

```
>>> graph = csr_matrix([[0, 5, 0], [0, 0, 3], [0, 0, 0]])
>>> maximum_flow(graph, 0, 2).flow_value
3
```

A less trivial example is given in [2], Chapter 26.1:

```
>>> graph = csr_matrix([[0, 16, 13,  0,  0,  0],
...                     [0, 10,  0, 12,  0,  0],
...                     [0,  4,  0,  0, 14,  0],
...                     [0,  0,  9,  0,  0, 20],
...                     [0,  0,  0,  7,  0,  4],
...                     [0,  0,  0,  0,  0,  0]])
>>> maximum_flow(graph, 0, 5).flow_value
23
```

It is possible to reduce the problem of finding a maximum matching in a bipartite graph to a maximum flow problem: Let $G = ((U, V), E)$ be a bipartite graph. Then, add to the graph a source vertex with edges to every vertex in U and a sink vertex with edges from every vertex in V. Finally, give every edge in the resulting graph a capacity of 1. Then, a maximum flow in the new graph gives a maximum matching in the original graph consisting of the edges in E whose flow is positive.

Assume that the edges are represented by a $|U| \times |V|$ matrix in CSR format whose (i, j)'th entry is 1 if there is an edge from $i \in U$ to $j \in V$ and 0 otherwise; that is, the input is of the form required by *maximum_bipartite_matching*. Then the CSR representation of the graph constructed above contains this matrix as a block. Here's an example:

```
>>> graph = csr_matrix([[0, 1, 0, 1], [1, 0, 1, 0], [0, 1, 1, 0]])
>>> print(graph.toarray())
[[0 1 0 1]
 [1 0 1 0]
 [0 1 1 0]]
```

(continues on next page)

(continued from previous page)

```
>>> i, j = graph.shape
>>> n = graph.nnz
>>> indptr = np.concatenate([[0],
...                          graph.indptr + i,
...                          np.arange(n + i + 1, n + i + j + 1),
...                          [n + i + j]])
>>> indices = np.concatenate([np.arange(1, i + 1),
...                           graph.indices + i + 1,
...                           np.repeat(i + j + 1, j)])
>>> data = np.ones(n + i + j, dtype=int)
>>>
>>> graph_flow = csr_matrix((data, indices, indptr))
>>> print(graph_flow.toarray())
[[0 1 1 1 0 0 0 0 0]
 [0 0 0 0 0 1 0 1 0]
 [0 0 0 0 1 0 1 0 0]
 [0 0 0 0 0 1 1 0 0]
 [0 0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 0 0]]
```

At this point, we can find the maximum flow between the added sink and the added source and the desired matching can be obtained by restricting the residual graph to the block corresponding to the original graph:

```
>>> flow = maximum_flow(graph_flow, 0, i+j+1)
>>> matching = flow.residual[1:i+1, i+1:i+j+1]
>>> print(matching.toarray())
[[0 1 0 0]
 [1 0 0 0]
 [0 0 1 0]]
```

This tells us that the first, second, and third vertex in U are matched with the second, first, and third vertex in V respectively.

While this solves the maximum bipartite matching problem in general, note that algorithms specialized to that problem, such as *maximum_bipartite_matching*, will generally perform better.

This approach can also be used to solve various common generalizations of the maximum bipartite matching problem. If, for instance, some vertices can be matched with more than one other vertex, this may be handled by modifying the capacities of the new graph appropriately.

scipy.sparse.csgraph.maximum_bipartite_matching

scipy.sparse.csgraph.**maximum_bipartite_matching**(*graph*, *perm_type='row'*)

Returns a matching of a bipartite graph whose cardinality is as least that of any given matching of the graph.

Parameters

graph [sparse matrix] Input sparse in CSR format whose rows represent one partition of the graph and whose columns represent the other partition. An edge between two vertices is indicated by the corresponding entry in the matrix existing in its sparse representation.

perm_type [str, {'row', 'column'}] Which partition to return the matching in terms of: If `'row'`, the function produces an array whose length is the number of columns in the input, and whose

j'th element is the row matched to the j'th column. Conversely, if `perm_type` is `'column'`, this returns the columns matched to each row.

Returns

perm [ndarray] A matching of the vertices in one of the two partitions. Unmatched vertices are represented by a `-1` in the result.

Notes

This function implements the Hopcroft–Karp algorithm [1]. Its time complexity is $O(|E|\sqrt{|V|})$, and its space complexity is linear in the number of rows. In practice, this asymmetry between rows and columns means that it can be more efficient to transpose the input if it contains more columns than rows.

By Konig's theorem, the cardinality of the matching is also the number of vertices appearing in a minimum vertex cover of the graph.

Note that if the sparse representation contains explicit zeros, these are still counted as edges.

The implementation was changed in SciPy 1.4.0 to allow matching of general bipartite graphs, where previous versions would assume that a perfect matching existed. As such, code written against 1.4.0 will not necessarily work on older versions.

[1]

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import maximum_bipartite_matching
```

As a simple example, consider a bipartite graph in which the partitions contain 2 and 3 elements respectively. Suppose that one partition contains vertices labelled 0 and 1, and that the other partition contains vertices labelled A, B, and C. Suppose that there are edges connecting 0 and C, 1 and A, and 1 and B. This graph would then be represented by the following sparse matrix:

```
>>> graph = csr_matrix([[0, 0, 1], [1, 1, 0]])
```

Here, the 1s could be anything, as long as they end up being stored as elements in the sparse matrix. We can now calculate maximum matchings as follows:

```
>>> print(maximum_bipartite_matching(graph, perm_type='column'))
[2 0]
>>> print(maximum_bipartite_matching(graph, perm_type='row'))
[ 1 -1  0]
```

The first output tells us that 1 and 2 are matched with C and A respectively, and the second output tells us that A, B, and C are matched with 1, nothing, and 0 respectively.

Note that explicit zeros are still converted to edges. This means that a different way to represent the above graph is by using the CSR structure directly as follows:

```
>>> data = [0, 0, 0]
>>> indices = [2, 0, 1]
>>> indptr = [0, 1, 3]
>>> graph = csr_matrix((data, indices, indptr))
>>> print(maximum_bipartite_matching(graph, perm_type='column'))
[2 0]
>>> print(maximum_bipartite_matching(graph, perm_type='row'))
[ 1 -1  0]
```

When one or both of the partitions are empty, the matching is empty as well:

```
>>> graph = csr_matrix((2, 0))
>>> print(maximum_bipartite_matching(graph, perm_type='column'))
[-1 -1]
>>> print(maximum_bipartite_matching(graph, perm_type='row'))
[]
```

When the input matrix is square, and the graph is known to admit a perfect matching, i.e. a matching with the property that every vertex in the graph belongs to some edge in the matching, then one can view the output as the permutation of rows (or columns) turning the input matrix into one with the property that all diagonal elements are non-empty:

```
>>> a = [[0, 1, 2, 0], [1, 0, 0, 1], [2, 0, 0, 3], [0, 1, 3, 0]]
>>> graph = csr_matrix(a)
>>> perm = maximum_bipartite_matching(graph, perm_type='row')
>>> print(graph[perm].toarray())
[[1 0 0 1]
 [0 1 2 0]
 [0 1 3 0]
 [2 0 0 3]]
```

scipy.sparse.csgraph.min_weight_full_bipartite_matching

scipy.sparse.csgraph.**min_weight_full_bipartite_matching**(*biadjacency_matrix*, *maximize=False*)

Returns the minimum weight full matching of a bipartite graph.

New in version 1.6.0.

Parameters

biadjacency_matrix
: [sparse matrix] Biadjacency matrix of the bipartite graph: A sparse matrix in CSR, CSC, or COO format whose rows represent one partition of the graph and whose columns represent the other partition. An edge between two vertices is indicated by the corresponding entry in the matrix, and the weight of the edge is given by the value of that entry. This should not be confused with the full adjacency matrix of the graph, as we only need the submatrix defining the bipartite structure.

maximize
: [bool (default: False)] Calculates a maximum weight matching if true.

Returns

row_ind, col_ind
: [array] An array of row indices and one of corresponding column indices giving the optimal matching. The total weight of the matching can be computed as `graph[row_ind, col_ind].sum()`. The row indices will be sorted; in the case of a square matrix they will be equal to `numpy.arange(graph.shape[0])`.

Notes

Let $G = ((U, V), E)$ be a weighted bipartite graph with non-zero weights $w : E \to \mathbb{R} \setminus \{0\}$. This function then produces a matching $M \subseteq E$ with cardinality

$$|M| = \min(|U|, |V|),$$

which minimizes the sum of the weights of the edges included in the matching, $\sum_{e \in M} w(e)$, or raises an error if no such matching exists.

When $|U| = |V|$, this is commonly referred to as a perfect matching; here, since we allow $|U|$ and $|V|$ to differ, we follow Karp [1] and refer to the matching as *full*.

This function implements the LAPJVsp algorithm [2], short for "Linear assignment problem, Jonker–Volgenant, sparse".

The problem it solves is equivalent to the rectangular linear assignment problem. [3] As such, this function can be used to solve the same problems as *scipy.optimize.linear_sum_assignment*. That function may perform better when the input is dense, or for certain particular types of inputs, such as those for which the (i, j)'th entry is the distance between two points in Euclidean space.

If no full matching exists, this function raises a `ValueError`. For determining the size of the largest matching in the graph, see *maximum_bipartite_matching*.

We require that weights are non-zero only to avoid issues with the handling of explicit zeros when converting between different sparse representations. Zero weights can be handled by adding a constant to all weights, so that the resulting matrix contains no zeros.

References

[1], [2], [3]

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import min_weight_full_bipartite_matching
```

Let us first consider an example in which all weights are equal:

```
>>> biadjacency_matrix = csr_matrix([[1, 1, 1], [1, 0, 0], [0, 1, 0]])
```

Here, all we get is a perfect matching of the graph:

```
>>> print(min_weight_full_bipartite_matching(biadjacency_matrix)[1])
[2 0 1]
```

That is, the first, second, and third rows are matched with the third, first, and second column respectively. Note that in this example, the 0 in the input matrix does *not* correspond to an edge with weight 0, but rather a pair of vertices not paired by an edge.

Note also that in this case, the output matches the result of applying *maximum_bipartite_matching*:

```
>>> from scipy.sparse.csgraph import maximum_bipartite_matching
>>> biadjacency = csr_matrix([[1, 1, 1], [1, 0, 0], [0, 1, 0]])
>>> print(maximum_bipartite_matching(biadjacency, perm_type='column'))
[2 0 1]
```

When multiple edges are available, the ones with lowest weights are preferred:

```
>>> biadjacency = csr_matrix([[3, 3, 6], [4, 3, 5], [10, 1, 8]])
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(col_ind)
[0 2 1]
```

The total weight in this case is $3 + 5 + 1 = 9$:

```
>>> print(biadjacency[row_ind, col_ind].sum())
9
```

When the matrix is not square, i.e. when the two partitions have different cardinalities, the matching is as large as the smaller of the two partitions:

```
>>> biadjacency = csr_matrix([[0, 1, 1], [0, 2, 3]])
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(row_ind, col_ind)
[0 1] [2 1]
>>> biadjacency = csr_matrix([[0, 1], [3, 1], [1, 4]])
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(row_ind, col_ind)
[0 2] [1 0]
```

When one or both of the partitions are empty, the matching is empty as well:

```
>>> biadjacency = csr_matrix((2, 0))
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(row_ind, col_ind)
[] []
```

In general, we will always reach the same sum of weights as if we had used *scipy.optimize.linear_sum_assignment* but note that for that one, missing edges are represented by a matrix entry of `float('inf')`. Let us generate a random sparse matrix with integer entries between 1 and 10:

```
>>> import numpy as np
>>> from scipy.sparse import random
>>> from scipy.optimize import linear_sum_assignment
>>> sparse = random(10, 10, random_state=42, density=.5, format='coo') *␣
↪10
>>> sparse.data = np.ceil(sparse.data)
>>> dense = sparse.toarray()
>>> dense = np.full(sparse.shape, np.inf)
>>> dense[sparse.row, sparse.col] = sparse.data
>>> sparse = sparse.tocsr()
>>> row_ind, col_ind = linear_sum_assignment(dense)
>>> print(dense[row_ind, col_ind].sum())
28.0
>>> row_ind, col_ind = min_weight_full_bipartite_matching(sparse)
>>> print(sparse[row_ind, col_ind].sum())
28.0
```

scipy.sparse.csgraph.structural_rank

scipy.sparse.csgraph.**structural_rank**(*graph*)

Compute the structural rank of a graph (matrix) with a given sparsity pattern.

The structural rank of a matrix is the number of entries in the maximum transversal of the corresponding bipartite graph, and is an upper bound on the numerical rank of the matrix. A graph has full structural rank if it is possible to permute the elements to make the diagonal zero-free.

New in version 0.19.0.

Parameters

graph [sparse matrix] Input sparse matrix.

Returns

rank [int] The structural rank of the sparse graph.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import structural_rank
```

```
>>> graph = [
... [0, 1, 2, 0],
... [1, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 1, 3, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
  (0, 1)    1
  (0, 2)    2
  (1, 0)    1
  (1, 3)    1
  (2, 0)    2
  (2, 3)    3
  (3, 1)    1
  (3, 2)    3
```

```
>>> structural_rank(graph)
4
```

scipy.sparse.csgraph.NegativeCycleError

exception scipy.sparse.csgraph.**NegativeCycleError**(*message=''*)

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

construct_dist_matrix(graph, predecessors[, …])	Construct distance matrix from a predecessor matrix
csgraph_from_dense(graph[, null_value, …])	Construct a CSR-format sparse graph from a dense matrix.
csgraph_from_masked(graph)	Construct a CSR-format graph from a masked array.
csgraph_masked_from_dense(graph[, …])	Construct a masked array graph representation from a dense matrix.
csgraph_to_dense(csgraph[, null_value])	Convert a sparse graph representation to a dense representation
csgraph_to_masked(csgraph)	Convert a sparse graph representation to a masked array representation
reconstruct_path(csgraph, predecessors[, …])	Construct a tree from a graph and a predecessor list.

scipy.sparse.csgraph.construct_dist_matrix

scipy.sparse.csgraph.**construct_dist_matrix**(*graph*, *predecessors*, *directed=True*, *null_value=np.inf*)

Construct distance matrix from a predecessor matrix

New in version 0.11.0.

Parameters

graph [array_like or sparse] The N x N matrix representation of a directed or undirected graph. If dense, then non-edges are indicated by zeros or infinities.

predecessors [array_like] The N x N matrix of predecessors of each node (see Notes below).

directed [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then operate on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

null_value [bool, optional] value to use for distances between unconnected nodes. Default is np.inf

Returns

dist_matrix [ndarray] The N x N matrix of distances between nodes along the path specified by the predecessor matrix. If no path exists, the distance is zero.

Notes

The predecessor matrix is of the form returned by *shortest_path*. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import construct_dist_matrix
```

```
>>> graph = [
... [0, 1 , 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
  (0, 1)    1
  (0, 2)    2
  (1, 3)    1
  (2, 3)    3
```

```
>>> pred = np.array([[-9999, 0, 0, 2],
... [1, -9999, 0, 1],
... [2, 0, -9999, 2],
... [1, 3, 3, -9999]], dtype=np.int32)
```

```
>>> construct_dist_matrix(graph=graph, predecessors=pred, directed=False)
array([[ 0.,  1.,  2.,  5.],
       [ 1.,  0.,  3.,  1.],
       [ 2.,  3.,  0.,  3.],
       [ 2.,  1.,  3.,  0.]])
```

scipy.sparse.csgraph.csgraph_from_dense

scipy.sparse.csgraph.**csgraph_from_dense**(*graph*, *null_value=0*, *nan_null=True*, *infinity_null=True*)

Construct a CSR-format sparse graph from a dense matrix.

New in version 0.11.0.

Parameters

graph [array_like] Input graph. Shape should be (n_nodes, n_nodes).

null_value [float or None (optional)] Value that denotes non-edges in the graph. Default is zero.

infinity_null [bool] If True (default), then infinite entries (both positive and negative) are treated as null edges.

nan_null [bool] If True (default), then NaN entries are treated as non-edges

Returns

csgraph [csr_matrix] Compressed sparse representation of graph,

Examples

```
>>> from scipy.sparse.csgraph import csgraph_from_dense
```

```
>>> graph = [
... [0, 1 , 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
```

```
>>> csgraph_from_dense(graph)
<4x4 sparse matrix of type '<class 'numpy.float64'>'
    with 4 stored elements in Compressed Sparse Row format>
```

scipy.sparse.csgraph.csgraph_from_masked

scipy.sparse.csgraph.**csgraph_from_masked**(*graph*)

Construct a CSR-format graph from a masked array.

New in version 0.11.0.

Parameters

graph [MaskedArray] Input graph. Shape should be (n_nodes, n_nodes).

Returns

csgraph [csr_matrix] Compressed sparse representation of graph,

Examples

```
>>> import numpy as np
>>> from scipy.sparse.csgraph import csgraph_from_masked
```

```
>>> graph_masked = np.ma.masked_array(data =[
... [0, 1 , 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
...  ],
... mask=[[ True, False, False , True],
... [ True,  True , True, False],
... [ True , True,  True ,False],
... [ True ,True , True , True]],
... fill_value = 0)
```

```
>>> csgraph_from_masked(graph_masked)
<4x4 sparse matrix of type '<class 'numpy.float64'>'
    with 4 stored elements in Compressed Sparse Row format>
```

scipy.sparse.csgraph.csgraph_masked_from_dense

scipy.sparse.csgraph.**csgraph_masked_from_dense**(*graph*, *null_value=0*, *nan_null=True*, *infinity_null=True*, *copy=True*)

Construct a masked array graph representation from a dense matrix.

New in version 0.11.0.

Parameters

graph [array_like] Input graph. Shape should be (n_nodes, n_nodes).
null_value [float or None (optional)] Value that denotes non-edges in the graph. Default is zero.
infinity_null [bool] If True (default), then infinite entries (both positive and negative) are treated as null edges.
nan_null [bool] If True (default), then NaN entries are treated as non-edges

Returns

csgraph [MaskedArray] masked array representation of graph

Examples

```
>>> from scipy.sparse.csgraph import csgraph_masked_from_dense
```

```
>>> graph = [
... [0, 1 , 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
```

```
>>> csgraph_masked_from_dense(graph)
masked_array(
  data=[[--, 1, 2, --],
        [--, --, --, 1],
        [--, --, --, 3],
        [--, --, --, --]],
  mask=[[ True, False, False,  True],
        [ True,  True,  True, False],
        [ True,  True,  True, False],
        [ True,  True,  True,  True]],
  fill_value=0)
```

scipy.sparse.csgraph.csgraph_to_dense

scipy.sparse.csgraph.**csgraph_to_dense**(*csgraph*, *null_value=0*)

Convert a sparse graph representation to a dense representation

New in version 0.11.0.

Parameters

csgraph [csr_matrix, csc_matrix, or lil_matrix] Sparse representation of a graph.
null_value [float, optional] The value used to indicate null edges in the dense representation. Default is 0.

Returns

graph [ndarray] The dense representation of the sparse graph.

Notes

For normal sparse graph representations, calling csgraph_to_dense with null_value=0 produces an equivalent result to using dense format conversions in the main sparse package. When the sparse representations have repeated values, however, the results will differ. The tools in scipy.sparse will add repeating values to obtain a final value. This function will select the minimum among repeating values to obtain a final value. For example, here we'll create a two-node directed sparse graph with multiple edges from node 0 to node 1, of weights 2 and 3. This illustrates the difference in behavior:

```
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([2, 3])
>>> indices = np.array([1, 1])
>>> indptr = np.array([0, 2, 2])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 5],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M)
array([[0., 2.],
       [0., 0.]])
```

The reason for this difference is to allow a compressed sparse graph to represent multiple edges between any two nodes. As most sparse graph algorithms are concerned with the single lowest-cost edge between any two nodes, the default scipy.sparse behavior of summming multiple weights does not make sense in this context.

The other reason for using this routine is to allow for graphs with zero-weight edges. Let's look at the example of a two-node directed graph, connected by an edge of weight zero:

```
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([0.0])
>>> indices = np.array([1])
>>> indptr = np.array([0, 1, 1])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 0],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M, np.inf)
array([[ inf,   0.],
       [ inf,  inf]])
```

In the first case, the zero-weight edge gets lost in the dense representation. In the second case, we can choose a different null value and see the true form of the graph.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import csgraph_to_dense
```

```
>>> graph = csr_matrix( [
... [0, 1 , 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ])
>>> graph
<4x4 sparse matrix of type '<class 'numpy.int64'>'
    with 4 stored elements in Compressed Sparse Row format>
```

```
>>> csgraph_to_dense(graph)
array([[ 0.,  1.,  2.,  0.],
       [ 0.,  0.,  0.,  1.],
       [ 0.,  0.,  0.,  3.],
       [ 0.,  0.,  0.,  0.]])
```

scipy.sparse.csgraph.csgraph_to_masked

scipy.sparse.csgraph.**csgraph_to_masked**(*csgraph*)

Convert a sparse graph representation to a masked array representation

New in version 0.11.0.

Parameters

csgraph [csr_matrix, csc_matrix, or lil_matrix] Sparse representation of a graph.

Returns

graph [MaskedArray] The masked dense representation of the sparse graph.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import csgraph_to_masked
```

```
>>> graph = csr_matrix( [
... [0, 1 , 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ])
>>> graph
<4x4 sparse matrix of type '<class 'numpy.int64'>'
    with 4 stored elements in Compressed Sparse Row format>
```

```
>>> csgraph_to_masked(graph)
masked_array(
```

```

scipy.sparse.csgraph.reconstruct_path

scipy.sparse.csgraph.**reconstruct_path**(*csgraph*, *predecessors*, *directed=True*)

Construct a tree from a graph and a predecessor list.

New in version 0.11.0.

Parameters

csgraph [array_like or sparse matrix] The N x N matrix representing the directed or undirected graph from which the predecessors are drawn.

predecessors [array_like, one dimension] The length-N array of indices of predecessors for the tree. The index of the parent of node i is given by predecessors[i].

directed [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then operate on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

Returns

cstree [csr matrix] The N x N directed compressed-sparse representation of the tree drawn from csgraph which is encoded by the predecessor list.

Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import reconstruct_path
```

```
>>> graph = [
... [0, 1 , 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
  (0, 1)    1
  (0, 2)    2
  (1, 3)    1
  (2, 3)    3
```

```
>>> pred = np.array([-9999, 0, 0, 1], dtype=np.int32)
```

```
>>> cstree = reconstruct_path(csgraph=graph, predecessors=pred,␣
 ↪directed=False)
>>> cstree.todense()
matrix([[ 0.,  1.,  2.,  0.],
        [ 0.,  0.,  0.,  1.],
        [ 0.,  0.,  0.,  0.],
        [ 0.,  0.,  0.,  0.]])
```

Graph Representations

This module uses graphs which are stored in a matrix format. A graph with N nodes can be represented by an (N x N) adjacency matrix G. If there is a connection from node i to node j, then G[i, j] = w, where w is the weight of the connection. For nodes i and j which are not connected, the value depends on the representation:

- for dense array representations, non-edges are represented by G[i, j] = 0, infinity, or NaN.
- for dense masked representations (of type np.ma.MaskedArray), non-edges are represented by masked values. This can be useful when graphs with zero-weight edges are desired.
- for sparse array representations, non-edges are represented by non-entries in the matrix. This sort of sparse representation also allows for edges with zero weights.

As a concrete example, imagine that you would like to represent the following undirected graph:

```
      G

     (0)
    /   \
   1     2
  /       \
(2)       (1)
```

This graph has three nodes, where node 0 and 1 are connected by an edge of weight 2, and nodes 0 and 2 are connected by an edge of weight 1. We can construct the dense, masked, and sparse representations as follows, keeping in mind that an undirected graph is represented by a symmetric matrix:

```
>>> G_dense = np.array([[0, 2, 1],
...                     [2, 0, 0],
...                     [1, 0, 0]])
>>> G_masked = np.ma.masked_values(G_dense, 0)
>>> from scipy.sparse import csr_matrix
>>> G_sparse = csr_matrix(G_dense)
```

This becomes more difficult when zero edges are significant. For example, consider the situation when we slightly modify the above graph:

```
     G2

     (0)
    /   \
   0     2
  /       \
(2)       (1)
```

This is identical to the previous graph, except nodes 0 and 2 are connected by an edge of zero weight. In this case, the dense representation above leads to ambiguities: how can non-edges be represented if zero is a meaningful value? In this case, either a masked or sparse representation must be used to eliminate the ambiguity:

```
>>> G2_data = np.array([[np.inf, 2,      0     ],
...                     [2,      np.inf, np.inf],
...                     [0,      np.inf, np.inf]])
>>> G2_masked = np.ma.masked_invalid(G2_data)
>>> from scipy.sparse.csgraph import csgraph_from_dense
>>> # G2_sparse = csr_matrix(G2_data) would give the wrong result
>>> G2_sparse = csgraph_from_dense(G2_data, null_value=np.inf)
>>> G2_sparse.data
array([ 2.,  0.,  2.,  0.])
```

Here we have used a utility routine from the csgraph submodule in order to convert the dense representation to a sparse representation which can be understood by the algorithms in submodule. By viewing the data array, we can see that the zero values are explicitly encoded in the graph.

Directed vs. undirected

Matrices may represent either directed or undirected graphs. This is specified throughout the csgraph module by a boolean keyword. Graphs are assumed to be directed by default. In a directed graph, traversal from node i to node j can be accomplished over the edge G[i, j], but not the edge G[j, i]. Consider the following dense graph:

```
>>> G_dense = np.array([[0, 1, 0],
...                     [2, 0, 3],
...                     [0, 4, 0]])
```

When `directed=True` we get the graph:

```
  ---1--> ---3-->
(0)     (1)     (2)
  <--2--- <--4---
```

In a non-directed graph, traversal from node i to node j can be accomplished over either G[i, j] or G[j, i]. If both edges are not null, and the two have unequal weights, then the smaller of the two is used.

So for the same graph, when `directed=False` we get the graph:

```
(0)--1--(1)--2--(2)
```

Note that a symmetric matrix will represent an undirected graph, regardless of whether the 'directed' keyword is set to True or False. In this case, using `directed=True` generally leads to more efficient computation.

The routines in this module accept as input either scipy.sparse representations (csr, csc, or lil format), masked representations, or dense representations with non-edges indicated by zeros, infinities, and NaN entries.

3.3.26 Spatial algorithms and data structures (`scipy.spatial`)

Spatial transformations

These are contained in the `scipy.spatial.transform` submodule.

Nearest-neighbor queries

KDTree(data[, leafsize, compact_nodes, …])	kd-tree for quick nearest-neighbor lookup.
cKDTree(data[, leafsize, compact_nodes, …])	kd-tree for quick nearest-neighbor lookup
Rectangle(maxes, mins)	Hyperrectangle class.

scipy.spatial.KDTree

class scipy.spatial.**KDTree**(*data*, *leafsize=10*, *compact_nodes=True*, *copy_data=False*, *balanced_tree=True*, *boxsize=None*)

kd-tree for quick nearest-neighbor lookup.

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

Parameters

data [array_like, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles, and so modifying this data will result in bogus results. The data are also copied if the kd-tree is built with copy_data=True.

leafsize [positive int, optional] The number of points at which the algorithm switches over to brute-force. Default: 10.

compact_nodes
[bool, optional] If True, the kd-tree is built to shrink the hyperrectangles to the actual data range. This usually gives a more compact tree that is robust against degenerated input data and gives faster queries at the expense of longer build time. Default: True.

copy_data [bool, optional] If True the data is always copied to protect the kd-tree against data corruption. Default: False.

balanced_tree
[bool, optional] If True, the median is used to split the hyperrectangles instead of the midpoint. This usually gives a more compact tree and faster queries at the expense of longer build time. Default: True.

boxsize [array_like or scalar, optional] Apply a m-d toroidal topology to the KDTree.. The topology is generated by $x_i + n_i L_i$ where n_i are integers and L_i is the boxsize along i-th dimension. The input data shall be wrapped into $[0, L_i)$. A ValueError is raised if any of the data is outside of this bound.

Notes

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary tree, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the "sliding midpoint" rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the r closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the r approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

Attributes

data	[ndarray, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles. The data are also copied if the kd-tree is built with *copy_data=True*.
leafsize	[positive int] The number of points at which the algorithm switches over to brute-force.
m	[int] The dimension of a single data-point.
n	[int] The number of data points.
maxes	[ndarray, shape (m,)] The maximum value in each dimension of the n data points.
mins	[ndarray, shape (m,)] The minimum value in each dimension of the n data points.
size	[int] The number of nodes in the tree.

Methods

count_neighbors(other, r[, p, weights, …])	Count how many nearby pairs can be formed.
query(x[, k, eps, p, distance_upper_bound, …])	Query the kd-tree for nearest neighbors.
query_ball_point(x, r[, p, eps, workers, …])	Find all points within distance r of point(s) x.
query_ball_tree(other, r[, p, eps])	Find all pairs of points between *self* and *other* whose distance is at most r.
query_pairs(r[, p, eps, output_type])	Find all pairs of points in *self* whose distance is at most r.
sparse_distance_matrix(other, max_distance)	Compute a sparse distance matrix.

scipy.spatial.KDTree.count_neighbors

KDTree.**count_neighbors**(*other*, *r*, *p=2.0*, *weights=None*, *cumulative=True*)

Count how many nearby pairs can be formed.

Count the number of pairs `(x1,x2)` can be formed, with `x1` drawn from `self` and `x2` drawn from `other`, and where `distance(x1, x2, p) <= r`.

Data points on `self` and `other` are optionally weighted by the `weights` argument. (See below)

This is adapted from the "two-point correlation" algorithm described by Gray and Moore [1]. See notes for further discussion.

Parameters

other	[KDTree] The other tree to draw points from, can be the same tree as self.

r [float or one-dimensional array of floats] The radius to produce a count for. Multiple radii are searched with a single tree traversal. If the count is non-cumulative(`cumulative=False`), `r` defines the edges of the bins, and must be non-decreasing.

p [float, optional] 1<=p<=infinity. Which Minkowski p-norm to use. Default 2.0. A finite large p may cause a ValueError if overflow can occur.

weights [tuple, array_like, or None, optional] If None, the pair-counting is unweighted. If given as a tuple, weights[0] is the weights of points in `self`, and weights[1] is the weights of points in `other`; either can be None to indicate the points are unweighted. If given as an array_like, weights is the weights of points in `self` and `other`. For this to make sense, `self` and `other` must be the same tree. If `self` and `other` are two different trees, a `ValueError` is raised. Default: None
New in version 1.6.0.

cumulative [bool, optional] Whether the returned counts are cumulative. When cumulative is set to `False` the algorithm is optimized to work with a large number of bins (>10) specified by `r`. When `cumulative` is set to True, the algorithm is optimized to work with a small number of `r`. Default: True
New in version 1.6.0.

Returns

result [scalar or 1-D array] The number of pairs. For unweighted counts, the result is integer. For weighted counts, the result is float. If cumulative is False, `result[i]` contains the counts with `(-inf if i == 0 else r[i-1]) < R <= r[i]`

Notes

Pair-counting is the basic operation used to calculate the two point correlation functions from a data set composed of position of objects.

Two point correlation function measures the clustering of objects and is widely used in cosmology to quantify the large scale structure in our Universe, but it may be useful for data analysis in other fields where self-similar assembly of objects also occur.

The Landy-Szalay estimator for the two point correlation function of `D` measures the clustering signal in `D`. [2]

For example, given the position of two sets of objects,

- objects `D` (data) contains the clustering signal, and
- objects `R` (random) that contains no signal,

$$\xi(r) = \frac{< D, D > -2f < D, R > +f^2 < R, R >}{f^2 < R, R >},$$

where the brackets represents counting pairs between two data sets in a finite bin around `r` (distance), corresponding to setting *cumulative=False*, and `f = float(len(D)) / float(len(R))` is the ratio between number of objects from data and random.

The algorithm implemented here is loosely based on the dual-tree algorithm described in [1]. We switch between two different pair-cumulation scheme depending on the setting of `cumulative`. The computing time of the method we use when for `cumulative == False` does not scale with the total number of bins. The algorithm for `cumulative == True` scales linearly with the number of bins, though it is slightly faster when only 1 or 2 bins are used. [5].

As an extension to the naive pair-counting, weighted pair-counting counts the product of weights instead of number of pairs. Weighted pair-counting is used to estimate marked correlation functions ([3], section 2.2), or to properly calculate the average of data per distance bin (e.g. [4], section 2.1 on redshift).

Examples

You can count neighbors number between two kd-trees within a distance:

```
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((5, 2))
>>> points2 = rng.random((5, 2))
>>> kd_tree1 = KDTree(points1)
>>> kd_tree2 = KDTree(points2)
>>> kd_tree1.count_neighbors(kd_tree2, 0.2)
1
```

This number is same as the total pair number calculated by *query_ball_tree*:

```
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> sum([len(i) for i in indexes])
1
```

scipy.spatial.KDTree.query

KDTree.**query**(*x*, *k=1*, *eps=0*, *p=2*, *distance_upper_bound=inf*, *workers=1*)

Query the kd-tree for nearest neighbors.

Parameters

x [array_like, last dimension self.m] An array of points to query.

k [int or Sequence[int], optional] Either the number of nearest neighbors to return, or a list of the k-th nearest neighbors to return, starting from 1.

eps [nonnegative float, optional] Return approximate nearest neighbors; the kth returned value is guaranteed to be no further than (1+eps) times the distance to the real kth nearest neighbor.

p [float, 1<=p<=infinity, optional] Which Minkowski p-norm to use. 1 is the sum-of-absolute-values distance ("Manhattan" distance). 2 is the usual Euclidean distance. infinity is the maximum-coordinate-difference distance. A large, finite p may cause a ValueError if overflow can occur.

distance_upper_bound

[nonnegative float, optional] Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.

workers [int, optional] Number of workers to use for parallel processing. If -1 is given all CPU threads are used. Default: 1.
New in version 1.6.0.

Returns

d [float or array of floats] The distances to the nearest neighbors. If `x` has shape `tuple+(self.m,)`, then `d` has shape `tuple+(k,)`. When k == 1, the last dimen-

sion of the output is squeezed. Missing neighbors are indicated with infinite distances. Hits are sorted by distance (nearest first).
Deprecated since version 1.6.0: If `k=None`, then `d` is an object array of shape `tuple`, containing lists of distances. This behavior is deprecated and will be removed in SciPy 1.8.0, use `query_ball_point` instead.

i [integer or array of integers] The index of each neighbor in `self.data`. `i` is the same shape as d. Missing neighbors are indicated with `self.n`.

Examples

```
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = KDTree(np.c_[x.ravel(), y.ravel()])
```

To query the nearest neighbours and return squeezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=1)
>>> print(dd, ii)
[2.         0.14142136] [ 0 13]
```

To query the nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1])
>>> print(dd, ii)
[[2.        ]
 [0.14142136]] [[ 0]
 [13]]
```

To query the second nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[2])
>>> print(dd, ii)
[[2.23606798]
 [0.90553851]] [[ 6]
 [12]]
```

To query the first and second nearest neighbours, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=2)
>>> print(dd, ii)
[[2.         2.23606798]
 [0.14142136 0.90553851]] [[ 0  6]
 [13 12]]
```

or, be more specific

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1, 2])
>>> print(dd, ii)
[[2.         2.23606798]
 [0.14142136 0.90553851]] [[ 0  6]
 [13 12]]
```

scipy.spatial.KDTree.query_ball_point

KDTree.**query_ball_point**(*x*, *r*, *p=2.0*, *eps=0*, *workers=1*, *return_sorted=None*, *return_length=False*)

Find all points within distance r of point(s) x.

Parameters

x [array_like, shape tuple + (self.m,)] The point or points to search for neighbors of.

r [array_like, float] The radius of points to return, must broadcast to the length of x.

p [float, optional] Which Minkowski p-norm to use. Should be in the range [1, inf]. A finite large p may cause a ValueError if overflow can occur.

eps [nonnegative float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than `r / (1 + eps)`, and branches are added in bulk if their furthest points are nearer than `r * (1 + eps)`.

workers [int, optional] Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1.
New in version 1.6.0.

return_sorted
[bool, optional] Sorts returned indicies if True and does not sort them if False. If None, does not sort single point queries, but does sort multi-point queries which was the behavior before this option was added.
New in version 1.6.0.

return_length: bool, optional
Return the number of points inside the radius instead of a list of the indices.
New in version 1.6.0.

Returns

results [list or array of lists] If *x* is a single point, returns a list of the indices of the neighbors of *x*. If *x* is an array of points, returns an object array of shape tuple containing lists of neighbors.

Notes

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a KDTree and using query_ball_tree.

Examples

```
>>> from scipy import spatial
>>> x, y = np.mgrid[0:5, 0:5]
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.KDTree(points)
>>> sorted(tree.query_ball_point([2, 0], 1))
[5, 10, 11, 15]
```

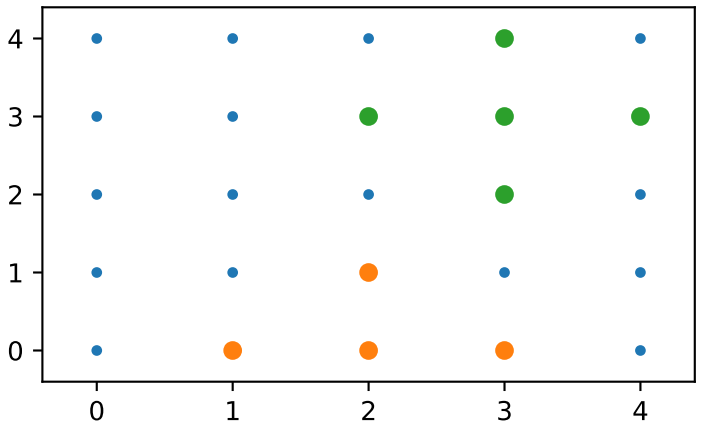
Query multiple points and plot the results:

```
>>> import matplotlib.pyplot as plt
>>> points = np.asarray(points)
>>> plt.plot(points[:,0], points[:,1], '.')
>>> for results in tree.query_ball_point(([2, 0], [3, 3]), 1):
```

(continues on next page)

(continued from previous page)

```
...     nearby_points = points[results]
...     plt.plot(nearby_points[:,0], nearby_points[:,1], 'o')
>>> plt.margins(0.1, 0.1)
>>> plt.show()
```



scipy.spatial.KDTree.query_ball_tree

KDTree.**query_ball_tree**(*other*, *r*, *p=2.0*, *eps=0*)

Find all pairs of points between *self* and *other* whose distance is at most r.

Parameters

other [KDTree instance] The tree containing points to search against.

r [float] The maximum distance, has to be positive.

p [float, optional] Which Minkowski norm to use. *p* has to meet the condition `1 <= p <= infinity`.

eps [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than `r/(1+eps)`, and branches are added in bulk if their furthest points are nearer than `r * (1+eps)`. *eps* has to be non-negative.

Returns

results [list of lists] For each element `self.data[i]` of this tree, `results[i]` is a list of the indices of its neighbors in `other.data`.

Examples

You can search all pairs of points between two kd-trees within a distance:

```
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((15, 2))
>>> points2 = rng.random((15, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points1[:, 0], points1[:, 1], "xk", markersize=14)
>>> plt.plot(points2[:, 0], points2[:, 1], "og", markersize=14)
>>> kd_tree1 = KDTree(points1)
>>> kd_tree2 = KDTree(points2)
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> for i in range(len(indexes)):
...     for j in indexes[i]:
...         plt.plot([points1[i, 0], points2[j, 0]],
...             [points1[i, 1], points2[j, 1]], "-r")
>>> plt.show()
```

scipy.spatial.KDTree.query_pairs

KDTree.**query_pairs**(*r*, *p=2.0*, *eps=0*, *output_type='set'*)

Find all pairs of points in *self* whose distance is at most r.

Parameters

r [positive float] The maximum distance.

p [float, optional] Which Minkowski norm to use. *p* has to meet the condition `1 <= p <= infinity`.

eps [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than `r/(1+eps)`, and branches are added in bulk if their furthest points are nearer than `r * (1+eps)`. *eps* has to be non-negative.

output_type

[string, optional] Choose the output container, 'set' or 'ndarray'. Default: 'set'
New in version 1.6.0.

Returns

results [set or ndarray] Set of pairs `(i,j)`, with `i < j`, for which the corresponding positions are close. If output_type is 'ndarray', an ndarry is returned instead of a set.

Examples

You can search all pairs of points in a kd-tree within a distance:

```
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> rng = np.random.default_rng()
>>> points = rng.random((20, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points[:, 0], points[:, 1], "xk", markersize=14)
>>> kd_tree = KDTree(points)
>>> pairs = kd_tree.query_pairs(r=0.2)
>>> for (i, j) in pairs:
...     plt.plot([points[i, 0], points[j, 0]],
...              [points[i, 1], points[j, 1]], "-r")
>>> plt.show()
```

scipy.spatial.KDTree.sparse_distance_matrix

KDTree.**sparse_distance_matrix**(*other*, *max_distance*, *p=2.0*, *output_type='dok_matrix'*)

Compute a sparse distance matrix.

Computes a distance matrix between two KDTrees, leaving as zero any distance greater than max_distance.

Parameters

other [KDTree]

max_distance
[positive float]

p [float, 1<=p<=infinity] Which Minkowski p-norm to use. A finite large p may cause a ValueError if overflow can occur.

output_type
[string, optional] Which container to use for output data. Options: 'dok_matrix', 'coo_matrix', 'dict', or 'ndarray'. Default: 'dok_matrix'.
New in version 1.6.0.

Returns

result [dok_matrix, coo_matrix, dict or ndarray] Sparse matrix representing the results in "dictionary of keys" format. If a dict is returned the keys are (i,j) tuples of indices. If output_type is 'ndarray' a record array with fields 'i', 'j', and 'v' is returned,

Examples

You can compute a sparse distance matrix between two kd-trees:

```
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((5, 2))
>>> points2 = rng.random((5, 2))
>>> kd_tree1 = KDTree(points1)
>>> kd_tree2 = KDTree(points2)
```

array([[0.        , 0.        , 0.12295571, 0.        , 0.        ],
   [0.        , 0.        , 0.        , 0.        , 0.        ],
   [0.28942611, 0.        , 0.        , 0.2333084 , 0.        ],
   [0.        , 0.        , 0.        , 0.        , 0.        ],
   [0.24617575, 0.29571802, 0.26836782, 0.        , 0.        ]])
```

You can check distances above the *max_distance* are zeros:

```
>>> from scipy.spatial import distance_matrix
>>> distance_matrix(points1, points2)
array([[0.56906522, 0.39923701, 0.12295571, 0.8658745 , 0.79428925],
   [0.37327919, 0.7225693 , 0.87665969, 0.32580855, 0.75679479],
   [0.28942611, 0.30088013, 0.6395831 , 0.2333084 , 0.33630734],
   [0.31994999, 0.72658602, 0.71124834, 0.55396483, 0.90785663],
   [0.24617575, 0.29571802, 0.26836782, 0.57714465, 0.6473269 ]])
```

innernode	
leafnode	
node	

scipy.spatial.cKDTree

class scipy.spatial.**cKDTree**(*data*, *leafsize=16*, *compact_nodes=True*, *copy_data=False*, *balanced_tree=True*, *boxsize=None*)

kd-tree for quick nearest-neighbor lookup

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

Note: *cKDTree* is functionally identical to *KDTree*. Prior to SciPy v1.6.0, *cKDTree* had better performance and slightly different functionality but now the two names exist only for backward-compatibility reasons. If compatibility with SciPy < 1.6 is not a concern, prefer *KDTree*.

Parameters

data [array_like, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles, and so modifying this data will result in bogus results. The data are also copied if the kd-tree is built with copy_data=True.

leafsize [positive int, optional] The number of points at which the algorithm switches over to brute-force. Default: 16.

compact_nodes
[bool, optional] If True, the kd-tree is built to shrink the hyperrectangles to the actual data range. This usually gives a more compact tree that is robust against degenerated input data and gives faster queries at the expense of longer build time. Default: True.

copy_data [bool, optional] If True the data is always copied to protect the kd-tree against data corruption. Default: False.

balanced_tree

[bool, optional] If True, the median is used to split the hyperrectangles instead of the midpoint. This usually gives a more compact tree and faster queries at the expense of longer build time. Default: True.

boxsize [array_like or scalar, optional] Apply a m-d toroidal topology to the KDTree.. The topology is generated by $x_i + n_i L_i$ where n_i are integers and L_i is the boxsize along i-th dimension. The input data shall be wrapped into $[0, L_i)$. A ValueError is raised if any of the data is outside of this bound.

Notes

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary tree, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the "sliding midpoint" rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the r closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the r approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

Attributes

data [ndarray, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles. The data are also copied if the kd-tree is built with *copy_data=True*.

leafsize [positive int] The number of points at which the algorithm switches over to brute-force.

m [int] The dimension of a single data-point.

n [int] The number of data points.

maxes [ndarray, shape (m,)] The maximum value in each dimension of the n data points.

mins [ndarray, shape (m,)] The minimum value in each dimension of the n data points.

tree [object, class cKDTreeNode] This attribute exposes a Python view of the root node in the cKDTree object. A full Python view of the kd-tree is created dynamically on the first access. This attribute allows you to create your own query functions in Python.

size [int] The number of nodes in the tree.

Methods

count_neighbors(self, other, r[, p, …])	Count how many nearby pairs can be formed.
query(self, x[, k, eps, p, …])	Query the kd-tree for nearest neighbors
query_ball_point(self, x, r[, p, eps, …])	Find all points within distance r of point(s) x.
query_ball_tree(self, other, r[, p, eps])	Find all pairs of points between *self* and *other* whose distance is at most r
query_pairs(self, r[, p, eps])	Find all pairs of points in *self* whose distance is at most r.
sparse_distance_matrix(self, other, max_distance)	Compute a sparse distance matrix

scipy.spatial.cKDTree.count_neighbors

cKDTree.**count_neighbors**(*self*, *other*, *r*, *p=2.*, *weights=None*, *cumulative=True*)

Count how many nearby pairs can be formed.

Count the number of pairs `(x1,x2)` can be formed, with `x1` drawn from `self` and `x2` drawn from `other`, and where `distance(x1, x2, p) <= r`.

Data points on `self` and `other` are optionally weighted by the `weights` argument. (See below)

This is adapted from the "two-point correlation" algorithm described by Gray and Moore [1]. See notes for further discussion.

Parameters

other [cKDTree instance] The other tree to draw points from, can be the same tree as self.

r [float or one-dimensional array of floats] The radius to produce a count for. Multiple radii are searched with a single tree traversal. If the count is non-cumulative(`cumulative=False`), `r` defines the edges of the bins, and must be non-decreasing.

p [float, optional] 1<=p<=infinity. Which Minkowski p-norm to use. Default 2.0. A finite large p may cause a ValueError if overflow can occur.

weights [tuple, array_like, or None, optional] If None, the pair-counting is unweighted. If given as a tuple, weights[0] is the weights of points in `self`, and weights[1] is the weights of points in `other`; either can be None to indicate the points are unweighted. If given as an array_like, weights is the weights of points in `self` and `other`. For this to make sense, `self` and `other` must be the same tree. If `self` and `other` are two different trees, a `ValueError` is raised. Default: None

cumulative [bool, optional] Whether the returned counts are cumulative. When cumulative is set to `False` the algorithm is optimized to work with a large number of bins (>10) specified by `r`. When `cumulative` is set to True, the algorithm is optimized to work with a small number of `r`. Default: True

Returns

result [scalar or 1-D array] The number of pairs. For unweighted counts, the result is integer. For weighted counts, the result is float. If cumulative is False, `result[i]` contains the counts with `(-inf if i == 0 else r[i-1]) < R <= r[i]`

Notes

Pair-counting is the basic operation used to calculate the two point correlation functions from a data set composed of position of objects.

Two point correlation function measures the clustering of objects and is widely used in cosmology to quantify the large scale structure in our Universe, but it may be useful for data analysis in other fields where self-similar assembly of objects also occur.

The Landy-Szalay estimator for the two point correlation function of `D` measures the clustering signal in `D`. [2]

For example, given the position of two sets of objects,

- objects `D` (data) contains the clustering signal, and
- objects `R` (random) that contains no signal,

$$\xi(r) = \frac{< D, D > -2f < D, R > +f^2 < R, R >}{f^2 < R, R >},$$

where the brackets represents counting pairs between two data sets in a finite bin around `r` (distance), corresponding to setting *cumulative=False*, and `f = float(len(D)) / float(len(R))` is the ratio between number of objects from data and random.

The algorithm implemented here is loosely based on the dual-tree algorithm described in [1]. We switch between two different pair-cumulation scheme depending on the setting of `cumulative`. The computing time of the method we use when for `cumulative == False` does not scale with the total number of bins. The algorithm for `cumulative == True` scales linearly with the number of bins, though it is slightly faster when only 1 or 2 bins are used. [5].

As an extension to the naive pair-counting, weighted pair-counting counts the product of weights instead of number of pairs. Weighted pair-counting is used to estimate marked correlation functions ([3], section 2.2), or to properly calculate the average of data per distance bin (e.g. [4], section 2.1 on redshift).

Examples

You can count neighbors number between two kd-trees within a distance:

```
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((5, 2))
>>> points2 = rng.random((5, 2))
>>> kd_tree1 = cKDTree(points1)
>>> kd_tree2 = cKDTree(points2)
>>> kd_tree1.count_neighbors(kd_tree2, 0.2)
1
```

This number is same as the total pair number calculated by *query_ball_tree*:

```
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> sum([len(i) for i in indexes])
1
```

scipy.spatial.cKDTree.query

`cKDTree.`**`query`**(*self*, *x*, *k=1*, *eps=0*, *p=2*, *distance_upper_bound=np.inf*, *workers=1*)

Query the kd-tree for nearest neighbors

Parameters

x : [array_like, last dimension self.m] An array of points to query.

k : [list of integer or integer] The list of k-th nearest neighbors to return. If k is an integer it is treated as a list of [1, … k] (range(1, k+1)). Note that the counting starts from 1.

eps : [non-negative float] Return approximate nearest neighbors; the k-th returned value is guaranteed to be no further than (1+eps) times the distance to the real k-th nearest neighbor.

p : [float, 1<=p<=infinity] Which Minkowski p-norm to use. 1 is the sum-of-absolute-values “Manhattan” distance 2 is the usual Euclidean distance infinity is the maximum-coordinate-difference distance A finite large p may cause a ValueError if overflow can occur.

distance_upper_bound
: [nonnegative float] Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.

workers
: [int, optional] Number of workers to use for parallel processing. If -1 is given all CPU threads are used. Default: 1.
Changed in version 1.6.0: The "n_jobs" argument was renamed "workers". The old name "n_jobs" is deprecated and will stop working in SciPy 1.8.0.

Returns

d
: [array of floats] The distances to the nearest neighbors. If `x` has shape `tuple+(self.m,)`, then `d` has shape `tuple+(k,)`. When k == 1, the last dimension of the output is squeezed. Missing neighbors are indicated with infinite distances.

i
: [ndarray of ints] The index of each neighbor in `self.data`. If `x` has shape `tuple+(self.m,)`, then `i` has shape `tuple+(k,)`. When k == 1, the last dimension of the output is squeezed. Missing neighbors are indicated with `self.n`.

Notes

If the KD-Tree is periodic, the position `x` is wrapped into the box.

When the input k is a list, a query for arange(max(k)) is performed, but only columns that store the requested values of k are preserved. This is implemented in a manner that reduces memory usage.

Examples

```
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = cKDTree(np.c_[x.ravel(), y.ravel()])
```

To query the nearest neighbours and return squeezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=1)
>>> print(dd, ii)
[2.         0.14142136] [ 0 13]
```

To query the nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1])
>>> print(dd, ii)
[[2.        ]
 [0.14142136]] [[ 0]
 [13]]
```

To query the second nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[2])
>>> print(dd, ii)
[[2.23606798]
 [0.90553851]] [[ 6]
 [12]]
```

To query the first and second nearest neighbours, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=2)
>>> print(dd, ii)
[[2.         2.23606798]
 [0.14142136 0.90553851]] [[ 0  6]
 [13 12]]
```

or, be more specific

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1, 2])
>>> print(dd, ii)
[[2.         2.23606798]
 [0.14142136 0.90553851]] [[ 0  6]
 [13 12]]
```

scipy.spatial.cKDTree.query_ball_point

cKDTree.**query_ball_point**(*self*, *x*, *r*, *p=2.*, *eps=0*, *workers=1*, *return_sorted=None*, *return_length=False*)

Find all points within distance r of point(s) x.

Parameters

x [array_like, shape tuple + (self.m,)] The point or points to search for neighbors of.

r [array_like, float] The radius of points to return, shall broadcast to the length of x.

p [float, optional] Which Minkowski p-norm to use. Should be in the range [1, inf]. A finite large p may cause a ValueError if overflow can occur.

eps [nonnegative float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than `r / (1 + eps)`, and branches are added in bulk if their furthest points are nearer than `r * (1 + eps)`.

workers [int, optional] Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1.
Changed in version 1.6.0: The “n_jobs” argument was renamed “workers”. The old name “n_jobs” is deprecated and will stop working in SciPy 1.8.0.

return_sorted
[bool, optional] Sorts returned indicies if True and does not sort them if False. If None, does not sort single point queries, but does sort multi-point queries which was the behavior before this option was added.
New in version 1.2.0.

return_length: bool, optional
Return the number of points inside the radius instead of a list of the indices. .. versionadded:: 1.3.0

Returns

results [list or array of lists] If *x* is a single point, returns a list of the indices of the neighbors of *x*. If *x* is an array of points, returns an object array of shape tuple containing lists of neighbors.

Notes

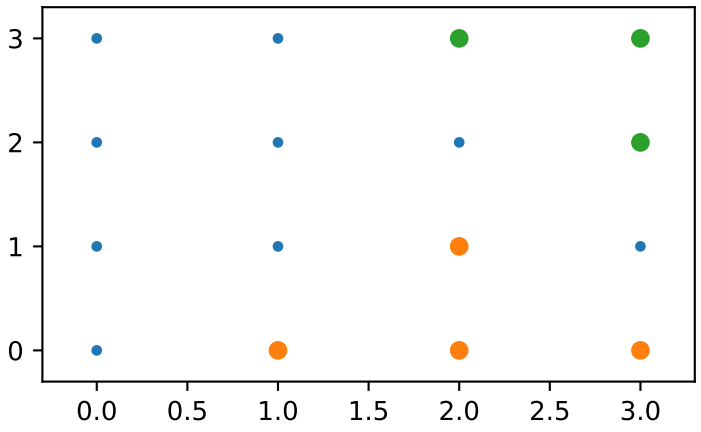
If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a cKDTree and using query_ball_tree.

Examples

```
>>> from scipy import spatial
>>> x, y = np.mgrid[0:4, 0:4]
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.cKDTree(points)
>>> tree.query_ball_point([2, 0], 1)
[4, 8, 9, 12]
```

Query multiple points and plot the results:

```
>>> import matplotlib.pyplot as plt
>>> points = np.asarray(points)
>>> plt.plot(points[:,0], points[:,1], '.')
>>> for results in tree.query_ball_point(([2, 0], [3, 3]), 1):
...     nearby_points = points[results]
...     plt.plot(nearby_points[:,0], nearby_points[:,1], 'o')
>>> plt.margins(0.1, 0.1)
>>> plt.show()
```



scipy.spatial.cKDTree.query_ball_tree

cKDTree.**query_ball_tree**(*self*, *other*, *r*, *p=2.*, *eps=0*)

Find all pairs of points between *self* and *other* whose distance is at most r

Parameters

other [cKDTree instance] The tree containing points to search against.

r [float] The maximum distance, has to be positive.

p [float, optional] Which Minkowski norm to use. *p* has to meet the condition `1 <= p <= infinity`. A finite large p may cause a ValueError if overflow can occur.

eps [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than `r/(1+eps)`, and branches are added in bulk if their furthest points are nearer than `r * (1+eps)`. *eps* has to be non-negative.

Returns

results [list of lists] For each element `self.data[i]` of this tree, `results[i]` is a list of the indices of its neighbors in `other.data`.

Examples

You can search all pairs of points between two kd-trees within a distance:

```
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((15, 2))
>>> points2 = rng.random((15, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points1[:, 0], points1[:, 1], "xk", markersize=14)
>>> plt.plot(points2[:, 0], points2[:, 1], "og", markersize=14)
>>> kd_tree1 = cKDTree(points1)
>>> kd_tree2 = cKDTree(points2)
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> for i in range(len(indexes)):
...     for j in indexes[i]:
...         plt.plot([points1[i, 0], points2[j, 0]],
...             [points1[i, 1], points2[j, 1]], "-r")
>>> plt.show()
```

scipy.spatial.cKDTree.query_pairs

cKDTree.**query_pairs**(*self*, *r*, *p=2.*, *eps=0*)

Find all pairs of points in *self* whose distance is at most r.

Parameters

r [positive float] The maximum distance.

p [float, optional] Which Minkowski norm to use. `p` has to meet the condition `1 <= p <= infinity`. A finite large p may cause a ValueError if overflow can occur.

eps [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than `r/(1+eps)`, and branches are added in bulk if their furthest points are nearer than `r * (1+eps)`. *eps* has to be non-negative.

0.2
0.2
0.4
0.6
0.8
1.0

output_type
[string, optional] Choose the output container, 'set' or 'ndarray'. Default: 'set'

Returns

results [set or ndarray] Set of pairs `(i,j)`, with `i < j`, for which the corresponding positions are close. If output_type is 'ndarray', an ndarry is returned instead of a set.

Examples

You can search all pairs of points in a kd-tree within a distance:

```
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> rng = np.random.default_rng()
>>> points = rng.random((20, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points[:, 0], points[:, 1], "xk", markersize=14)
>>> kd_tree = cKDTree(points)
>>> pairs = kd_tree.query_pairs(r=0.2)
>>> for (i, j) in pairs:
...     plt.plot([points[i, 0], points[j, 0]],
...              [points[i, 1], points[j, 1]], "-r")
>>> plt.show()
```

scipy.spatial.cKDTree.sparse_distance_matrix

cKDTree.**sparse_distance_matrix**(*self*, *other*, *max_distance*, *p=2.*)
Compute a sparse distance matrix

Computes a distance matrix between two cKDTrees, leaving as zero any distance greater than max_distance.

Parameters

other [cKDTree]
max_distance
[positive float]
p [float, 1<=p<=infinity] Which Minkowski p-norm to use. A finite large p may cause a ValueError if overflow can occur.
output_type
[string, optional] Which container to use for output data. Options: 'dok_matrix', 'coo_matrix', 'dict', or 'ndarray'. Default: 'dok_matrix'.

Returns

result [dok_matrix, coo_matrix, dict or ndarray] Sparse matrix representing the results in "dictionary of keys" format. If a dict is returned the keys are (i,j) tuples of indices. If output_type is 'ndarray' a record array with fields 'i', 'j', and 'v' is returned,

Examples

You can compute a sparse distance matrix between two kd-trees:

```
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((5, 2))
>>> points2 = rng.random((5, 2))
>>> kd_tree1 = cKDTree(points1)
>>> kd_tree2 = cKDTree(points2)
>>> sdm = kd_tree1.sparse_distance_matrix(kd_tree2, 0.3)
>>> sdm.toarray()
array([[0.        , 0.        , 0.12295571, 0.        , 0.        ],
   [0.        , 0.        , 0.        , 0.        , 0.        ],
   [0.28942611, 0.        , 0.        , 0.2333084 , 0.        ],
   [0.        , 0.        , 0.        , 0.        , 0.        ],
   [0.24617575, 0.29571802, 0.26836782, 0.        , 0.        ]])
```

You can check distances above the *max_distance* are zeros:

```
>>> from scipy.spatial import distance_matrix
>>> distance_matrix(points1, points2)
array([[0.56906522, 0.39923701, 0.12295571, 0.8658745 , 0.79428925],
   [0.37327919, 0.7225693 , 0.87665969, 0.32580855, 0.75679479],
   [0.28942611, 0.30088013, 0.6395831 , 0.2333084 , 0.33630734],
   [0.31994999, 0.72658602, 0.71124834, 0.55396483, 0.90785663],
   [0.24617575, 0.29571802, 0.26836782, 0.57714465, 0.6473269 ]])
```

scipy.spatial.Rectangle

class scipy.spatial.**Rectangle**(*maxes*, *mins*)

Hyperrectangle class.

Represents a Cartesian product of intervals.

Methods

max_distance_point(x[, p])	Return the maximum distance between input and points in the hyperrectangle.
max_distance_rectangle(other[, p])	Compute the maximum distance between points in the two hyperrectangles.
min_distance_point(x[, p])	Return the minimum distance between input and points in the hyperrectangle.
min_distance_rectangle(other[, p])	Compute the minimum distance between points in the two hyperrectangles.
split(d, split)	Produce two hyperrectangles by splitting.
volume()	Total volume.

scipy.spatial.Rectangle.max_distance_point

Rectangle.**max_distance_point**(*x*, *p=2.0*)

Return the maximum distance between input and points in the hyperrectangle.

Parameters

x	[array_like] Input array.
p	[float, optional] Input.

scipy.spatial.Rectangle.max_distance_rectangle

Rectangle.**max_distance_rectangle**(*other*, *p=2.0*)

Compute the maximum distance between points in the two hyperrectangles.

Parameters

other	[hyperrectangle] Input.
p	[float, optional] Input.

scipy.spatial.Rectangle.min_distance_point

Rectangle.**min_distance_point**(*x*, *p=2.0*)

Return the minimum distance between input and points in the hyperrectangle.

Parameters

x	[array_like] Input.
p	[float, optional] Input.

scipy.spatial.Rectangle.min_distance_rectangle

Rectangle.**min_distance_rectangle**(*other*, *p=2.0*)

Compute the minimum distance between points in the two hyperrectangles.

Parameters

other	[hyperrectangle] Input.
p	[float] Input.

scipy.spatial.Rectangle.split

Rectangle.**split**(*d*, *split*)

Produce two hyperrectangles by splitting.

In general, if you need to compute maximum and minimum distances to the children, it can be done more efficiently by updating the maximum and minimum distances to the parent.

Parameters

d	[int] Axis to split hyperrectangle along.
split	[float] Position along axis *d* to split at.

scipy.spatial.Rectangle.volume

Rectangle.**volume**()
Total volume.

Distance metrics are contained in the *scipy.spatial.distance* submodule.

Delaunay triangulation, convex hulls, and Voronoi diagrams

Delaunay(points[, furthest_site, …])	Delaunay tessellation in N dimensions.
ConvexHull(points[, incremental, qhull_options])	Convex hulls in N dimensions.
Voronoi(points[, furthest_site, …])	Voronoi diagrams in N dimensions.
SphericalVoronoi(points[, radius, center, …])	Voronoi diagrams on the surface of a sphere.
HalfspaceIntersection(halfspaces, interior_point)	Halfspace intersections in N dimensions.

scipy.spatial.Delaunay

class scipy.spatial.**Delaunay**(*points*, *furthest_site=False*, *incremental=False*, *qhull_options=None*)
Delaunay tessellation in N dimensions.

New in version 0.9.

Parameters

points [ndarray of floats, shape (npoints, ndim)] Coordinates of points to triangulate

furthest_site
[bool, optional] Whether to compute a furthest-site Delaunay triangulation. Default: False
New in version 0.12.0.

incremental
[bool, optional] Allow adding new points incrementally. This takes up some additional resources.

qhull_options
[str, optional] Additional options to pass to Qhull. See Qhull manual for details. Option "Qt" is always enabled. Default:"Qbb Qc Qz Qx Q12" for ndim > 4 and "Qbb Qc Qz Q12" otherwise. Incremental mode omits "Qz".
New in version 0.12.0.

Raises

QhullError
Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

ValueError
Raised if an incompatible array is given as input.

Notes

The tessellation is computed using the Qhull library Qhull library.

Note: Unless you pass in the Qhull option "QJ", Qhull does not guarantee that each input point appears as a vertex in the Delaunay triangulation. Omitted points are listed in the *coplanar* attribute.

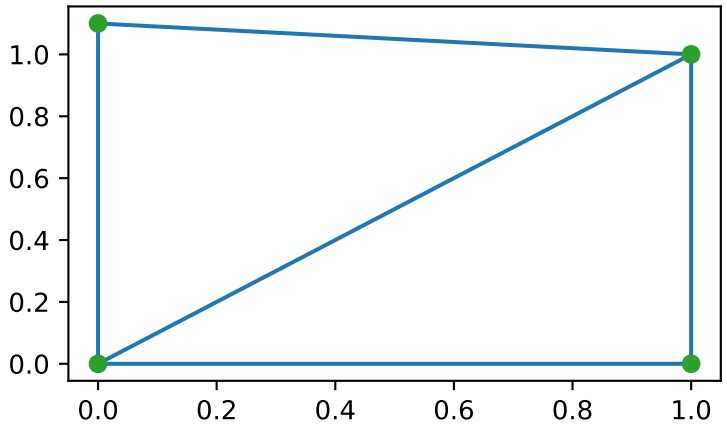
Examples

Triangulation of a set of points:

```
>>> points = np.array([[0, 0], [0, 1.1], [1, 0], [1, 1]])
>>> from scipy.spatial import Delaunay
>>> tri = Delaunay(points)
```

We can plot it:

```
>>> import matplotlib.pyplot as plt
>>> plt.triplot(points[:,0], points[:,1], tri.simplices)
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> plt.show()
```



Point indices and coordinates for the two triangles forming the triangulation:

```
>>> tri.simplices
array([[2, 3, 0],                  # may vary
       [3, 1, 0]], dtype=int32)
```

Note that depending on how rounding errors go, the simplices may be in a different order than above.

```
>>> points[tri.simplices]
array([[[ 1. ,  0. ],             # may vary
```

(continues on next page)

(continued from previous page)

```
        [ 1. ,  1. ],
        [ 0. ,  0. ]],
       [[ 1. ,  1. ],
        [ 0. ,  1.1],
        [ 0. ,  0. ]]])
```

Triangle 0 is the only neighbor of triangle 1, and it's opposite to vertex 1 of triangle 1:

```
>>> tri.neighbors[1]
array([-1,  0, -1], dtype=int32)
>>> points[tri.simplices[1,1]]
array([ 0. ,  1.1])
```

We can find out which triangle points are in:

```
>>> p = np.array([(0.1, 0.2), (1.5, 0.5), (0.5, 1.05)])
>>> tri.find_simplex(p)
array([ 1, -1, 1], dtype=int32)
```

The returned integers in the array are the indices of the simplex the corresponding point is in. If -1 is returned, the point is in no simplex. Be aware that the shortcut in the following example only works corretcly for valid points as invalid points result in -1 which is itself a valid index for the last simplex in the list.

```
>>> p_valids = np.array([(0.1, 0.2), (0.5, 1.05)])
>>> tri.simplices[tri.find_simplex(p_valids)]
array([[3, 1, 0],                   # may vary
       [3, 1, 0]], dtype=int32)
```

We can also compute barycentric coordinates in triangle 1 for these points:

```
>>> b = tri.transform[1,:2].dot(np.transpose(p - tri.transform[1,2]))
>>> np.c_[np.transpose(b), 1 - b.sum(axis=0)]
array([[ 0.1       ,  0.09090909,  0.80909091],
       [ 1.5       , -0.90909091,  0.40909091],
       [ 0.5       ,  0.5       ,  0.        ]])
```

The coordinates for the first point are all positive, meaning it is indeed inside the triangle. The third point is on a vertex, hence its null third coordinate.

Attributes

points [ndarray of double, shape (npoints, ndim)] Coordinates of input points.

simplices [ndarray of ints, shape (nsimplex, ndim+1)] Indices of the points forming the simplices in the triangulation. For 2-D, the points are oriented counterclockwise.

neighbors [ndarray of ints, shape (nsimplex, ndim+1)] Indices of neighbor simplices for each simplex. The kth neighbor is opposite to the kth vertex. For simplices at the boundary, -1 denotes no neighbor.

equations [ndarray of double, shape (nsimplex, ndim+2)] [normal, offset] forming the hyperplane equation of the facet on the paraboloid (see Qhull documentation for more).

paraboloid_scale, paraboloid_shift
[float] Scale and shift for the extra paraboloid dimension (see Qhull documentation for more).

`transform`
[ndarray of double, shape (nsimplex, ndim+1, ndim)] Affine transform from `x` to the barycentric coordinates `c`.

vertex_to_simplex
: [ndarray of int, shape (npoints,)] Lookup array, from a vertex, to some simplex which it is a part of.

convex_hull
: [ndarray of int, shape (nfaces, ndim)] Vertices of facets forming the convex hull of the point set.

coplanar
: [ndarray of int, shape (ncoplanar, 3)] Indices of coplanar points and the corresponding indices of the nearest facet and the nearest vertex. Coplanar points are input points which were *not* included in the triangulation due to numerical precision issues.
If option "Qc" is not specified, this list is not computed.
New in version 0.12.0.

vertices
: Same as *simplices*, but deprecated.

vertex_neighbor_vertices
: [tuple of two ndarrays of int; (indptr, indices)] Neighboring vertices of vertices.

furthest_site
: True if this was a furthest site triangulation and False if not.
New in version 1.4.0.

Methods

add_points(points[, restart])	Process a set of additional new points.
close()	Finish incremental processing.
find_simplex(self, xi[, bruteforce, tol])	Find the simplices containing the given points.
lift_points(self, x)	Lift points to the Qhull paraboloid.
plane_distance(self, xi)	Compute hyperplane distances to the point *xi* from all simplices.

scipy.spatial.Delaunay.add_points

Delaunay.**add_points**(*points*, *restart=False*)

Process a set of additional new points.

Parameters

points
: [ndarray] New points to add. The dimensionality should match that of the initial points.

restart
: [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

Raises

QhullError
: Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

See also:

close

Notes

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after *close* has been called.

scipy.spatial.Delaunay.close

`Delaunay.`**`close`**`()`

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

scipy.spatial.Delaunay.find_simplex

`Delaunay.`**`find_simplex`**(*self*, *xi*, *bruteforce=False*, *tol=None*)

Find the simplices containing the given points.

Parameters

tri	[DelaunayInfo] Delaunay triangulation
xi	[ndarray of double, shape (…, ndim)] Points to locate
bruteforce	[bool, optional] Whether to only perform a brute-force search
tol	[float, optional] Tolerance allowed in the inside-triangle check. Default is `100*eps`.

Returns

i	[ndarray of int, same shape as *xi*] Indices of simplices containing each point. Points outside the triangulation get the value -1.

Notes

This uses an algorithm adapted from Qhull's `qh_findbestfacet`, which makes use of the connection between a convex hull and a Delaunay triangulation. After finding the simplex closest to the point in N+1 dimensions, the algorithm falls back to directed search in N dimensions.

scipy.spatial.Delaunay.lift_points

`Delaunay.`**`lift_points`**(*self*, *x*)

Lift points to the Qhull paraboloid.

scipy.spatial.Delaunay.plane_distance

`Delaunay.`**`plane_distance`**(*self*, *xi*)

Compute hyperplane distances to the point *xi* from all simplices.

scipy.spatial.ConvexHull

class scipy.spatial.**ConvexHull**(*points*, *incremental=False*, *qhull_options=None*)

Convex hulls in N dimensions.

New in version 0.12.0.

Parameters

points [ndarray of floats, shape (npoints, ndim)] Coordinates of points to construct a convex hull from

incremental [bool, optional] Allow adding new points incrementally. This takes up some additional resources.

qhull_options [str, optional] Additional options to pass to Qhull. See Qhull manual for details. (Default: "Qx" for ndim > 4 and "" otherwise) Option "Qt" is always enabled.

Raises

QhullError Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

ValueError Raised if an incompatible array is given as input.

Notes

The convex hull is computed using the Qhull library.

References

[Qhull]

Examples

Convex hull of a random set of points:

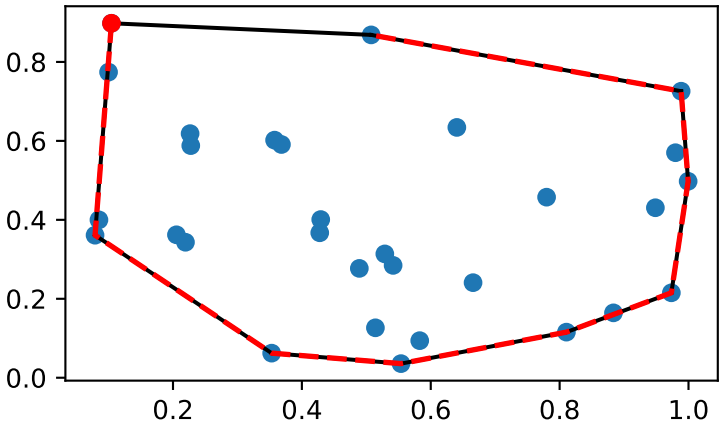
```
>>> from scipy.spatial import ConvexHull, convex_hull_plot_2d
>>> rng = np.random.default_rng()
>>> points = rng.random((30, 2))   # 30 random points in 2-D
>>> hull = ConvexHull(points)
```

Plot it:

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> for simplex in hull.simplices:
...     plt.plot(points[simplex, 0], points[simplex, 1], 'k-')
```

We could also have directly used the vertices of the hull, which for 2-D are guaranteed to be in counterclockwise order:

```
>>> plt.plot(points[hull.vertices,0], points[hull.vertices,1], 'r--',␣
↪lw=2)
>>> plt.plot(points[hull.vertices[0],0], points[hull.vertices[0],1], 'ro')
>>> plt.show()
```



Facets visible from a point:

Create a square and add a point above the square.

```
>>> generators = np.array([[0.2, 0.2],
...                        [0.2, 0.4],
...                        [0.4, 0.4],
...                        [0.4, 0.2],
...                        [0.3, 0.6]])
```

Call ConvexHull with the QG option. QG4 means compute the portions of the hull not including point 4, indicating the facets that are visible from point 4.

```
>>> hull = ConvexHull(points=generators,
...                   qhull_options='QG4')
```

The “good” array indicates which facets are visible from point 4.

```
>>> print(hull.simplices)
    [[1 0]
     [1 2]
     [3 0]
     [3 2]]
>>> print(hull.good)
    [False  True False False]
```

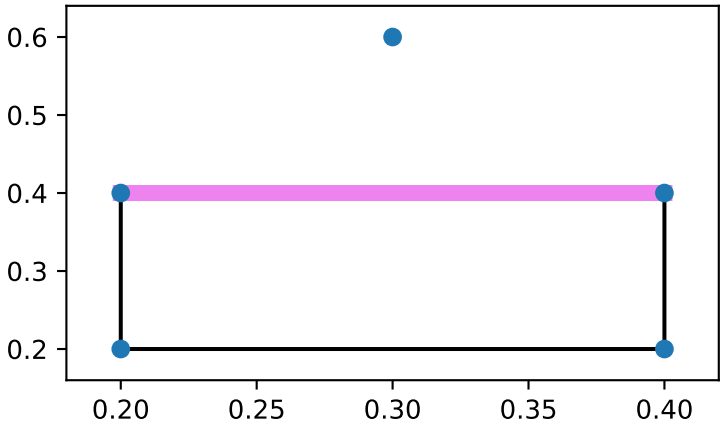
Now plot it, highlighting the visible facets.

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1,1,1)
```

(continues on next page)

(continued from previous page)

```
>>> for visible_facet in hull.simplices[hull.good]:
...     ax.plot(hull.points[visible_facet, 0],
...             hull.points[visible_facet, 1],
...             color='violet',
...             lw=6)
>>> convex_hull_plot_2d(hull, ax=ax)
    <Figure size 640x480 with 1 Axes> # may vary
>>> plt.show()
```



Attributes

points [ndarray of double, shape (npoints, ndim)] Coordinates of input points.

vertices [ndarray of ints, shape (nvertices,)] Indices of points forming the vertices of the convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.

simplices [ndarray of ints, shape (nfacet, ndim)] Indices of points forming the simplical facets of the convex hull.

neighbors [ndarray of ints, shape (nfacet, ndim)] Indices of neighbor facets for each facet. The kth neighbor is opposite to the kth vertex. -1 denotes no neighbor.

equations [ndarray of double, shape (nfacet, ndim+1)] [normal, offset] forming the hyperplane equation of the facet (see Qhull documentation for more).

coplanar [ndarray of int, shape (ncoplanar, 3)] Indices of coplanar points and the corresponding indices of the nearest facets and nearest vertex indices. Coplanar points are input points which were *not* included in the triangulation due to numerical precision issues.
If option "Qc" is not specified, this list is not computed.

good [ndarray of bool or None] A one-dimensional Boolean array indicating which facets are good. Used with options that compute good facets, e.g. QGn and QG-n. Good facets are defined as those that are visible (n) or invisible (-n) from point n, where n is the nth point in 'points'. The 'good' attribute may be used as an index into 'simplices' to return the good (visible) facets: simplices[good]. A facet is visible from the outside of the hull only, and neither coplanarity nor degeneracy count as cases of visibility.
If a "QGn" or "QG-n" option is not specified, None is returned.
New in version 1.3.0.

area [float] Surface area of the convex hull when input dimension > 2. When input `points` are 2-dimensional, this is the perimeter of the convex hull.
New in version 0.17.0.

volume [float] Volume of the convex hull when input dimension > 2. When input `points` are 2-dimensional, this is the area of the convex hull.
New in version 0.17.0.

Methods

add_points(points[, restart])	Process a set of additional new points.
close()	Finish incremental processing.

scipy.spatial.ConvexHull.add_points

ConvexHull.**add_points**(*points*, *restart=False*)

Process a set of additional new points.

Parameters

points [ndarray] New points to add. The dimensionality should match that of the initial points.

restart [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

Raises

QhullError

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

See also:

close

Notes

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after *close* has been called.

scipy.spatial.ConvexHull.close

ConvexHull.**close**()

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

scipy.spatial.Voronoi

class scipy.spatial.**Voronoi**(*points*, *furthest_site=False*, *incremental=False*, *qhull_options=None*)

Voronoi diagrams in N dimensions.

New in version 0.12.0.

Parameters

points [ndarray of floats, shape (npoints, ndim)] Coordinates of points to construct a Voronoi diagram from

furthest_site
[bool, optional] Whether to compute a furthest-site Voronoi diagram. Default: False

incremental
[bool, optional] Allow adding new points incrementally. This takes up some additional resources.

qhull_options
[str, optional] Additional options to pass to Qhull. See Qhull manual for details. (Default: "Qbb Qc Qz Qx" for ndim > 4 and "Qbb Qc Qz" otherwise. Incremental mode omits "Qz".)

Raises

QhullError
Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

ValueError
Raised if an incompatible array is given as input.

Notes

The Voronoi diagram is computed using the Qhull library.

Examples

Voronoi diagram for a set of point:

```
>>> points = np.array([[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2],
...                    [2, 0], [2, 1], [2, 2]])
>>> from scipy.spatial import Voronoi, voronoi_plot_2d
>>> vor = Voronoi(points)
```

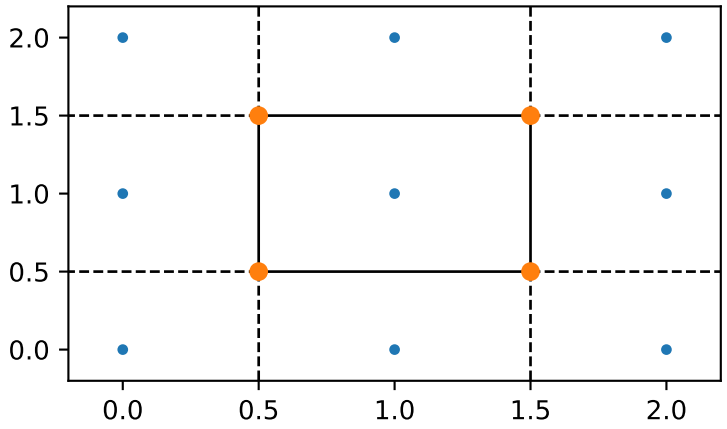
Plot it:

```
>>> import matplotlib.pyplot as plt
>>> fig = voronoi_plot_2d(vor)
>>> plt.show()
```

The Voronoi vertices:

```
>>> vor.vertices
array([[0.5, 0.5],
       [0.5, 1.5],
       [1.5, 0.5],
       [1.5, 1.5]])
```

There is a single finite Voronoi region, and four finite Voronoi ridges:



```
>>> vor.regions
[[], [-1, 0], [-1, 1], [1, -1, 0], [3, -1, 2], [-1, 3], [-1, 2], [0, 1, 3,
 ↪ 2], [2, -1, 0], [3, -1, 1]]
>>> vor.ridge_vertices
[[-1, 0], [-1, 0], [-1, 1], [-1, 1], [0, 1], [-1, 3], [-1, 2], [2, 3], [-
↪1, 3], [-1, 2], [1, 3], [0, 2]]
```

The ridges are perpendicular between lines drawn between the following input points:

```
>>> vor.ridge_points
array([[0, 3],
       [0, 1],
       [2, 5],
       [2, 1],
       [1, 4],
       [7, 8],
       [7, 6],
       [7, 4],
       [8, 5],
       [6, 3],
       [4, 5],
       [4, 3]], dtype=int32)
```

Attributes

points [ndarray of double, shape (npoints, ndim)] Coordinates of input points.
vertices [ndarray of double, shape (nvertices, ndim)] Coordinates of the Voronoi vertices.
ridge_points
[ndarray of ints, shape `(nridges, 2)`] Indices of the points between which each Voronoi ridge lies.
ridge_vertices
[list of list of ints, shape `(nridges, *)`] Indices of the Voronoi vertices forming each Voronoi ridge.

regions [list of list of ints, shape `(nregions, *)`] Indices of the Voronoi vertices forming each Voronoi region. -1 indicates vertex outside the Voronoi diagram.

point_region
[list of ints, shape (npoints)] Index of the Voronoi region for each input point. If qhull option "Qc" was not specified, the list will contain -1 for points that are not associated with a Voronoi region.

furthest_site
True if this was a furthest site triangulation and False if not.
New in version 1.4.0.

Methods

add_points(points[, restart])	Process a set of additional new points.
close()	Finish incremental processing.

scipy.spatial.Voronoi.add_points

Voronoi.**add_points**(*points*, *restart=False*)

Process a set of additional new points.

Parameters

points [ndarray] New points to add. The dimensionality should match that of the initial points.

restart [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

Raises

QhullError
Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

See also:

close

Notes

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after *close* has been called.

scipy.spatial.Voronoi.close

Voronoi.**close**()

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

scipy.spatial.SphericalVoronoi

class scipy.spatial.**SphericalVoronoi**(*points*, *radius=1*, *center=None*, *threshold=1e-06*)

Voronoi diagrams on the surface of a sphere.

New in version 0.18.0.

Parameters

points [ndarray of floats, shape (npoints, ndim)] Coordinates of points from which to construct a spherical Voronoi diagram.

radius [float, optional] Radius of the sphere (Default: 1)

center [ndarray of floats, shape (ndim,)] Center of sphere (Default: origin)

threshold [float] Threshold for detecting duplicate points and mismatches between points and sphere parameters. (Default: 1e-06)

Raises

ValueError
If there are duplicates in *points*. If the provided *radius* is not consistent with *points*.

See also:

`Voronoi`

Conventional Voronoi diagrams in N dimensions.

Notes

The spherical Voronoi diagram algorithm proceeds as follows. The Convex Hull of the input points (generators) is calculated, and is equivalent to their Delaunay triangulation on the surface of the sphere [Caroli]. The Convex Hull neighbour information is then used to order the Voronoi region vertices around each generator. The latter approach is substantially less sensitive to floating point issues than angle-based methods of Voronoi region vertex sorting.

Empirical assessment of spherical Voronoi algorithm performance suggests quadratic time complexity (loglinear is optimal, but algorithms are more challenging to implement).

References

[Caroli], [VanOosterom]

Examples

Do some imports and take some points on a cube:

```
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import SphericalVoronoi, geometric_slerp
>>> from mpl_toolkits.mplot3d import proj3d
>>> # set input data
>>> points = np.array([[0, 0, 1], [0, 0, -1], [1, 0, 0],
...                    [0, 1, 0], [0, -1, 0], [-1, 0, 0], ])
```

Calculate the spherical Voronoi diagram:

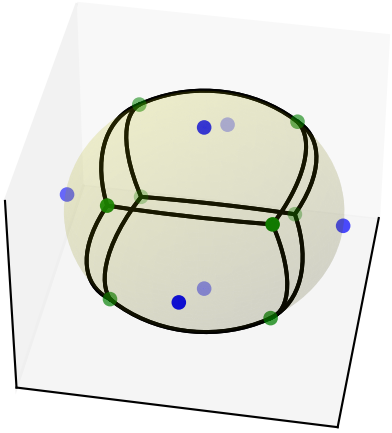
```
>>> radius = 1
>>> center = np.array([0, 0, 0])
>>> sv = SphericalVoronoi(points, radius, center)
```

Generate plot:

```
>>> # sort vertices (optional, helpful for plotting)
>>> sv.sort_vertices_of_regions()
>>> t_vals = np.linspace(0, 1, 2000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')
>>> # plot the unit sphere for reference (optional)
>>> u = np.linspace(0, 2 * np.pi, 100)
>>> v = np.linspace(0, np.pi, 100)
>>> x = np.outer(np.cos(u), np.sin(v))
>>> y = np.outer(np.sin(u), np.sin(v))
>>> z = np.outer(np.ones(np.size(u)), np.cos(v))
>>> ax.plot_surface(x, y, z, color='y', alpha=0.1)
>>> # plot generator points
>>> ax.scatter(points[:, 0], points[:, 1], points[:, 2], c='b')
>>> # plot Voronoi vertices
>>> ax.scatter(sv.vertices[:, 0], sv.vertices[:, 1], sv.vertices[:, 2],
...                    c='g')
>>> # indicate Voronoi regions (as Euclidean polygons)
>>> for region in sv.regions:
...    n = len(region)
...    for i in range(n):
...        start = sv.vertices[region][i]
...        end = sv.vertices[region][(i + 1) % n]
...        result = geometric_slerp(start, end, t_vals)
...        ax.plot(result[..., 0],
...                result[..., 1],
...                result[..., 2],
...                c='k')
>>> ax.azim = 10
>>> ax.elev = 40
>>> _ = ax.set_xticks([])
>>> _ = ax.set_yticks([])
>>> _ = ax.set_zticks([])
>>> fig.set_size_inches(4, 4)
>>> plt.show()
```

Attributes

points	[double array of shape (npoints, ndim)] the points in *ndim* dimensions to generate the Voronoi diagram from
radius	[double] radius of the sphere
center	[double array of shape (ndim,)] center of the sphere
vertices	[double array of shape (nvertices, ndim)] Voronoi vertices corresponding to points
regions	[list of list of integers of shape (npoints, _)] the n-th entry is a list consisting of the indices of the vertices belonging to the n-th point in points



Methods

calculate_areas()	Calculates the areas of the Voronoi regions.

scipy.spatial.SphericalVoronoi.calculate_areas

SphericalVoronoi.**calculate_areas**()

Calculates the areas of the Voronoi regions.

For 2D point sets, the regions are circular arcs. The sum of the areas is *2 * pi * radius*.

For 3D point sets, the regions are spherical polygons. The sum of the areas is *4 * pi * radius**2*.

New in version 1.5.0.

Returns

areas [double array of shape (npoints,)] The areas of the Voronoi regions.

scipy.spatial.HalfspaceIntersection

class scipy.spatial.**HalfspaceIntersection**(*halfspaces*, *interior_point*, *incremental=False*, *qhull_options=None*)

Halfspace intersections in N dimensions.

New in version 0.19.0.

Parameters

halfspaces [ndarray of floats, shape (nineq, ndim+1)] Stacked Inequalities of the form Ax + b <= 0 in format [A; b]

interior_point [ndarray of floats, shape (ndim,)] Point clearly inside the region defined by halfspaces. Also called a feasible point, it can be obtained by linear programming.

incremental [bool, optional] Allow adding new halfspaces incrementally. This takes up some additional resources.

Notes

The intersections are computed using the Qhull library. This reproduces the "qhalf" functionality of Qhull.

References

[Qhull], [1]

Examples

Halfspace intersection of planes forming some polygon

```
>>> from scipy.spatial import HalfspaceIntersection
>>> halfspaces = np.array([[-1, 0., 0.],
...                        [0., -1., 0.],
...                        [2., 1., -4.],
...                        [-0.5, 1., -2.]])
>>> feasible_point = np.array([0.5, 0.5])
>>> hs = HalfspaceIntersection(halfspaces, feasible_point)
```

Plot halfspaces as filled regions and intersection points:

```
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1, 1, 1, aspect='equal')
>>> xlim, ylim = (-1, 3), (-1, 3)
>>> ax.set_xlim(xlim)
>>> ax.set_ylim(ylim)
>>> x = np.linspace(-1, 3, 100)
>>> symbols = ['-', '+', 'x', '*']
>>> signs = [0, 0, -1, -1]
>>> fmt = {"color": None, "edgecolor": "b", "alpha": 0.5}
>>> for h, sym, sign in zip(halfspaces, symbols, signs):
...     hlist = h.tolist()
...     fmt["hatch"] = sym
...     if h[1]== 0:
...         ax.axvline(-h[2]/h[0], label='{}x+{}y+{}=0'.format(*hlist))
...         xi = np.linspace(xlim[sign], -h[2]/h[0], 100)
...         ax.fill_between(xi, ylim[0], ylim[1], **fmt)
...     else:
...         ax.plot(x, (-h[2]-h[0]*x)/h[1], label='{}x+{}y+{}=0'.
↪format(*hlist))
...         ax.fill_between(x, (-h[2]-h[0]*x)/h[1], ylim[sign], **fmt)
>>> x, y = zip(*hs.intersections)
>>> ax.plot(x, y, 'o', markersize=8)
```

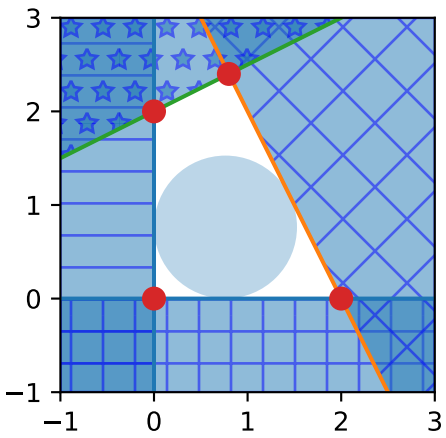
By default, qhull does not provide with a way to compute an interior point. This can easily be computed using linear programming. Considering halfspaces of the form $Ax + b \leq 0$, solving the linear program:

$$max\ y$$
$$s.t. Ax + y||A_i|| \leq -b$$

With A_i being the rows of A, i.e. the normals to each plane.

Will yield a point x that is furthest inside the convex polyhedron. To be precise, it is the center of the largest hypersphere of radius y inscribed in the polyhedron. This point is called the Chebyshev center of the polyhedron (see [1] 4.3.1, pp148-149). The equations outputted by Qhull are always normalized.

```
>>> from scipy.optimize import linprog
>>> from matplotlib.patches import Circle
>>> norm_vector = np.reshape(np.linalg.norm(halfspaces[:, :-1], axis=1),
...     (halfspaces.shape[0], 1))
>>> c = np.zeros((halfspaces.shape[1],))
>>> c[-1] = -1
>>> A = np.hstack((halfspaces[:, :-1], norm_vector))
>>> b = - halfspaces[:, -1:]
>>> res = linprog(c, A_ub=A, b_ub=b, bounds=(None, None))
>>> x = res.x[:-1]
>>> y = res.x[-1]
>>> circle = Circle(x, radius=y, alpha=0.3)
>>> ax.add_patch(circle)
>>> plt.legend(bbox_to_anchor=(1.6, 1.0))
>>> plt.show()
```



Attributes

halfspaces [ndarray of double, shape (nineq, ndim+1)] Input halfspaces.

interior_point :ndarray of floats, shape (ndim,)
Input interior point.

intersections
[ndarray of double, shape (ninter, ndim)] Intersections of all halfspaces.

dual_points
[ndarray of double, shape (nineq, ndim)] Dual points of the input halfspaces.

dual_facets
[list of lists of ints] Indices of points forming the (non necessarily simplicial) facets of the dual convex hull.

dual_vertices

[ndarray of ints, shape (nvertices,)] Indices of halfspaces forming the vertices of the dual convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.

dual_equations
[ndarray of double, shape (nfacet, ndim+1)] [normal, offset] forming the hyperplane equation of the dual facet (see Qhull documentation for more).

dual_area [float] Area of the dual convex hull

dual_volume
[float] Volume of the dual convex hull

Methods

add_halfspaces(halfspaces[, restart])	Process a set of additional new halfspaces.
close()	Finish incremental processing.

scipy.spatial.HalfspaceIntersection.add_halfspaces

HalfspaceIntersection.**add_halfspaces**(*halfspaces*, *restart=False*)

Process a set of additional new halfspaces.

Parameters

halfspaces [ndarray] New halfspaces to add. The dimensionality should match that of the initial halfspaces.

restart [bool, optional] Whether to restart processing from scratch, rather than adding halfspaces incrementally.

Raises

QhullError
Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

See also:

close

Notes

You need to specify `incremental=True` when constructing the object to be able to add halfspaces incrementally. Incremental addition of halfspaces is also not possible after *close* has been called.

scipy.spatial.HalfspaceIntersection.close

HalfspaceIntersection.**close**()

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

Plotting helpers

delaunay_plot_2d(tri[, ax])	Plot the given Delaunay triangulation in 2-D
convex_hull_plot_2d(hull[, ax])	Plot the given convex hull diagram in 2-D
voronoi_plot_2d(vor[, ax])	Plot the given Voronoi diagram in 2-D

scipy.spatial.delaunay_plot_2d

scipy.spatial.**delaunay_plot_2d**(*tri*, *ax=None*)

Plot the given Delaunay triangulation in 2-D

Parameters

tri [scipy.spatial.Delaunay instance] Triangulation to plot

ax [matplotlib.axes.Axes instance, optional] Axes to plot on

Returns

fig [matplotlib.figure.Figure instance] Figure for the plot

See also:

Delaunay

matplotlib.pyplot.triplot

Notes

Requires Matplotlib.

Examples

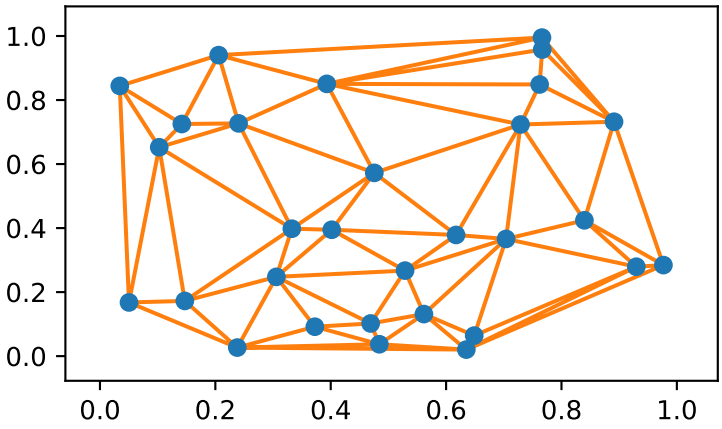
```
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import Delaunay, delaunay_plot_2d
```

The Delaunay triangulation of a set of random points:

```
>>> rng = np.random.default_rng()
>>> points = rng.random((30, 2))
>>> tri = Delaunay(points)
```

Plot it:

```
>>> _ = delaunay_plot_2d(tri)
>>> plt.show()
```



scipy.spatial.convex_hull_plot_2d

scipy.spatial.**convex_hull_plot_2d**(*hull*, *ax=None*)

Plot the given convex hull diagram in 2-D

Parameters

hull	[scipy.spatial.ConvexHull instance] Convex hull to plot
ax	[matplotlib.axes.Axes instance, optional] Axes to plot on

Returns

fig	[matplotlib.figure.Figure instance] Figure for the plot

See also:

`ConvexHull`

Notes

Requires Matplotlib.

Examples

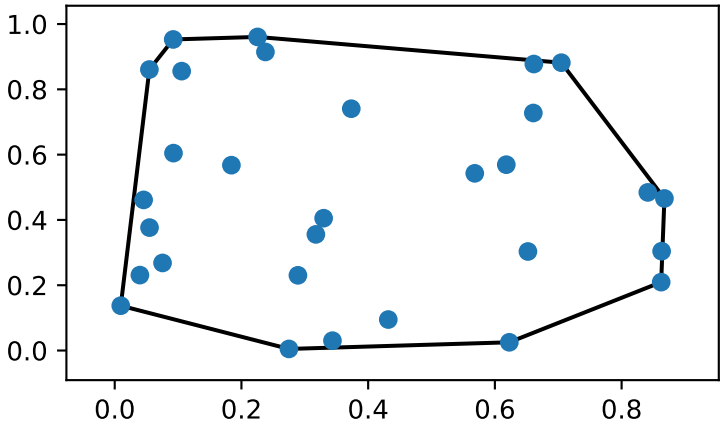
```
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import ConvexHull, convex_hull_plot_2d
```

The convex hull of a random set of points:

```
>>> rng = np.random.default_rng()
>>> points = rng.random((30, 2))
>>> hull = ConvexHull(points)
```

Plot it:

```
>>> _ = convex_hull_plot_2d(hull)
>>> plt.show()
```



scipy.spatial.voronoi_plot_2d

scipy.spatial.**voronoi_plot_2d**(*vor*, *ax=None*, ***kw*)

Plot the given Voronoi diagram in 2-D

Parameters

vor [scipy.spatial.Voronoi instance] Diagram to plot

ax [matplotlib.axes.Axes instance, optional] Axes to plot on

show_points: bool, optional
Add the Voronoi points to the plot.

show_vertices
[bool, optional] Add the Voronoi vertices to the plot.

line_colors
[string, optional] Specifies the line color for polygon boundaries

line_width [float, optional] Specifies the line width for polygon boundaries

line_alpha: float, optional
Specifies the line alpha for polygon boundaries

point_size: float, optional
Specifies the size of points

Returns

fig [matplotlib.figure.Figure instance] Figure for the plot

See also:

Voronoi

Notes

Requires Matplotlib.

Examples

Set of point:

```
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> points = rng.random((10,2))
```

Voronoi diagram of the points:

```
>>> from scipy.spatial import Voronoi, voronoi_plot_2d
>>> vor = Voronoi(points)
```

using *voronoi_plot_2d* for visualisation:

```
>>> fig = voronoi_plot_2d(vor)
```

using *voronoi_plot_2d* for visualisation with enhancements:

```
>>> fig = voronoi_plot_2d(vor, show_vertices=False, line_colors='orange',
...                       line_width=2, line_alpha=0.6, point_size=2)
>>> plt.show()
```

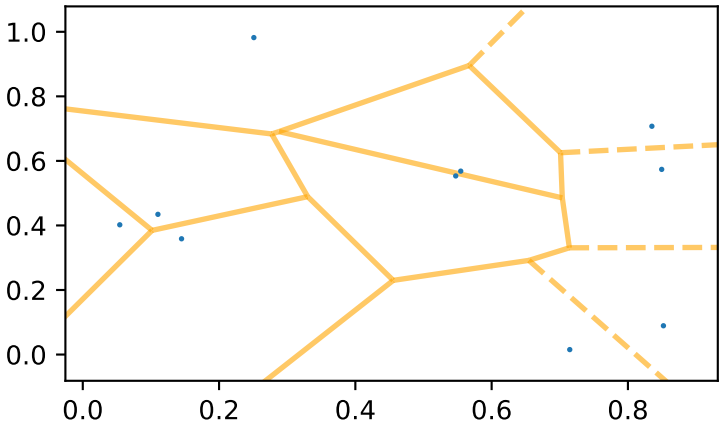
Tutorial



Simplex representation

The simplices (triangles, tetrahedra, etc.) appearing in the Delaunay tessellation (N-D simplices), convex hull facets, and Voronoi ridges (N-1-D simplices) are represented in the following scheme:

```
tess = Delaunay(points)
hull = ConvexHull(points)
voro = Voronoi(points)

# coordinates of the jth vertex of the ith simplex
tess.points[tess.simplices[i, j], :]        # tessellation element
hull.points[hull.simplices[i, j], :]        # convex hull facet
voro.vertices[voro.ridge_vertices[i, j], :] # ridge between Voronoi cells
```

For Delaunay triangulations and convex hulls, the neighborhood structure of the simplices satisfies the condition: `tess.neighbors[i,j]` is the neighboring simplex of the ith simplex, opposite to the `j`-vertex. It is -1 in case of no neighbor.

Convex hull facets also define a hyperplane equation:

```
(hull.equations[i,:-1] * coord).sum() + hull.equations[i,-1] == 0
```

Similar hyperplane equations for the Delaunay triangulation correspond to the convex hull facets on the corresponding N+1-D paraboloid.

The Delaunay triangulation objects offer a method for locating the simplex containing a given point, and barycentric coordinate computations.

Functions

tsearch(tri, xi)	Find simplices containing the given points.
distance_matrix(x, y[, p, threshold])	Compute the distance matrix.
minkowski_distance(x, y[, p])	Compute the L**p distance between two arrays.
minkowski_distance_p(x, y[, p])	Compute the pth power of the L**p distance between two arrays.
procrustes(data1, data2)	Procrustes analysis, a similarity test for two data sets.
geometric_slerp(start, end, t[, tol])	Geometric spherical linear interpolation.

scipy.spatial.tsearch

scipy.spatial.**tsearch**(*tri*, *xi*)

Find simplices containing the given points. This function does the same thing as *Delaunay.find_simplex*.

New in version 0.9.

See also:

Delaunay.find_simplex

Examples

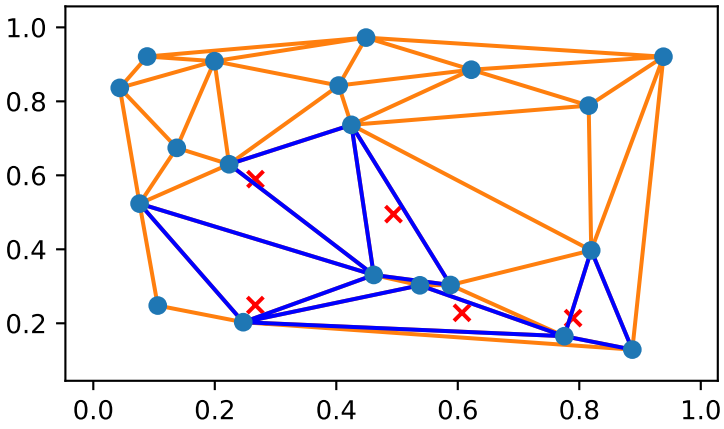
```
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import Delaunay, delaunay_plot_2d, tsearch
>>> rng = np.random.default_rng()
```

The Delaunay triangulation of a set of random points:

```
>>> pts = rng.random((20, 2))
>>> tri = Delaunay(pts)
>>> _ = delaunay_plot_2d(tri)
```

Find the simplices containing a given set of points:

```
>>> loc = rng.uniform(0.2, 0.8, (5, 2))
>>> s = tsearch(tri, loc)
>>> plt.triplot(pts[:, 0], pts[:, 1], tri.simplices[s], 'b-', mask=s==-1)
>>> plt.scatter(loc[:, 0], loc[:, 1], c='r', marker='x')
>>> plt.show()
```



scipy.spatial.distance_matrix

scipy.spatial.**distance_matrix**(*x*, *y*, *p=2*, *threshold=1000000*)

Compute the distance matrix.

Returns the matrix of all pair-wise distances.

Parameters

x	[(M, K) array_like] Matrix of M vectors in K dimensions.
y	[(N, K) array_like] Matrix of N vectors in K dimensions.
p	[float, 1 <= p <= infinity] Which Minkowski p-norm to use.
threshold	[positive int] If `M * N * K` > *threshold*, algorithm uses a Python loop instead of large temporary arrays.

Returns

result	[(M, N) ndarray] Matrix containing the distance from every vector in *x* to every vector in *y*.

Examples

```
>>> from scipy.spatial import distance_matrix
>>> distance_matrix([[0,0],[0,1]], [[1,0],[1,1]])
array([[ 1.        ,  1.41421356],
       [ 1.41421356,  1.        ]])
```

scipy.spatial.minkowski_distance

scipy.spatial.**minkowski_distance**(*x*, *y*, *p=2*)

Compute the L**p distance between two arrays.

Parameters

x	[(M, K) array_like] Input array.
y	[(N, K) array_like] Input array.
p	[float, 1 <= p <= infinity] Which Minkowski p-norm to use.

Examples

```
>>> from scipy.spatial import minkowski_distance
>>> minkowski_distance([[0,0],[0,0]], [[1,1],[0,1]])
array([ 1.41421356,  1.        ])
```

scipy.spatial.minkowski_distance_p

scipy.spatial.**minkowski_distance_p**(*x*, *y*, *p=2*)

Compute the pth power of the L**p distance between two arrays.

For efficiency, this function computes the L**p distance but does not extract the pth root. If *p* is 1 or infinity, this is equal to the actual L**p distance.

Parameters

x	[(M, K) array_like] Input array.
y	[(N, K) array_like] Input array.
p	[float, 1 <= p <= infinity] Which Minkowski p-norm to use.

Examples

```
>>> from scipy.spatial import minkowski_distance_p
>>> minkowski_distance_p([[0,0],[0,0]], [[1,1],[0,1]])
array([2, 1])
```

scipy.spatial.procrustes

scipy.spatial.**procrustes**(*data1*, *data2*)

Procrustes analysis, a similarity test for two data sets.

Each input matrix is a set of points or vectors (the rows of the matrix). The dimension of the space is the number of columns of each matrix. Given two identically sized matrices, procrustes standardizes both such that:

- $tr(AA^T) = 1$.
- Both sets of points are centered around the origin.

Procrustes ([1], [2]) then applies the optimal transform to the second matrix (including scaling/dilation, rotations, and reflections) to minimize $M^2 = \sum(data1 - data2)^2$, or the sum of the squares of the pointwise differences between the two input datasets.

This function was not designed to handle datasets with different numbers of datapoints (rows). If two data sets have different dimensionality (different number of columns), simply add columns of zeros to the smaller of the two.

Parameters

data1 [array_like] Matrix, n rows represent points in k (columns) space *data1* is the reference data, after it is standardised, the data from *data2* will be transformed to fit the pattern in *data1* (must have >1 unique points).

data2 [array_like] n rows of data in k space to be fit to *data1*. Must be the same shape `(numrows, numcols)` as data1 (must have >1 unique points).

Returns

mtx1 [array_like] A standardized version of *data1*.

mtx2 [array_like] The orientation of *data2* that best fits *data1*. Centered, but not necessarily $tr(AA^T) = 1$.

disparity [float] M^2 as defined above.

Raises

ValueError If the input arrays are not two-dimensional. If the shape of the input arrays is different. If the input arrays have zero columns or zero rows.

See also:

`scipy.linalg.orthogonal_procrustes`

`scipy.spatial.distance.directed_hausdorff`

Another similarity test for two data sets

Notes

- The disparity should not depend on the order of the input matrices, but the output matrices will, as only the first output matrix is guaranteed to be scaled such that $tr(AA^T) = 1$.
- Duplicate data points are generally ok, duplicating a data point will increase its effect on the procrustes fit.
- The disparity scales as the number of points per input matrix.

References

[1], [2]

Examples

```
>>> from scipy.spatial import procrustes
```

The matrix `b` is a rotated, shifted, scaled and mirrored version of `a` here:

```
>>> a = np.array([[1, 3], [1, 2], [1, 1], [2, 1]], 'd')
>>> b = np.array([[4, -2], [4, -4], [4, -6], [2, -6]], 'd')
>>> mtx1, mtx2, disparity = procrustes(a, b)
>>> round(disparity)
0.0
```

scipy.spatial.geometric_slerp

scipy.spatial.**geometric_slerp**(*start*, *end*, *t*, *tol=1e-07*)

Geometric spherical linear interpolation.

The interpolation occurs along a unit-radius great circle arc in arbitrary dimensional space.

Parameters

start [(n_dimensions,) array-like] Single n-dimensional input coordinate in a 1-D array-like object. *n* must be greater than 1.

end [(n_dimensions,) array-like] Single n-dimensional input coordinate in a 1-D array-like object. *n* must be greater than 1.

t: float or (n_points,) array-like
A float or array-like of doubles representing interpolation parameters, with values required in the inclusive interval between 0 and 1. A common approach is to generate the array with `np.linspace(0, 1, n_pts)` for linearly spaced points. Ascending, descending, and scrambled orders are permitted.

tol: float The absolute tolerance for determining if the start and end coordinates are antipodes.

Returns

result [(t.size, D)] An array of doubles containing the interpolated spherical path and including start and end when 0 and 1 t are used. The interpolated values should correspond to the same sort order provided in the t array. The result may be 1-dimensional if `t` is a float.

Raises

ValueError
If `start` and `end` are antipodes, not on the unit n-sphere, or for a variety of degenerate conditions.

See also:

scipy.spatial.transform.Slerp

3-D Slerp that works with quaternions

Notes

The implementation is based on the mathematical formula provided in [1], and the first known presentation of this algorithm, derived from study of 4-D geometry, is credited to Glenn Davis in a footnote of the original quaternion Slerp publication by Ken Shoemake [2].

New in version 1.5.0.

References

[1], [2]

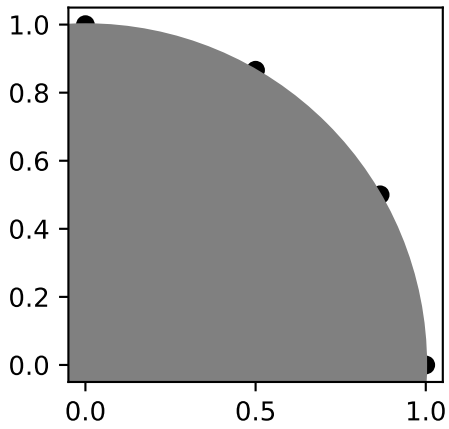
Examples

Interpolate four linearly-spaced values on the circumference of a circle spanning 90 degrees:

```
>>> from scipy.spatial import geometric_slerp
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> start = np.array([1, 0])
>>> end = np.array([0, 1])
>>> t_vals = np.linspace(0, 1, 4)
>>> result = geometric_slerp(start,
...                          end,
...                          t_vals)
```

The interpolated results should be at 30 degree intervals recognizable on the unit circle:

```
>>> ax.scatter(result[...,0], result[...,1], c='k')
>>> circle = plt.Circle((0, 0), 1, color='grey')
>>> ax.add_artist(circle)
>>> ax.set_aspect('equal')
>>> plt.show()
```



Attempting to interpolate between antipodes on a circle is ambiguous because there are two possible paths, and on a sphere there are infinite possible paths on the geodesic surface. Nonetheless, one of the ambiguous paths is returned along with a warning:

```
>>> opposite_pole = np.array([-1, 0])
>>> with np.testing.suppress_warnings() as sup:
...     sup.filter(UserWarning)
...     geometric_slerp(start,
...                     opposite_pole,
...                     t_vals)
array([[ 1.00000000e+00,  0.00000000e+00],
```

(continues on next page)

(continued from previous page)

```
       [ 5.00000000e-01,  8.66025404e-01],
       [-5.00000000e-01,  8.66025404e-01],
       [-1.00000000e+00,  1.22464680e-16]])
```

Extend the original example to a sphere and plot interpolation points in 3D:

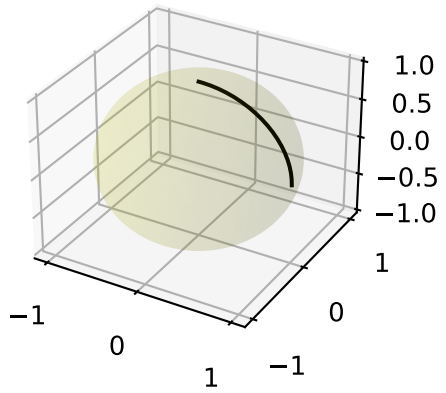
```
>>> from mpl_toolkits.mplot3d import proj3d
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')
```

Plot the unit sphere for reference (optional):

```
>>> u = np.linspace(0, 2 * np.pi, 100)
>>> v = np.linspace(0, np.pi, 100)
>>> x = np.outer(np.cos(u), np.sin(v))
>>> y = np.outer(np.sin(u), np.sin(v))
>>> z = np.outer(np.ones(np.size(u)), np.cos(v))
>>> ax.plot_surface(x, y, z, color='y', alpha=0.1)
```

Interpolating over a larger number of points may provide the appearance of a smooth curve on the surface of the sphere, which is also useful for discretized integration calculations on a sphere surface:

```
>>> start = np.array([1, 0, 0])
>>> end = np.array([0, 0, 1])
>>> t_vals = np.linspace(0, 1, 200)
>>> result = geometric_slerp(start,
...                          end,
...                          t_vals)
>>> ax.plot(result[...,0],
...         result[...,1],
...         result[...,2],
...         c='k')
>>> plt.show()
```



3.3.27 Distance computations (scipy.spatial.distance)

Function reference

Distance matrix computation from a collection of raw observation vectors stored in a rectangular array.

pdist(X[, metric, out])	Pairwise distances between observations in n-dimensional space.
cdist(XA, XB[, metric, out])	Compute distance between each pair of the two collections of inputs.
squareform(X[, force, checks])	Convert a vector-form distance vector to a square-form distance matrix, and vice-versa.
directed_hausdorff(u, v[, seed])	Compute the directed Hausdorff distance between two N-D arrays.

scipy.spatial.distance.pdist

scipy.spatial.distance.**pdist**(*X*, *metric='euclidean'*, ***, *out=None*, ***kwargs*)

Pairwise distances between observations in n-dimensional space.

See Notes for common calling conventions.

Parameters

X [array_like] An m by n array of m original observations in an n-dimensional space.

metric [str or function, optional] The distance metric to use. The distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'jensenshannon', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'.

****kwargs** [dict, optional] Extra arguments to *metric*: refer to each metric documentation for a list of all possible arguments.
Some possible arguments:
p : scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.
w : ndarray The weight vector for metrics that support weights (e.g., Minkowski).
V : ndarray The variance vector for standardized Euclidean. Default: var(X, axis=0, ddof=1)
VI : ndarray The inverse of the covariance matrix for Mahalanobis. Default: inv(cov(X.T)).T
out : ndarray. The output array If not None, condensed distance matrix Y is stored in this array.

Returns

Y [ndarray] Returns a condensed distance matrix Y. For each i and j (where $i < j < m$),where m is the number of original observations. The metric `dist(u=X[i], v=X[j])` is computed and stored in entry `m * i + j - ((i + 2) * (i + 1)) // 2`.

See also:

squareform

converts between condensed distance matrices and square distance matrices.

Notes

See `squareform` for information on how to calculate the index of this entry or to convert the condensed distance matrix to a redundant square matrix.

The following are common calling conventions.

1. `Y = pdist(X, 'euclidean')`

   Computes the distance between m points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as m n-dimensional row vectors in the matrix X.

2. `Y = pdist(X, 'minkowski', p=2.)`

   Computes the distances using the Minkowski distance $||u-v||_p$ (p-norm) where $p \geq 1$.

3. `Y = pdist(X, 'cityblock')`

   Computes the city block or Manhattan distance between the points.

4. `Y = pdist(X, 'seuclidean', V=None)`

   Computes the standardized Euclidean distance. The standardized Euclidean distance between two n-vectors `u` and `v` is

   $$\sqrt{\sum (u_i - v_i)^2 / V[x_i]}$$

   V is the variance vector; V[i] is the variance computed over all the i'th components of the points. If not passed, it is automatically computed.

5. `Y = pdist(X, 'sqeuclidean')`

   Computes the squared Euclidean distance $||u-v||_2^2$ between the vectors.

6. `Y = pdist(X, 'cosine')`

   Computes the cosine distance between vectors u and v,

   $$1 - \frac{u \cdot v}{||u||_2 ||v||_2}$$

   where $||*||_2$ is the 2-norm of its argument `*`, and $u \cdot v$ is the dot product of `u` and `v`.

7. `Y = pdist(X, 'correlation')`

   Computes the correlation distance between vectors u and v. This is

   $$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{||(u - \bar{u})||_2 ||(v - \bar{v})||_2}$$

   where $\bar{v}$ is the mean of the elements of vector v, and $x \cdot y$ is the dot product of x and y.

8. `Y = pdist(X, 'hamming')`

   Computes the normalized Hamming distance, or the proportion of those vector elements between two n-vectors `u` and `v` which disagree. To save memory, the matrix `X` can be of type boolean.

9. `Y = pdist(X, 'jaccard')`

   Computes the Jaccard distance between the points. Given two vectors, `u` and `v`, the Jaccard distance is the proportion of those elements `u[i]` and `v[i]` that disagree.

10. `Y = pdist(X, 'jensenshannon')`

Computes the Jensen-Shannon distance between two probability arrays. Given two probability vectors, p and q, the Jensen-Shannon distance is

$$\sqrt{\frac{D(p \parallel m) + D(q \parallel m)}{2}}$$

where m is the pointwise mean of p and q and D is the Kullback-Leibler divergence.

11. `Y = pdist(X, 'chebyshev')`

    Computes the Chebyshev distance between the points. The Chebyshev distance between two n-vectors `u` and `v` is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

    $$d(u, v) = \max_i |u_i - v_i|$$

12. `Y = pdist(X, 'canberra')`

    Computes the Canberra distance between the points. The Canberra distance between two points `u` and `v` is

    $$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}$$

13. `Y = pdist(X, 'braycurtis')`

    Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points `u` and `v` is

    $$d(u, v) = \frac{\sum_i |u_i - v_i|}{\sum_i |u_i + v_i|}$$

14. `Y = pdist(X, 'mahalanobis', VI=None)`

    Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points `u` and `v` is $\sqrt{(u - v)(1/V)(u - v)^T}$ where $(1/V)$ (the `VI` variable) is the inverse covariance. If `VI` is not None, `VI` will be used as the inverse covariance matrix.

15. `Y = pdist(X, 'yule')`

    Computes the Yule distance between each pair of boolean vectors. (see yule function documentation)

16. `Y = pdist(X, 'matching')`

    Synonym for 'hamming'.

17. `Y = pdist(X, 'dice')`

    Computes the Dice distance between each pair of boolean vectors. (see dice function documentation)

18. `Y = pdist(X, 'kulsinski')`

    Computes the Kulsinski distance between each pair of boolean vectors. (see kulsinski function documentation)

19. `Y = pdist(X, 'rogerstanimoto')`

    Computes the Rogers-Tanimoto distance between each pair of boolean vectors. (see rogerstanimoto function documentation)

20. `Y = pdist(X, 'russellrao')`

    Computes the Russell-Rao distance between each pair of boolean vectors. (see russellrao function documentation)

21. `Y = pdist(X, 'sokalmichener')`

    Computes the Sokal-Michener distance between each pair of boolean vectors. (see sokalmichener function documentation)

22. `Y = pdist(X, 'sokalsneath')`

    Computes the Sokal-Sneath distance between each pair of boolean vectors. (see sokalsneath function documentation)

23. `Y = pdist(X, 'wminkowski', p=2, w=w)`

    Computes the weighted Minkowski distance between each pair of vectors. (see wminkowski function documentation)

    'wminkowski' is deprecated and will be removed in SciPy 1.8.0. Use 'minkowski' instead.

24. `Y = pdist(X, f)`

    Computes the distance between all pairs of vectors in X using the user supplied 2-arity function f. For example, Euclidean distance between the vectors could be computed as follows:

    ```
    dm = pdist(X, lambda u, v: np.sqrt(((u-v)**2).sum()))
    ```

    Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

    ```
    dm = pdist(X, sokalsneath)
    ```

    would calculate the pair-wise distances between the vectors in X using the Python function sokalsneath. This would result in sokalsneath being called $\binom{n}{2}$ times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax.:

    ```
    dm = pdist(X, 'sokalsneath')
    ```

scipy.spatial.distance.cdist

scipy.spatial.distance.**cdist**(*XA*, *XB*, *metric='euclidean'*, ***, *out=None*, ***kwargs*)

Compute distance between each pair of the two collections of inputs.

See Notes for common calling conventions.

Parameters

XA [array_like] An m_A by n array of m_A original observations in an n-dimensional space. Inputs are converted to float type.

XB [array_like] An m_B by n array of m_B original observations in an n-dimensional space. Inputs are converted to float type.

metric [str or callable, optional] The distance metric to use. If a string, the distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'jensenshannon', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'wminkowski', 'yule'.

****kwargs** [dict, optional] Extra arguments to *metric*: refer to each metric documentation for a list of all possible arguments.
Some possible arguments:
p : scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.
w : array_like The weight vector for metrics that support weights (e.g., Minkowski).
V : array_like The variance vector for standardized Euclidean. Default: var(vstack([XA, XB]), axis=0, ddof=1)

VI : array_like The inverse of the covariance matrix for Mahalanobis. Default: inv(cov(vstack([XA, XB].T))).T
out : ndarray The output array If not None, the distance matrix Y is stored in this array.

Returns

Y [ndarray] A m_A by m_B distance matrix is returned. For each i and j, the metric `dist(u=XA[i], v=XB[j])` is computed and stored in the ij th entry.

Raises

ValueError
An exception is thrown if *XA* and *XB* do not have the same number of columns.

Notes

The following are common calling conventions:

1. `Y = cdist(XA, XB, 'euclidean')`

   Computes the distance between m points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as m n-dimensional row vectors in the matrix X.

2. `Y = cdist(XA, XB, 'minkowski', p=2.)`

   Computes the distances using the Minkowski distance $||u-v||_p$ (p-norm) where $p \geq 1$.

3. `Y = cdist(XA, XB, 'cityblock')`

   Computes the city block or Manhattan distance between the points.

4. `Y = cdist(XA, XB, 'seuclidean', V=None)`

   Computes the standardized Euclidean distance. The standardized Euclidean distance between two n-vectors `u` and `v` is

   $$\sqrt{\sum (u_i - v_i)^2 / V[x_i]}.$$

   V is the variance vector; V[i] is the variance computed over all the i'th components of the points. If not passed, it is automatically computed.

5. `Y = cdist(XA, XB, 'sqeuclidean')`

   Computes the squared Euclidean distance $||u-v||_2^2$ between the vectors.

6. `Y = cdist(XA, XB, 'cosine')`

   Computes the cosine distance between vectors u and v,

   $$1 - \frac{u \cdot v}{||u||_2 ||v||_2}$$

   where $||*||_2$ is the 2-norm of its argument `*`, and $u \cdot v$ is the dot product of u and v.

7. `Y = cdist(XA, XB, 'correlation')`

   Computes the correlation distance between vectors u and v. This is

   $$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{||(u - \bar{u})||_2 ||(v - \bar{v})||_2}$$

   where $\bar{v}$ is the mean of the elements of vector v, and $x \cdot y$ is the dot product of x and y.

8. `Y = cdist(XA, XB, 'hamming')`

   Computes the normalized Hamming distance, or the proportion of those vector elements between two n-vectors `u` and `v` which disagree. To save memory, the matrix `X` can be of type boolean.

9. `Y = cdist(XA, XB, 'jaccard')`

   Computes the Jaccard distance between the points. Given two vectors, `u` and `v`, the Jaccard distance is the proportion of those elements `u[i]` and `v[i]` that disagree where at least one of them is non-zero.

10. `Y = cdist(XA, XB, 'jensenshannon')`

    Computes the Jensen-Shannon distance between two probability arrays. Given two probability vectors, p and q, the Jensen-Shannon distance is

    $$\sqrt{\frac{D(p \parallel m) + D(q \parallel m)}{2}}$$

    where m is the pointwise mean of p and q and D is the Kullback-Leibler divergence.

11. `Y = cdist(XA, XB, 'chebyshev')`

    Computes the Chebyshev distance between the points. The Chebyshev distance between two n-vectors `u` and `v` is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

    $$d(u, v) = \max_i |u_i - v_i|.$$

12. `Y = cdist(XA, XB, 'canberra')`

    Computes the Canberra distance between the points. The Canberra distance between two points `u` and `v` is

    $$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}.$$

13. `Y = cdist(XA, XB, 'braycurtis')`

    Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points `u` and `v` is

    $$d(u, v) = \frac{\sum_i (|u_i - v_i|)}{\sum_i (|u_i + v_i|)}$$

14. `Y = cdist(XA, XB, 'mahalanobis', VI=None)`

    Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points `u` and `v` is $\sqrt{(u - v)(1/V)(u - v)^T}$ where $(1/V)$ (the `VI` variable) is the inverse covariance. If `VI` is not None, `VI` will be used as the inverse covariance matrix.

15. `Y = cdist(XA, XB, 'yule')`

    Computes the Yule distance between the boolean vectors. (see *yule* function documentation)

16. `Y = cdist(XA, XB, 'matching')`

    Synonym for 'hamming'.

17. `Y = cdist(XA, XB, 'dice')`

    Computes the Dice distance between the boolean vectors. (see *dice* function documentation)

18. `Y = cdist(XA, XB, 'kulsinski')`

    Computes the Kulsinski distance between the boolean vectors. (see *kulsinski* function documentation)

19. `Y = cdist(XA, XB, 'rogerstanimoto')`

    Computes the Rogers-Tanimoto distance between the boolean vectors. (see *rogerstanimoto* function documentation)

20. `Y = cdist(XA, XB, 'russellrao')`

    Computes the Russell-Rao distance between the boolean vectors. (see *russellrao* function documentation)

21. `Y = cdist(XA, XB, 'sokalmichener')`

    Computes the Sokal-Michener distance between the boolean vectors. (see *sokalmichener* function documentation)

22. `Y = cdist(XA, XB, 'sokalsneath')`

    Computes the Sokal-Sneath distance between the vectors. (see *sokalsneath* function documentation)

23. `Y = cdist(XA, XB, 'wminkowski', p=2., w=w)`

    Computes the weighted Minkowski distance between the vectors. (see *wminkowski* function documentation)

    'wminkowski' is deprecated and will be removed in SciPy 1.8.0. Use 'minkowski' instead.

24. `Y = cdist(XA, XB, f)`

    Computes the distance between all pairs of vectors in X using the user supplied 2-arity function f. For example, Euclidean distance between the vectors could be computed as follows:

    ```
    dm = cdist(XA, XB, lambda u, v: np.sqrt(((u-v)**2).sum()))
    ```

    Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

    ```
    dm = cdist(XA, XB, sokalsneath)
    ```

    would calculate the pair-wise distances between the vectors in X using the Python function *sokalsneath*. This would result in sokalsneath being called $\binom{n}{2}$ times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax:

    ```
    dm = cdist(XA, XB, 'sokalsneath')
    ```

Examples

Find the Euclidean distances between four 2-D coordinates:

```
>>> from scipy.spatial import distance
>>> coords = [(35.0456, -85.2672),
...           (35.1174, -89.9711),
...           (35.9728, -83.9422),
...           (36.1667, -86.7833)]
>>> distance.cdist(coords, coords, 'euclidean')
array([[ 0.    ,  4.7044,  1.6172,  1.8856],
       [ 4.7044,  0.    ,  6.0893,  3.3561],
       [ 1.6172,  6.0893,  0.    ,  2.8477],
       [ 1.8856,  3.3561,  2.8477,  0.    ]])
```

Find the Manhattan distance from a 3-D point to the corners of the unit cube:

```
>>> a = np.array([[0, 0, 0],
...               [0, 0, 1],
...               [0, 1, 0],
...               [0, 1, 1],
...               [1, 0, 0],
...               [1, 0, 1],
...               [1, 1, 0],
...               [1, 1, 1]])
>>> b = np.array([[ 0.1,  0.2,  0.4]])
>>> distance.cdist(a, b, 'cityblock')
array([[ 0.7],
       [ 0.9],
       [ 1.3],
       [ 1.5],
       [ 1.5],
       [ 1.7],
       [ 2.1],
       [ 2.3]])
```

scipy.spatial.distance.squareform

scipy.spatial.distance.**squareform**(*X*, *force='no'*, *checks=True*)

Convert a vector-form distance vector to a square-form distance matrix, and vice-versa.

Parameters

X [array_like] Either a condensed or redundant distance matrix.

force [str, optional] As with MATLAB(TM), if force is equal to `'tovector'` or `'tomatrix'`, the input will be treated as a distance matrix or distance vector respectively.

checks [bool, optional] If set to False, no checks will be made for matrix symmetry nor zero diagonals. This is useful if it is known that `X - X.T1` is small and `diag(X)` is close to zero. These values are ignored any way so they do not disrupt the squareform transformation.

Returns

Y [ndarray] If a condensed distance matrix is passed, a redundant one is returned, or if a redundant one is passed, a condensed distance matrix is returned.

Notes

1. `v = squareform(X)`

   Given a square n-by-n symmetric distance matrix `X`, `v = squareform(X)` returns a `n * (n-1) / 2` (i.e. binomial coefficient n choose 2) sized vector *v* where $v[\binom{n}{2} - \binom{n-i}{2} + (j - i - 1)]$ is the distance between distinct points `i` and `j`. If `X` is non-square or asymmetric, an error is raised.

2. `X = squareform(v)`

   Given a `n * (n-1) / 2` sized vector `v` for some integer `n >= 1` encoding distances as described, `X = squareform(v)` returns a n-by-n distance matrix `X`. The `X[i, j]` and `X[j, i]` values are set to $v[\binom{n}{2} - \binom{n-i}{2} + (j - i - 1)]$ and all diagonal elements are zero.

In SciPy 0.19.0, `squareform` stopped casting all input types to float64, and started returning arrays of the same dtype as the input.

scipy.spatial.distance.directed_hausdorff

scipy.spatial.distance.**directed_hausdorff**(*u*, *v*, *seed=0*)

Compute the directed Hausdorff distance between two N-D arrays.

Distances between pairs are calculated using a Euclidean metric.

Parameters

u	[(M,N) array_like] Input array.
v	[(O,N) array_like] Input array.
seed	[int or None] Local `numpy.random.RandomState` seed. Default is 0, a random shuffling of u and v that guarantees reproducibility.

Returns

d	[double] The directed Hausdorff distance between arrays *u* and *v*,
index_1	[int] index of point contributing to Hausdorff pair in *u*
index_2	[int] index of point contributing to Hausdorff pair in *v*

Raises

ValueError
An exception is thrown if *u* and *v* do not have the same number of columns.

See also:

scipy.spatial.procrustes

Another similarity test for two data sets

Notes

Uses the early break technique and the random sampling approach described by [1]. Although worst-case performance is `O(m * o)` (as with the brute force algorithm), this is unlikely in practice as the input data would have to require the algorithm to explore every single point interaction, and after the algorithm shuffles the input points at that. The best case performance is O(m), which is satisfied by selecting an inner loop distance that is less than cmax and leads to an early break as often as possible. The authors have formally shown that the average runtime is closer to O(m).

New in version 0.19.0.

References

[1]

Examples

Find the directed Hausdorff distance between two 2-D arrays of coordinates:

```
>>> from scipy.spatial.distance import directed_hausdorff
>>> u = np.array([(1.0, 0.0),
...               (0.0, 1.0),
...               (-1.0, 0.0),
...               (0.0, -1.0)])
>>> v = np.array([(2.0, 0.0),
```

(continues on next page)

(continued from previous page)

```
...                 (0.0, 2.0),
...                 (-2.0, 0.0),
...                 (0.0, -4.0)])
```

```
>>> directed_hausdorff(u, v)[0]
2.23606797749979
>>> directed_hausdorff(v, u)[0]
3.0
```

Find the general (symmetric) Hausdorff distance between two 2-D arrays of coordinates:

```
>>> max(directed_hausdorff(u, v)[0], directed_hausdorff(v, u)[0])
3.0
```

Find the indices of the points that generate the Hausdorff distance (the Hausdorff pair):

```
>>> directed_hausdorff(v, u)[1:]
(3, 3)
```

Predicates for checking the validity of distance matrices, both condensed and redundant. Also contained in this module are functions for computing the number of observations in a distance matrix.

is_valid_dm(D[, tol, throw, name, warning])	Return True if input array is a valid distance matrix.
is_valid_y(y[, warning, throw, name])	Return True if the input array is a valid condensed distance matrix.
num_obs_dm(d)	Return the number of original observations that correspond to a square, redundant distance matrix.
num_obs_y(Y)	Return the number of original observations that correspond to a condensed distance matrix.

scipy.spatial.distance.is_valid_dm

scipy.spatial.distance.**is_valid_dm**(*D*, *tol=0.0*, *throw=False*, *name='D'*, *warning=False*)

Return True if input array is a valid distance matrix.

Distance matrices must be 2-dimensional numpy arrays. They must have a zero-diagonal, and they must be symmetric.

Parameters

D	[array_like] The candidate object to test for validity.
tol	[float, optional] The distance matrix should be symmetric. *tol* is the maximum difference between entries `ij` and `ji` for the distance metric to be considered symmetric.
throw	[bool, optional] An exception is thrown if the distance matrix passed is not valid.
name	[str, optional] The name of the variable to checked. This is useful if throw is set to True so the offending variable can be identified in the exception message when an exception is thrown.
warning	[bool, optional] Instead of throwing an exception, a warning message is raised.

Returns

valid	[bool] True if the variable *D* passed is a valid distance matrix.

Notes

Small numerical differences in *D* and *D.T* and non-zeroness of the diagonal are ignored if they are within the tolerance specified by *tol*.

scipy.spatial.distance.is_valid_y

scipy.spatial.distance.**is_valid_y**(*y*, *warning=False*, *throw=False*, *name=None*)

Return True if the input array is a valid condensed distance matrix.

Condensed distance matrices must be 1-dimensional numpy arrays. Their length must be a binomial coefficient $\binom{n}{2}$ for some positive integer n.

Parameters

y [array_like] The condensed distance matrix.

warning [bool, optional] Invokes a warning if the variable passed is not a valid condensed distance matrix. The warning message explains why the distance matrix is not valid. *name* is used when referencing the offending variable.

throw [bool, optional] Throws an exception if the variable passed is not a valid condensed distance matrix.

name [bool, optional] Used when referencing the offending variable in the warning or exception message.

scipy.spatial.distance.num_obs_dm

scipy.spatial.distance.**num_obs_dm**(*d*)

Return the number of original observations that correspond to a square, redundant distance matrix.

Parameters

d [array_like] The target distance matrix.

Returns

num_obs_dm

[int] The number of observations in the redundant distance matrix.

scipy.spatial.distance.num_obs_y

scipy.spatial.distance.**num_obs_y**(*Y*)

Return the number of original observations that correspond to a condensed distance matrix.

Parameters

Y [array_like] Condensed distance matrix.

Returns

n [int] The number of observations in the condensed distance matrix *Y*.

Distance functions between two numeric vectors `u` and `v`. Computing distances over a large collection of vectors is inefficient for these functions. Use `pdist` for this purpose.

braycurtis(u, v[, w])	Compute the Bray-Curtis distance between two 1-D arrays.
canberra(u, v[, w])	Compute the Canberra distance between two 1-D arrays.
chebyshev(u, v[, w])	Compute the Chebyshev distance.
cityblock(u, v[, w])	Compute the City Block (Manhattan) distance.

continues on next page

Table 217 – continued from previous page

correlation(u, v[, w, centered])	Compute the correlation distance between two 1-D arrays.
cosine(u, v[, w])	Compute the Cosine distance between 1-D arrays.
euclidean(u, v[, w])	Computes the Euclidean distance between two 1-D arrays.
jensenshannon(p, q[, base, axis, keepdims])	Compute the Jensen-Shannon distance (metric) between two probability arrays.
mahalanobis(u, v, VI)	Compute the Mahalanobis distance between two 1-D arrays.
minkowski(u, v[, p, w])	Compute the Minkowski distance between two 1-D arrays.
seuclidean(u, v, V)	Return the standardized Euclidean distance between two 1-D arrays.
sqeuclidean(u, v[, w])	Compute the squared Euclidean distance between two 1-D arrays.
wminkowski(u, v, p, w)	Compute the weighted Minkowski distance between two 1-D arrays.

scipy.spatial.distance.braycurtis

scipy.spatial.distance.**braycurtis**(*u*, *v*, *w=None*)

Compute the Bray-Curtis distance between two 1-D arrays.

Bray-Curtis distance is defined as

$$\sum |u_i - v_i| / \sum |u_i + v_i|$$

The Bray-Curtis distance is in the range [0, 1] if all coordinates are positive, and is undefined if the inputs are of length zero.

Parameters

u [(N,) array_like] Input array.

v [(N,) array_like] Input array.

w [(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

braycurtis [double] The Bray-Curtis distance between 1-D arrays *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.braycurtis([1, 0, 0], [0, 1, 0])
1.0
>>> distance.braycurtis([1, 1, 0], [0, 1, 0])
0.33333333333333331
```

scipy.spatial.distance.canberra

scipy.spatial.distance.**canberra**(*u*, *v*, *w=None*)

Compute the Canberra distance between two 1-D arrays.

The Canberra distance is defined as

$$d(u,v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}.$$

Parameters

u	[(N,) array_like] Input array.
v	[(N,) array_like] Input array.
w	[(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

canberra	[double] The Canberra distance between vectors *u* and *v*.

Notes

When *u[i]* and *v[i]* are 0 for given i, then the fraction 0/0 = 0 is used in the calculation.

Examples

```
>>> from scipy.spatial import distance
>>> distance.canberra([1, 0, 0], [0, 1, 0])
2.0
>>> distance.canberra([1, 1, 0], [0, 1, 0])
1.0
```

scipy.spatial.distance.chebyshev

scipy.spatial.distance.**chebyshev**(*u*, *v*, *w=None*)

Compute the Chebyshev distance.

Computes the Chebyshev distance between two 1-D arrays *u* and *v*, which is defined as

$$\max_i |u_i - v_i|.$$

Parameters

u	[(N,) array_like] Input vector.
v	[(N,) array_like] Input vector.
w	[(N,) array_like, optional] Unused, as 'max' is a weightless operation. Here for API consistency.

Returns

chebyshev	[double] The Chebyshev distance between vectors *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.chebyshev([1, 0, 0], [0, 1, 0])
1
>>> distance.chebyshev([1, 1, 0], [0, 1, 0])
1
```

scipy.spatial.distance.cityblock

scipy.spatial.distance.**cityblock**(*u*, *v*, *w=None*)

Compute the City Block (Manhattan) distance.

Computes the Manhattan distance between two 1-D arrays *u* and *v*, which is defined as

$$\sum_i |u_i - v_i|.$$

Parameters

u [(N,) array_like] Input array.

v [(N,) array_like] Input array.

w [(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

cityblock [double] The City Block (Manhattan) distance between vectors *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.cityblock([1, 0, 0], [0, 1, 0])
2
>>> distance.cityblock([1, 0, 0], [0, 2, 0])
3
>>> distance.cityblock([1, 0, 0], [1, 1, 0])
1
```

scipy.spatial.distance.correlation

scipy.spatial.distance.**correlation**(*u*, *v*, *w=None*, *centered=True*)

Compute the correlation distance between two 1-D arrays.

The correlation distance between *u* and *v*, is defined as

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{||(u - \bar{u})||_2 ||(v - \bar{v})||_2}$$

where $\bar{u}$ is the mean of the elements of *u* and $x \cdot y$ is the dot product of x and y.

Parameters

u [(N,) array_like] Input array.

v [(N,) array_like] Input array.

w [(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

centered [bool, optional] If True, *u* and *v* will be centered. Default is True.

Returns

correlation
[double] The correlation distance between 1-D array *u* and *v*.

scipy.spatial.distance.cosine

scipy.spatial.distance.**cosine**(*u*, *v*, *w=None*)
Compute the Cosine distance between 1-D arrays.

The Cosine distance between *u* and *v*, is defined as

$$1 - \frac{u \cdot v}{||u||_2||v||_2}.$$

where $u \cdot v$ is the dot product of u and v.

Parameters

u [(N,) array_like] Input array.
v [(N,) array_like] Input array.
w [(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

cosine [double] The Cosine distance between vectors *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.cosine([1, 0, 0], [0, 1, 0])
1.0
>>> distance.cosine([100, 0, 0], [0, 1, 0])
1.0
>>> distance.cosine([1, 1, 0], [0, 1, 0])
0.29289321881345254
```

scipy.spatial.distance.euclidean

scipy.spatial.distance.**euclidean**(*u*, *v*, *w=None*)
Computes the Euclidean distance between two 1-D arrays.

The Euclidean distance between 1-D arrays *u* and *v*, is defined as

$$\frac{||u - v||_2}{\left(\sum (w_i|(u_i - v_i)|^2)\right)^{1/2}}$$

Parameters

u [(N,) array_like] Input array.
v [(N,) array_like] Input array.
w [(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

euclidean [double] The Euclidean distance between vectors *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.euclidean([1, 0, 0], [0, 1, 0])
1.4142135623730951
>>> distance.euclidean([1, 1, 0], [0, 1, 0])
1.0
```

scipy.spatial.distance.jensenshannon

scipy.spatial.distance.**jensenshannon**(*p*, *q*, *base=None*, ***, *axis=0*, *keepdims=False*)

Compute the Jensen-Shannon distance (metric) between two probability arrays. This is the square root of the Jensen-Shannon divergence.

The Jensen-Shannon distance between two probability vectors p and q is defined as,

$$\sqrt{\frac{D(p \parallel m) + D(q \parallel m)}{2}}$$

where m is the pointwise mean of p and q and D is the Kullback-Leibler divergence.

This routine will normalize p and q if they don't sum to 1.0.

Parameters

p [(N,) array_like] left probability vector

q [(N,) array_like] right probability vector

base [double, optional] the base of the logarithm used to compute the output if not given, then the routine uses the default base of scipy.stats.entropy.

axis [int, optional] Axis along which the Jensen-Shannon distances are computed. The default is 0.
New in version 1.7.0.

keepdims [bool, optional] If this is set to *True*, the reduced axes are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array. Default is False.
New in version 1.7.0.

Returns

js [double or ndarray] The Jensen-Shannon distances between p and q along the *axis*.

Notes

New in version 1.2.0.

Examples

```
>>> from scipy.spatial import distance
>>> distance.jensenshannon([1.0, 0.0, 0.0], [0.0, 1.0, 0.0], 2.0)
1.0
>>> distance.jensenshannon([1.0, 0.0], [0.5, 0.5])
0.46450140402245893
>>> distance.jensenshannon([1.0, 0.0, 0.0], [1.0, 0.0, 0.0])
0.0
>>> a = np.array([[1, 2, 3, 4],
```

(continues on next page)

(continued from previous page)

```
...                [5, 6, 7, 8],
...                [9, 10, 11, 12]])
>>> b = np.array([[13, 14, 15, 16],
...                [17, 18, 19, 20],
...                [21, 22, 23, 24]])
>>> distance.jensenshannon(a, b, axis=0)
array([0.1954288, 0.1447697, 0.1138377, 0.0927636])
>>> distance.jensenshannon(a, b, axis=1)
array([0.1402339, 0.0399106, 0.0201815])
```

scipy.spatial.distance.mahalanobis

scipy.spatial.distance.**mahalanobis**(*u*, *v*, *VI*)

Compute the Mahalanobis distance between two 1-D arrays.

The Mahalanobis distance between 1-D arrays *u* and *v*, is defined as

$$\sqrt{(u-v)V^{-1}(u-v)^T}$$

where V is the covariance matrix. Note that the argument *VI* is the inverse of V.

Parameters

u	[(N,) array_like] Input array.
v	[(N,) array_like] Input array.
VI	[array_like] The inverse of the covariance matrix.

Returns

mahalanobis
: [double] The Mahalanobis distance between vectors *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> iv = [[1, 0.5, 0.5], [0.5, 1, 0.5], [0.5, 0.5, 1]]
>>> distance.mahalanobis([1, 0, 0], [0, 1, 0], iv)
1.0
>>> distance.mahalanobis([0, 2, 0], [0, 1, 0], iv)
1.0
>>> distance.mahalanobis([2, 0, 0], [0, 1, 0], iv)
1.7320508075688772
```

scipy.spatial.distance.minkowski

scipy.spatial.distance.**minkowski**(*u*, *v*, *p=2*, *w=None*)

Compute the Minkowski distance between two 1-D arrays.

The Minkowski distance between 1-D arrays *u* and *v*, is defined as

$$||u-v||_p = (\sum |u_i - v_i|^p)^{1/p}.$$
$$\left(\sum w_i(|(u_i - v_i)|^p)\right)^{1/p}.$$

Parameters

u [(N,) array_like] Input array.
v [(N,) array_like] Input array.
p [scalar] The order of the norm of the difference $||u - v||_p$.
w [(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

minkowski
[double] The Minkowski distance between vectors *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.minkowski([1, 0, 0], [0, 1, 0], 1)
2.0
>>> distance.minkowski([1, 0, 0], [0, 1, 0], 2)
1.4142135623730951
>>> distance.minkowski([1, 0, 0], [0, 1, 0], 3)
1.2599210498948732
>>> distance.minkowski([1, 1, 0], [0, 1, 0], 1)
1.0
>>> distance.minkowski([1, 1, 0], [0, 1, 0], 2)
1.0
>>> distance.minkowski([1, 1, 0], [0, 1, 0], 3)
1.0
```

scipy.spatial.distance.seuclidean

scipy.spatial.distance.**seuclidean**(*u*, *v*, *V*)
Return the standardized Euclidean distance between two 1-D arrays.

The standardized Euclidean distance between *u* and *v*.

Parameters

u [(N,) array_like] Input array.
v [(N,) array_like] Input array.
V [(N,) array_like] *V* is an 1-D array of component variances. It is usually computed among a larger collection vectors.

Returns

seuclidean [double] The standardized Euclidean distance between vectors *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.seuclidean([1, 0, 0], [0, 1, 0], [0.1, 0.1, 0.1])
4.4721359549995796
>>> distance.seuclidean([1, 0, 0], [0, 1, 0], [1, 0.1, 0.1])
3.3166247903553998
>>> distance.seuclidean([1, 0, 0], [0, 1, 0], [10, 0.1, 0.1])
3.1780497164141406
```

scipy.spatial.distance.sqeuclidean

scipy.spatial.distance.**sqeuclidean**(*u*, *v*, *w=None*)

Compute the squared Euclidean distance between two 1-D arrays.

The squared Euclidean distance between *u* and *v* is defined as

$$||u - v||_2^2$$
$$\left(\sum (w_i|(u_i - v_i)|^2)\right)$$

Parameters

u [(N,) array_like] Input array.
v [(N,) array_like] Input array.
w [(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

sqeuclidean
[double] The squared Euclidean distance between vectors *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.sqeuclidean([1, 0, 0], [0, 1, 0])
2.0
>>> distance.sqeuclidean([1, 1, 0], [0, 1, 0])
1.0
```

scipy.spatial.distance.wminkowski

scipy.spatial.distance.**wminkowski**(*u*, *v*, *p*, *w*)

Compute the weighted Minkowski distance between two 1-D arrays.

The weighted Minkowski distance between *u* and *v*, defined as

$$\left(\sum (|w_i(u_i - v_i)|^p)\right)^{1/p}.$$

Parameters

u [(N,) array_like] Input array.
v [(N,) array_like] Input array.
p [scalar] The order of the norm of the difference $||u - v||_p$.
w [(N,) array_like] The weight vector.

Returns

wminkowski
[double] The weighted Minkowski distance between vectors *u* and *v*.

Notes

wminkowski is deprecated and will be removed in SciPy 1.8.0. Use *minkowski* with the w argument instead.

Examples

```
>>> from scipy.spatial import distance
>>> distance.wminkowski([1, 0, 0], [0, 1, 0], 1, np.ones(3))
2.0
>>> distance.wminkowski([1, 0, 0], [0, 1, 0], 2, np.ones(3))
1.4142135623730951
>>> distance.wminkowski([1, 0, 0], [0, 1, 0], 3, np.ones(3))
1.2599210498948732
>>> distance.wminkowski([1, 1, 0], [0, 1, 0], 1, np.ones(3))
1.0
>>> distance.wminkowski([1, 1, 0], [0, 1, 0], 2, np.ones(3))
1.0
>>> distance.wminkowski([1, 1, 0], [0, 1, 0], 3, np.ones(3))
1.0
```

Distance functions between two boolean vectors (representing sets) u and v. As in the case of numerical vectors, pdist is more efficient for computing the distances between all pairs.

dice(u, v[, w])	Compute the Dice dissimilarity between two boolean 1-D arrays.
hamming(u, v[, w])	Compute the Hamming distance between two 1-D arrays.
jaccard(u, v[, w])	Compute the Jaccard-Needham dissimilarity between two boolean 1-D arrays.
kulsinski(u, v[, w])	Compute the Kulsinski dissimilarity between two boolean 1-D arrays.
rogerstanimoto(u, v[, w])	Compute the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.
russellrao(u, v[, w])	Compute the Russell-Rao dissimilarity between two boolean 1-D arrays.
sokalmichener(u, v[, w])	Compute the Sokal-Michener dissimilarity between two boolean 1-D arrays.
sokalsneath(u, v[, w])	Compute the Sokal-Sneath dissimilarity between two boolean 1-D arrays.
yule(u, v[, w])	Compute the Yule dissimilarity between two boolean 1-D arrays.

scipy.spatial.distance.dice

scipy.spatial.distance.**dice**(*u*, *v*, *w=None*)

Compute the Dice dissimilarity between two boolean 1-D arrays.

The Dice dissimilarity between *u* and *v*, is

$$\frac{c_{TF} + c_{FT}}{2c_{TT} + c_{FT} + c_{TF}}$$

where c_{ij} is the number of occurrences of $\mathtt{u}[\mathtt{k}] = i$ and $\mathtt{v}[\mathtt{k}] = j$ for $k < n$.

Parameters

u [(N,) array_like, bool] Input 1-D array.
v [(N,) array_like, bool] Input 1-D array.
w [(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

dice [double] The Dice dissimilarity between 1-D arrays *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.dice([1, 0, 0], [0, 1, 0])
1.0
>>> distance.dice([1, 0, 0], [1, 1, 0])
0.3333333333333333
>>> distance.dice([1, 0, 0], [2, 0, 0])
-0.3333333333333333
```

scipy.spatial.distance.hamming

scipy.spatial.distance.**hamming**(*u*, *v*, *w=None*)
Compute the Hamming distance between two 1-D arrays.

The Hamming distance between 1-D arrays *u* and *v*, is simply the proportion of disagreeing components in *u* and *v*. If *u* and *v* are boolean vectors, the Hamming distance is

$$\frac{c_{01} + c_{10}}{n}$$

where c_{ij} is the number of occurrences of $\mathtt{u}[\mathtt{k}] = i$ and $\mathtt{v}[\mathtt{k}] = j$ for $k < n$.

Parameters

u [(N,) array_like] Input array.
v [(N,) array_like] Input array.
w [(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

hamming [double] The Hamming distance between vectors *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.hamming([1, 0, 0], [0, 1, 0])
0.66666666666666663
>>> distance.hamming([1, 0, 0], [1, 1, 0])
0.33333333333333331
>>> distance.hamming([1, 0, 0], [2, 0, 0])
0.33333333333333331
>>> distance.hamming([1, 0, 0], [3, 0, 0])
0.33333333333333331
```

scipy.spatial.distance.jaccard

scipy.spatial.distance.**jaccard**(*u*, *v*, *w=None*)

Compute the Jaccard-Needham dissimilarity between two boolean 1-D arrays.

The Jaccard-Needham dissimilarity between 1-D boolean arrays *u* and *v*, is defined as

$$\frac{c_{TF} + c_{FT}}{c_{TT} + c_{FT} + c_{TF}}$$

where c_{ij} is the number of occurrences of $\mathtt{u}[\mathtt{k}] = i$ and $\mathtt{v}[\mathtt{k}] = j$ for $k < n$.

Parameters

u	[(N,) array_like, bool] Input array.
v	[(N,) array_like, bool] Input array.
w	[(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

jaccard	[double] The Jaccard distance between vectors *u* and *v*.

Notes

When both *u* and *v* lead to a *0/0* division i.e. there is no overlap between the items in the vectors the returned distance is 0. See the Wikipedia page on the Jaccard index [1], and this paper [2].

Changed in version 1.2.0: Previously, when *u* and *v* lead to a *0/0* division, the function would return NaN. This was changed to return 0 instead.

References

[1], [2]

Examples

```
>>> from scipy.spatial import distance
>>> distance.jaccard([1, 0, 0], [0, 1, 0])
1.0
>>> distance.jaccard([1, 0, 0], [1, 1, 0])
0.5
>>> distance.jaccard([1, 0, 0], [1, 2, 0])
0.5
>>> distance.jaccard([1, 0, 0], [1, 1, 1])
0.6666666666666663
```

scipy.spatial.distance.kulsinski

scipy.spatial.distance.**kulsinski**(*u*, *v*, *w=None*)

Compute the Kulsinski dissimilarity between two boolean 1-D arrays.

The Kulsinski dissimilarity between two boolean 1-D arrays *u* and *v*, is defined as

$$\frac{c_{TF} + c_{FT} - c_{TT} + n}{c_{FT} + c_{TF} + n}$$

where c_{ij} is the number of occurrences of $\mathtt{u}[\mathtt{k}] = i$ and $\mathtt{v}[\mathtt{k}] = j$ for $k < n$.

Parameters

u [(N,) array_like, bool] Input array.

v [(N,) array_like, bool] Input array.

w [(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

kulsinski [double] The Kulsinski distance between vectors *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.kulsinski([1, 0, 0], [0, 1, 0])
1.0
>>> distance.kulsinski([1, 0, 0], [1, 1, 0])
0.75
>>> distance.kulsinski([1, 0, 0], [2, 1, 0])
0.3333333333333331
>>> distance.kulsinski([1, 0, 0], [3, 1, 0])
-0.5
```

scipy.spatial.distance.rogerstanimoto

scipy.spatial.distance.**rogerstanimoto**(*u*, *v*, *w=None*)

Compute the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.

The Rogers-Tanimoto dissimilarity between two boolean 1-D arrays *u* and *v*, is defined as

$$\frac{R}{c_{TT} + c_{FF} + R}$$

where c_{ij} is the number of occurrences of $\mathtt{u}[\mathtt{k}] = i$ and $\mathtt{v}[\mathtt{k}] = j$ for $k < n$ and $R = 2(c_{TF} + c_{FT})$.

Parameters

u [(N,) array_like, bool] Input array.

v [(N,) array_like, bool] Input array.

w [(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

rogerstanimoto
[double] The Rogers-Tanimoto dissimilarity between vectors *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.rogerstanimoto([1, 0, 0], [0, 1, 0])
0.8
>>> distance.rogerstanimoto([1, 0, 0], [1, 1, 0])
0.5
>>> distance.rogerstanimoto([1, 0, 0], [2, 0, 0])
-1.0
```

scipy.spatial.distance.russellrao

scipy.spatial.distance.**russellrao**(*u*, *v*, *w=None*)

Compute the Russell-Rao dissimilarity between two boolean 1-D arrays.

The Russell-Rao dissimilarity between two boolean 1-D arrays, *u* and *v*, is defined as

$$\frac{n - c_{TT}}{n}$$

where c_{ij} is the number of occurrences of $\mathtt{u}[\mathtt{k}] = i$ and $\mathtt{v}[\mathtt{k}] = j$ for $k < n$.

Parameters

u	[(N,) array_like, bool] Input array.
v	[(N,) array_like, bool] Input array.
w	[(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

russellrao	[double] The Russell-Rao dissimilarity between vectors *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.russellrao([1, 0, 0], [0, 1, 0])
1.0
>>> distance.russellrao([1, 0, 0], [1, 1, 0])
0.6666666666666666
>>> distance.russellrao([1, 0, 0], [2, 0, 0])
0.3333333333333333
```

scipy.spatial.distance.sokalmichener

scipy.spatial.distance.**sokalmichener**(*u*, *v*, *w=None*)

Compute the Sokal-Michener dissimilarity between two boolean 1-D arrays.

The Sokal-Michener dissimilarity between boolean 1-D arrays *u* and *v*, is defined as

$$\frac{R}{S + R}$$

where c_{ij} is the number of occurrences of $\mathtt{u}[\mathtt{k}] = i$ and $\mathtt{v}[\mathtt{k}] = j$ for $k < n$, $R = 2 * (c_{TF} + c_{FT})$ and $S = c_{FF} + c_{TT}$.

Parameters

u [(N,) array_like, bool] Input array.
v [(N,) array_like, bool] Input array.
w [(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

sokalmichener
[double] The Sokal-Michener dissimilarity between vectors *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.sokalmichener([1, 0, 0], [0, 1, 0])
0.8
>>> distance.sokalmichener([1, 0, 0], [1, 1, 0])
0.5
>>> distance.sokalmichener([1, 0, 0], [2, 0, 0])
-1.0
```

scipy.spatial.distance.sokalsneath

scipy.spatial.distance.**sokalsneath**(*u*, *v*, *w=None*)
Compute the Sokal-Sneath dissimilarity between two boolean 1-D arrays.

The Sokal-Sneath dissimilarity between *u* and *v*,

$$\frac{R}{c_{TT} + R}$$

where c_{ij} is the number of occurrences of $\mathtt{u}[\mathtt{k}] = i$ and $\mathtt{v}[\mathtt{k}] = j$ for $k < n$ and $R = 2(c_{TF} + c_{FT})$.

Parameters

u [(N,) array_like, bool] Input array.
v [(N,) array_like, bool] Input array.
w [(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

sokalsneath
[double] The Sokal-Sneath dissimilarity between vectors *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.sokalsneath([1, 0, 0], [0, 1, 0])
1.0
>>> distance.sokalsneath([1, 0, 0], [1, 1, 0])
0.66666666666666663
>>> distance.sokalsneath([1, 0, 0], [2, 1, 0])
0.0
>>> distance.sokalsneath([1, 0, 0], [3, 1, 0])
-2.0
```

scipy.spatial.distance.yule

scipy.spatial.distance.**yule**(*u*, *v*, *w=None*)

Compute the Yule dissimilarity between two boolean 1-D arrays.

The Yule dissimilarity is defined as

$$\frac{R}{c_{TT} * c_{FF} + \frac{R}{2}}$$

where c_{ij} is the number of occurrences of $\mathtt{u}[\mathtt{k}] = i$ and $\mathtt{v}[\mathtt{k}] = j$ for $k < n$ and $R = 2.0 * c_{TF} * c_{FT}$.

Parameters

u	[(N,) array_like, bool] Input array.
v	[(N,) array_like, bool] Input array.
w	[(N,) array_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

Returns

yule	[double] The Yule dissimilarity between vectors *u* and *v*.

Examples

```
>>> from scipy.spatial import distance
>>> distance.yule([1, 0, 0], [0, 1, 0])
2.0
>>> distance.yule([1, 1, 0], [0, 1, 0])
0.0
```

hamming also operates over discrete numerical vectors.

3.3.28 Special functions (scipy.special)

Nearly all of the functions below are universal functions and follow broadcasting and automatic array-looping rules.

See also:

scipy.special.cython_special – Typed Cython versions of special functions

Error handling

Errors are handled by returning NaNs or other appropriate values. Some of the special function routines can emit warnings or raise exceptions when an error occurs. By default this is disabled; to query and control the current error handling state the following functions are provided.

geterr	Get the current way of handling special-function errors.
seterr	Set how special-function errors are handled.
errstate(**kwargs)	Context manager for special-function error handling.
SpecialFunctionWarning	Warning that can be emitted by special functions.
SpecialFunctionError	Exception that can be raised by special functions.

scipy.special.geterr

scipy.special.**geterr**()

Get the current way of handling special-function errors.

Returns

err : [dict] A dictionary with keys "singular", "underflow", "overflow", "slow", "loss", "no_result", "domain", "arg", and "other", whose values are from the strings "ignore", "warn", and "raise". The keys represent possible special-function errors, and the values define how these errors are handled.

See also:

seterr

set how special-function errors are handled

errstate

context manager for special-function error handling

numpy.geterr

similar numpy function for floating-point errors

Notes

For complete documentation of the types of special-function errors and treatment options, see *seterr*.

Examples

By default all errors are ignored.

```
>>> import scipy.special as sc
>>> for key, value in sorted(sc.geterr().items()):
...     print("{}: {}".format(key, value))
...
arg: ignore
domain: ignore
loss: ignore
no_result: ignore
other: ignore
overflow: ignore
singular: ignore
slow: ignore
underflow: ignore
```

scipy.special.seterr

scipy.special.**seterr**()

Set how special-function errors are handled.

Parameters

all	[{'ignore', 'warn' 'raise'}, optional] Set treatment for all type of special-function errors at once. The options are: • 'ignore' Take no action when the error occurs • 'warn' Print a *SpecialFunctionWarning* when the error occurs (via the Python warnings module) • 'raise' Raise a *SpecialFunctionError* when the error occurs. The default is to not change the current behavior. If behaviors for additional categories of special-function errors are specified, then all is applied first, followed by the additional categories.
singular	[{'ignore', 'warn', 'raise'}, optional] Treatment for singularities.
underflow	[{'ignore', 'warn', 'raise'}, optional] Treatment for underflow.
overflow	[{'ignore', 'warn', 'raise'}, optional] Treatment for overflow.
slow	[{'ignore', 'warn', 'raise'}, optional] Treatment for slow convergence.
loss	[{'ignore', 'warn', 'raise'}, optional] Treatment for loss of accuracy.
no_result	[{'ignore', 'warn', 'raise'}, optional] Treatment for failing to find a result.
domain	[{'ignore', 'warn', 'raise'}, optional] Treatment for an invalid argument to a function.
arg	[{'ignore', 'warn', 'raise'}, optional] Treatment for an invalid parameter to a function.
other	[{'ignore', 'warn', 'raise'}, optional] Treatment for an unknown error.

Returns

olderr	[dict] Dictionary containing the old settings.

See also:

geterr

get the current way of handling special-function errors

errstate

context manager for special-function error handling

numpy.seterr

similar numpy function for floating-point errors

Examples

```
>>> import scipy.special as sc
>>> from pytest import raises
>>> sc.gammaln(0)
inf
>>> olderr = sc.seterr(singular='raise')
>>> with raises(sc.SpecialFunctionError):
...     sc.gammaln(0)
...
>>> _ = sc.seterr(**olderr)
```

We can also raise for every category except one.

```
>>> olderr = sc.seterr(all='raise', singular='ignore')
>>> sc.gammaln(0)
inf
>>> with raises(sc.SpecialFunctionError):
...     sc.spence(-1)
...
>>> _ = sc.seterr(**olderr)
```

scipy.special.errstate

class scipy.special.**errstate**(***kwargs*)

Context manager for special-function error handling.

Using an instance of *errstate* as a context manager allows statements in that context to execute with a known error handling behavior. Upon entering the context the error handling is set with *seterr*, and upon exiting it is restored to what it was before.

Parameters

kwargs [{all, singular, underflow, overflow, slow, loss, no_result, domain, arg, other}] Keyword arguments. The valid keywords are possible special-function errors. Each keyword should have a string value that defines the treatement for the particular type of error. Values must be 'ignore', 'warn', or 'other'. See *seterr* for details.

See also:

geterr

get the current way of handling special-function errors

seterr

set how special-function errors are handled

numpy.errstate

similar numpy function for floating-point errors

Examples

```
>>> import scipy.special as sc
>>> from pytest import raises
>>> sc.gammaln(0)
inf
>>> with sc.errstate(singular='raise'):
...     with raises(sc.SpecialFunctionError):
...         sc.gammaln(0)
...
>>> sc.gammaln(0)
inf
```

We can also raise on every category except one.

```
>>> with sc.errstate(all='raise', singular='ignore'):
...     sc.gammaln(0)
...     with raises(sc.SpecialFunctionError):
```

(continues on next page)

(continued from previous page)

scipy.special.SpecialFunctionWarning

exception scipy.special.**SpecialFunctionWarning**
Warning that can be emitted by special functions.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

scipy.special.SpecialFunctionError

exception scipy.special.**SpecialFunctionError**
Exception that can be raised by special functions.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

Available functions

Airy functions

airy(z)	Airy functions and their derivatives.
airye(z)	Exponentially scaled Airy functions and their derivatives.
ai_zeros(nt)	Compute *nt* zeros and values of the Airy function Ai and its derivative.
bi_zeros(nt)	Compute *nt* zeros and values of the Airy function Bi and its derivative.
itairy(x)	Integrals of Airy functions

scipy.special.airy

scipy.special.**airy**(*z*) **= <ufunc 'airy'>**
Airy functions and their derivatives.

Parameters

z [array_like] Real or complex argument.

Returns

Ai, Aip, Bi, Bip
[ndarrays] Airy functions Ai and Bi, and their derivatives Aip and Bip.

See also:

airye

exponentially scaled Airy functions.

Notes

The Airy functions Ai and Bi are two independent solutions of

$$y''(x) = xy(x).$$

For real z in [-10, 10], the computation is carried out by calling the Cephes [1] *airy* routine, which uses power series summation for small z and rational minimax approximations for large z.

Outside this range, the AMOS [2] *zairy* and *zbiry* routines are employed. They are computed using power series for $|z| < 1$ and the following relations to modified Bessel functions for larger z (where $t \equiv 2z^{3/2}/3$):

$$Ai(z) = \frac{1}{\pi\sqrt{3}} K_{1/3}(t)$$

$$Ai'(z) = -\frac{z}{\pi\sqrt{3}} K_{2/3}(t)$$

$$Bi(z) = \sqrt{\frac{z}{3}} \left(I_{-1/3}(t) + I_{1/3}(t)\right)$$

$$Bi'(z) = \frac{z}{\sqrt{3}} \left(I_{-2/3}(t) + I_{2/3}(t)\right)$$

References

[1], [2]

Examples

Compute the Airy functions on the interval [-15, 5].

```
>>> from scipy import special
>>> x = np.linspace(-15, 5, 201)
>>> ai, aip, bi, bip = special.airy(x)
```

Plot Ai(x) and Bi(x).

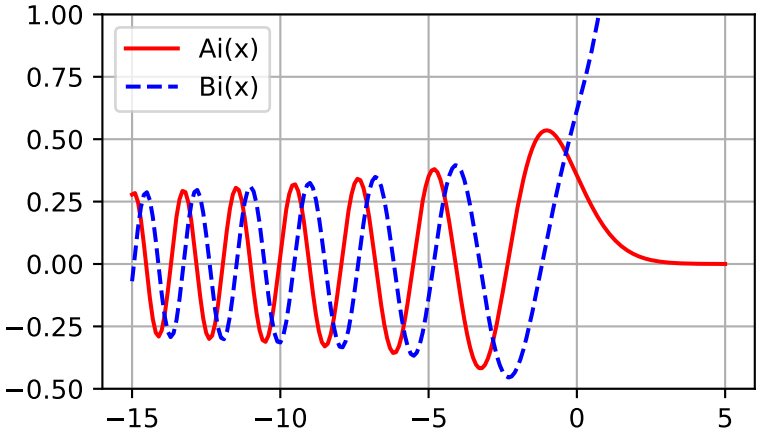
```
>>> import matplotlib.pyplot as plt
>>> plt.plot(x, ai, 'r', label='Ai(x)')
>>> plt.plot(x, bi, 'b--', label='Bi(x)')
>>> plt.ylim(-0.5, 1.0)
>>> plt.grid()
>>> plt.legend(loc='upper left')
>>> plt.show()
```

scipy.special.airye

scipy.special.**airye**(*z*) **= <ufunc 'airye'>**

Exponentially scaled Airy functions and their derivatives.

Scaling:



```
eAi  = Ai  * exp(2.0/3.0*z*sqrt(z))
eAip = Aip * exp(2.0/3.0*z*sqrt(z))
eBi  = Bi  * exp(-abs(2.0/3.0*(z*sqrt(z)).real))
eBip = Bip * exp(-abs(2.0/3.0*(z*sqrt(z)).real))
```

Parameters

z [array_like] Real or complex argument.

Returns

eAi, eAip, eBi, eBip
[array_like] Exponentially scaled Airy functions eAi and eBi, and their derivatives eAip and eBip

See also:

`airy`

Notes

Wrapper for the AMOS [1] routines *zairy* and *zbiry*.

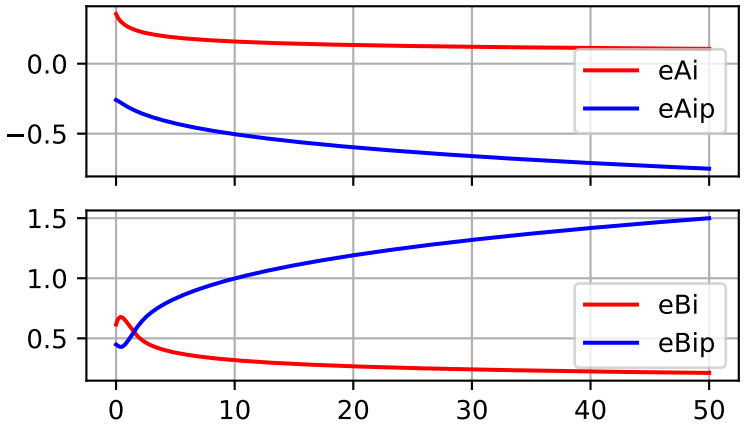
References

[1]

Examples

We can compute exponentially scaled Airy functions and their derivatives:

```
>>> from scipy.special import airye
>>> import matplotlib.pyplot as plt
>>> z = np.linspace(0, 50, 500)
>>> eAi, eAip, eBi, eBip = airye(z)
>>> f, ax = plt.subplots(2, 1, sharex=True)
>>> for ind, data in enumerate([[eAi, eAip, ["eAi", "eAip"]],
...                             [eBi, eBip, ["eBi", "eBip"]]]):
...     ax[ind].plot(z, data[0], "-r", z, data[1], "-b")
...     ax[ind].legend(data[2])
...     ax[ind].grid(True)
>>> plt.show()
```



We can compute these using usual non-scaled Airy functions by:

```
>>> from scipy.special import airy
>>> Ai, Aip, Bi, Bip = airy(z)
>>> np.allclose(eAi, Ai * np.exp(2.0 / 3.0 * z * np.sqrt(z)))
True
>>> np.allclose(eAip, Aip * np.exp(2.0 / 3.0 * z * np.sqrt(z)))
True
>>> np.allclose(eBi, Bi * np.exp(-abs(np.real(2.0 / 3.0 * z * np.
↪sqrt(z)))))
True
>>> np.allclose(eBip, Bip * np.exp(-abs(np.real(2.0 / 3.0 * z * np.
↪sqrt(z)))))
True
```

Comparing non-scaled and exponentially scaled ones, the usual non-scaled function quickly underflows for large values, whereas the exponentially scaled function does not.

```
>>> airy(200)
(0.0, 0.0, nan, nan)
>>> airye(200)
(0.07501041684381093, -1.0609012305109042, 0.15003188417418148, 2.
↪1215836725571093)
```

scipy.special.ai_zeros

scipy.special.**ai_zeros**(*nt*)

Compute *nt* zeros and values of the Airy function Ai and its derivative.

Computes the first *nt* zeros, *a*, of the Airy function Ai(x); first *nt* zeros, *ap*, of the derivative of the Airy function Ai'(x); the corresponding values Ai(a'); and the corresponding values Ai'(a).

Parameters

nt	[int] Number of zeros to compute

Returns

a	[ndarray] First *nt* zeros of Ai(x)
ap	[ndarray] First *nt* zeros of Ai'(x)
ai	[ndarray] Values of Ai(x) evaluated at first *nt* zeros of Ai'(x)
aip	[ndarray] Values of Ai'(x) evaluated at first *nt* zeros of Ai(x)

References

[1]

Examples

```
>>> from scipy import special
>>> a, ap, ai, aip = special.ai_zeros(3)
>>> a
array([-2.33810741, -4.08794944, -5.52055983])
>>> ap
array([-1.01879297, -3.24819758, -4.82009921])
>>> ai
array([ 0.53565666, -0.41901548,  0.38040647])
>>> aip
array([ 0.70121082, -0.80311137,  0.86520403])
```

scipy.special.bi_zeros

scipy.special.**bi_zeros**(*nt*)

Compute *nt* zeros and values of the Airy function Bi and its derivative.

Computes the first *nt* zeros, b, of the Airy function Bi(x); first *nt* zeros, b', of the derivative of the Airy function Bi'(x); the corresponding values Bi(b'); and the corresponding values Bi'(b).

Parameters

nt [int] Number of zeros to compute

Returns

b [ndarray] First *nt* zeros of Bi(x)
bp [ndarray] First *nt* zeros of Bi'(x)
bi [ndarray] Values of Bi(x) evaluated at first *nt* zeros of Bi'(x)
bip [ndarray] Values of Bi'(x) evaluated at first *nt* zeros of Bi(x)

References

[1]

Examples

```
>>> from scipy import special
>>> b, bp, bi, bip = special.bi_zeros(3)
>>> b
array([-1.17371322, -3.2710933 , -4.83073784])
>>> bp
array([-2.29443968, -4.07315509, -5.51239573])
>>> bi
array([-0.45494438,  0.39652284, -0.36796916])
>>> bip
array([ 0.60195789, -0.76031014,  0.83699101])
```

scipy.special.itairy

scipy.special.**itairy**(*x*) **= <ufunc 'itairy'>**

Integrals of Airy functions

Calculates the integrals of Airy functions from 0 to *x*.

Parameters

x: array_like
Upper limit of integration (float).

Returns

Apt Integral of Ai(t) from 0 to x.
Bpt Integral of Bi(t) from 0 to x.
Ant Integral of Ai(-t) from 0 to x.
Bnt Integral of Bi(-t) from 0 to x.

Notes

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

References

[1]

Elliptic functions and integrals

ellipj(u, m)	Jacobian elliptic functions
ellipk(m)	Complete elliptic integral of the first kind.
ellipkm1(p)	Complete elliptic integral of the first kind around $m = 1$
ellipkinc(phi, m)	Incomplete elliptic integral of the first kind
ellipe(m)	Complete elliptic integral of the second kind
ellipeinc(phi, m)	Incomplete elliptic integral of the second kind

scipy.special.ellipj

scipy.special.**ellipj**(*u*, *m*) **= <ufunc 'ellipj'>**

Jacobian elliptic functions

Calculates the Jacobian elliptic functions of parameter *m* between 0 and 1, and real argument *u*.

Parameters

m [array_like] Parameter.
u [array_like] Argument.

Returns

sn, cn, dn, ph
[ndarrays] The returned functions:

```
sn(u|m), cn(u|m), dn(u|m)
```

The value *ph* is such that if $u = ellipkinc(ph, m)$, then $sn(u|m) = sin(ph)$ and $cn(u|m) = cos(ph)$.

See also:

ellipk

Complete elliptic integral of the first kind

ellipkinc

Incomplete elliptic integral of the first kind

Notes

Wrapper for the Cephes [1] routine *ellpj*.

These functions are periodic, with quarter-period on the real axis equal to the complete elliptic integral *ellipk(m)*.

Relation to incomplete elliptic integral: If *u* = *ellipkinc(phi,m)*, then *sn(u|m)* = *sin(phi)*, and *cn(u|m)* = *cos(phi)*. The *phi* is called the amplitude of *u*.

Computation is by means of the arithmetic-geometric mean algorithm, except when *m* is within 1e-9 of 0 or 1. In the latter case with *m* close to 1, the approximation applies only for *phi* < *pi/2*.

References

[1]

scipy.special.ellipk

scipy.special.**ellipk**(*m*) **= <ufunc 'ellipk'>**

Complete elliptic integral of the first kind.

This function is defined as

$$K(m) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{-1/2} dt$$

Parameters

m [array_like] The parameter of the elliptic integral.

Returns

K [array_like] Value of the elliptic integral.

See also:

ellipkm1

Complete elliptic integral of the first kind around m = 1

ellipkinc

Incomplete elliptic integral of the first kind

ellipe

Complete elliptic integral of the second kind

ellipeinc

Incomplete elliptic integral of the second kind

Notes

For more precision around point m = 1, use `ellipkm1`, which this function calls.

The parameterization in terms of m follows that of section 17.2 in [1]. Other parameterizations in terms of the complementary parameter $1 - m$, modular angle $\sin^2(\alpha) = m$, or modulus $k^2 = m$ are also used, so be careful that you choose the correct parameter.

References

[1]

scipy.special.ellipkm1

scipy.special.**ellipkm1**(*p*) **= <ufunc 'ellipkm1'>**

Complete elliptic integral of the first kind around *m* = 1

This function is defined as

$$K(p) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{-1/2} dt$$

where *m = 1 - p*.

Parameters

p [array_like] Defines the parameter of the elliptic integral as *m = 1 - p*.

Returns

K [ndarray] Value of the elliptic integral.

See also:

ellipk

Complete elliptic integral of the first kind

ellipkinc

Incomplete elliptic integral of the first kind

ellipe

Complete elliptic integral of the second kind

ellipeinc

Incomplete elliptic integral of the second kind

Notes

Wrapper for the Cephes [1] routine *ellpk*.

For *p* <= *1*, computation uses the approximation,

$$K(p) \approx P(p) - \log(p)Q(p),$$

where P and Q are tenth-order polynomials. The argument *p* is used internally rather than *m* so that the logarithmic singularity at *m* = *1* will be shifted to the origin; this preserves maximum accuracy. For *p* > *1*, the identity

$$K(p) = K(1/p)/\sqrt{(}p)$$

is used.

References

[1]

scipy.special.ellipkinc

scipy.special.**ellipkinc**(*phi*, *m*) **= <ufunc 'ellipkinc'>**

Incomplete elliptic integral of the first kind

This function is defined as

$$K(\phi, m) = \int_0^{\phi} [1 - m \sin(t)^2]^{-1/2} dt$$

This function is also called *F(phi, m)*.

Parameters

phi	[array_like] amplitude of the elliptic integral
m	[array_like] parameter of the elliptic integral

Returns

K	[ndarray] Value of the elliptic integral

See also:

ellipkm1

Complete elliptic integral of the first kind, near *m* = 1

ellipk

Complete elliptic integral of the first kind

ellipe

Complete elliptic integral of the second kind

ellipeinc

Incomplete elliptic integral of the second kind

Notes

Wrapper for the Cephes [1] routine *ellik*. The computation is carried out using the arithmetic-geometric mean algorithm.

The parameterization in terms of m follows that of section 17.2 in [2]. Other parameterizations in terms of the complementary parameter $1 - m$, modular angle $\sin^2(\alpha) = m$, or modulus $k^2 = m$ are also used, so be careful that you choose the correct parameter.

References

[1], [2]

scipy.special.ellipe

scipy.special.**ellipe**(*m*) **= <ufunc 'ellipe'>**

Complete elliptic integral of the second kind

This function is defined as

$$E(m) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{1/2} dt$$

Parameters

m [array_like] Defines the parameter of the elliptic integral.

Returns

E [ndarray] Value of the elliptic integral.

See also:

ellipkm1

Complete elliptic integral of the first kind, near *m* = 1

ellipk

Complete elliptic integral of the first kind

ellipkinc

Incomplete elliptic integral of the first kind

ellipeinc

Incomplete elliptic integral of the second kind

Notes

Wrapper for the Cephes [1] routine *ellpe*.

For *m > 0* the computation uses the approximation,

$$E(m) \approx P(1 - m) - (1 - m) \log(1 - m) Q(1 - m),$$

where P and Q are tenth-order polynomials. For *m < 0*, the relation

$$E(m) = E(m/(m - 1)) \sqrt{(1 - m)}$$

is used.

The parameterization in terms of m follows that of section 17.2 in [2]. Other parameterizations in terms of the complementary parameter $1 - m$, modular angle $\sin^2(\alpha) = m$, or modulus $k^2 = m$ are also used, so be careful that you choose the correct parameter.

References

[1], [2]

Examples

This function is used in finding the circumference of an ellipse with semi-major axis *a* and semi-minor axis *b*.

```
>>> from scipy import special
```

```
>>> a = 3.5
>>> b = 2.1
>>> e_sq = 1.0 - b**2/a**2  # eccentricity squared
```

Then the circumference is found using the following:

```
>>> C = 4*a*special.ellipe(e_sq)  # circumference formula
>>> C
17.868899204378693
```

When *a* and *b* are the same (meaning eccentricity is 0), this reduces to the circumference of a circle.

```
>>> 4*a*special.ellipe(0.0)  # formula for ellipse with a = b
21.991148575128552
>>> 2*np.pi*a  # formula for circle of radius a
21.991148575128552
```

scipy.special.ellipeinc

scipy.special.**ellipeinc**(*phi*, *m*) **= <ufunc 'ellipeinc'>**

Incomplete elliptic integral of the second kind

This function is defined as

$$E(\phi, m) = \int_0^{\phi} [1 - m \sin(t)^2]^{1/2} dt$$

Parameters

phi	[array_like] amplitude of the elliptic integral.
m	[array_like] parameter of the elliptic integral.

Returns

E	[ndarray] Value of the elliptic integral.

See also:

ellipkm1

Complete elliptic integral of the first kind, near $m = 1$

ellipk

Complete elliptic integral of the first kind

ellipkinc

Incomplete elliptic integral of the first kind

ellipe

Complete elliptic integral of the second kind

Notes

Wrapper for the Cephes [1] routine *ellie*.

Computation uses arithmetic-geometric means algorithm.

The parameterization in terms of m follows that of section 17.2 in [2]. Other parameterizations in terms of the complementary parameter $1 - m$, modular angle $\sin^2(\alpha) = m$, or modulus $k^2 = m$ are also used, so be careful that you choose the correct parameter.

References

[1], [2]

Bessel functions

jv(v, z)	Bessel function of the first kind of real order and complex argument.
jve(v, z)	Exponentially scaled Bessel function of order *v*.
yn(n, x)	Bessel function of the second kind of integer order and real argument.
yv(v, z)	Bessel function of the second kind of real order and complex argument.
yve(v, z)	Exponentially scaled Bessel function of the second kind of real order.
kn(n, x)	Modified Bessel function of the second kind of integer order *n*
kv(v, z)	Modified Bessel function of the second kind of real order *v*
kve(v, z)	Exponentially scaled modified Bessel function of the second kind.
iv(v, z)	Modified Bessel function of the first kind of real order.
ive(v, z)	Exponentially scaled modified Bessel function of the first kind
hankel1(v, z)	Hankel function of the first kind
hankel1e(v, z)	Exponentially scaled Hankel function of the first kind
hankel2(v, z)	Hankel function of the second kind
hankel2e(v, z)	Exponentially scaled Hankel function of the second kind
wright_bessel(a, b, x)	Wright's generalized Bessel function.

scipy.special.jv

scipy.special.**jv**(*v*, *z*) **= <ufunc 'jv'>**

Bessel function of the first kind of real order and complex argument.

Parameters

v	[array_like] Order (float).
z	[array_like] Argument (float or complex).

Returns

J	[ndarray] Value of the Bessel function, $J_v(z)$.

See also:

jve

J_v with leading exponential behavior stripped off.

spherical_jn

spherical Bessel functions.

Notes

For positive *v* values, the computation is carried out using the AMOS [1] *zbesj* routine, which exploits the connection to the modified Bessel function I_v,

$$J_v(z) = \exp(v\pi\imath/2) I_v(-\imath z) \qquad (\Im z > 0)$$
$$J_v(z) = \exp(-v\pi\imath/2) I_v(\imath z) \qquad (\Im z < 0)$$

For negative *v* values the formula,

$$J_{-v}(z) = J_v(z)\cos(\pi v) - Y_v(z)\sin(\pi v)$$

is used, where $Y_v(z)$ is the Bessel function of the second kind, computed using the AMOS routine *zbesy*. Note that the second term is exactly zero for integer *v*; to improve accuracy the second term is explicitly omitted for *v* values such that *v = floor(v)*.

Not to be confused with the spherical Bessel functions (see *spherical_jn*).

References

[1]

scipy.special.jve

scipy.special.**jve**(*v*, *z*) **= <ufunc 'jve'>**

Exponentially scaled Bessel function of order *v*.

Defined as:

```
jve(v, z) = jv(v, z) * exp(-abs(z.imag))
```

Parameters

v [array_like] Order (float).
z [array_like] Argument (float or complex).

Returns

J [ndarray] Value of the exponentially scaled Bessel function.

Notes

For positive *v* values, the computation is carried out using the AMOS [1] *zbesj* routine, which exploits the connection to the modified Bessel function I_v,

$$J_v(z) = \exp(v\pi\imath/2) I_v(-\imath z) \qquad (\Im z > 0)$$
$$J_v(z) = \exp(-v\pi\imath/2) I_v(\imath z) \qquad (\Im z < 0)$$

For negative *v* values the formula,

$$J_{-v}(z) = J_v(z)\cos(\pi v) - Y_v(z)\sin(\pi v)$$

is used, where $Y_v(z)$ is the Bessel function of the second kind, computed using the AMOS routine *zbesy*. Note that the second term is exactly zero for integer *v*; to improve accuracy the second term is explicitly omitted for *v* values such that *v = floor(v)*.

References

[1]

scipy.special.yn

`scipy.special.`**`yn`**`(n, x) = <ufunc 'yn'>`

Bessel function of the second kind of integer order and real argument.

Parameters

n [array_like] Order (integer).
z [array_like] Argument (float).

Returns

Y [ndarray] Value of the Bessel function, $Y_n(x)$.

See also:

`yv`

For real order and real or complex argument.

Notes

Wrapper for the Cephes [1] routine *yn*.

The function is evaluated by forward recurrence on *n*, starting with values computed by the Cephes routines *y0* and *y1*. If *n* = *0* or 1, the routine for *y0* or *y1* is called directly.

References

[1]

scipy.special.yv

scipy.special.**yv**(*v*, *z*) **= <ufunc 'yv'>**

Bessel function of the second kind of real order and complex argument.

Parameters

v	[array_like] Order (float).
z	[array_like] Argument (float or complex).

Returns

Y	[ndarray] Value of the Bessel function of the second kind, $Y_v(x)$.

See also:

yve

Y_v with leading exponential behavior stripped off.

Notes

For positive *v* values, the computation is carried out using the AMOS [1] *zbesy* routine, which exploits the connection to the Hankel Bessel functions $H_v^{(1)}$ and $H_v^{(2)}$,

$$Y_v(z) = \frac{1}{2\imath}(H_v^{(1)} - H_v^{(2)}).$$

For negative *v* values the formula,

$$Y_{-v}(z) = Y_v(z)\cos(\pi v) + J_v(z)\sin(\pi v)$$

is used, where $J_v(z)$ is the Bessel function of the first kind, computed using the AMOS routine *zbesj*. Note that the second term is exactly zero for integer *v*; to improve accuracy the second term is explicitly omitted for *v* values such that *v* = *floor(v)*.

References

[1]

scipy.special.yve

scipy.special.**yve**(*v*, *z*) **= <ufunc 'yve'>**

Exponentially scaled Bessel function of the second kind of real order.

Returns the exponentially scaled Bessel function of the second kind of real order *v* at complex *z*:

```
yve(v, z) = yv(v, z) * exp(-abs(z.imag))
```

Parameters

v	[array_like] Order (float).
z	[array_like] Argument (float or complex).

Returns

Y	[ndarray] Value of the exponentially scaled Bessel function.

Notes

For positive *v* values, the computation is carried out using the AMOS [1] *zbesy* routine, which exploits the connection to the Hankel Bessel functions $H_v^{(1)}$ and $H_v^{(2)}$,

$$Y_v(z) = \frac{1}{2\imath}(H_v^{(1)} - H_v^{(2)}).$$

For negative *v* values the formula,

$$Y_{-v}(z) = Y_v(z)\cos(\pi v) + J_v(z)\sin(\pi v)$$

is used, where $J_v(z)$ is the Bessel function of the first kind, computed using the AMOS routine *zbesj*. Note that the second term is exactly zero for integer *v*; to improve accuracy the second term is explicitly omitted for *v* values such that *v = floor(v)*.

References

[1]

scipy.special.kn

scipy.special.**kn**(*n*, *x*) **= <ufunc 'kn'>**

Modified Bessel function of the second kind of integer order *n*

Returns the modified Bessel function of the second kind for integer order *n* at real *z*.

These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions.

Parameters

n	[array_like of int] Order of Bessel functions (floats will truncate with a warning)
z	[array_like of float] Argument at which to evaluate the Bessel functions

Returns

out [ndarray] The results

See also:

kv

Same function, but accepts real order and complex argument

kvp

Derivative of this function

Notes

Wrapper for AMOS [1] routine *zbesk*. For a discussion of the algorithm used, see [2] and the references therein.

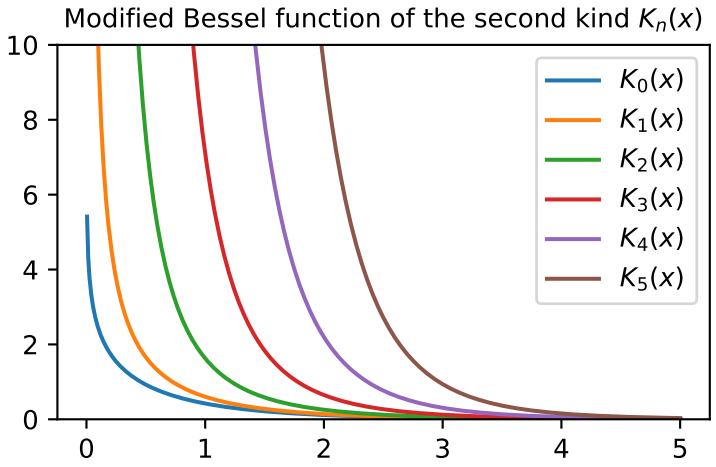
References

[1], [2]

Examples

Plot the function of several orders for real input:

```
>>> from scipy.special import kn
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in range(6):
...     plt.plot(x, kn(N, x), label='$K_{}(x)$'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_n(x)$')
>>> plt.show()
```



Calculate for a single value at multiple orders:

```
>>> kn([4, 5, 6], 1)
array([   44.23241585,   360.9605896 ,  3653.83831186])
```

scipy.special.kv

scipy.special.**kv**(*v*, *z*) **= <ufunc 'kv'>**

Modified Bessel function of the second kind of real order *v*

Returns the modified Bessel function of the second kind for real order *v* at complex *z*.

These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions. They are defined as those solutions of the modified Bessel equation for which,

$$K_v(x) \sim \sqrt{\pi/(2x)}\exp(-x)$$

as $x \to \infty$ [3].

Parameters

v	[array_like of float] Order of Bessel functions
z	[array_like of complex] Argument at which to evaluate the Bessel functions

Returns

out	[ndarray] The results. Note that input must be of complex type to get complex output, e.g. `kv(3, -2+0j)` instead of `kv(3, -2)`.

See also:

kve

This function with leading exponential behavior stripped off.

kvp

Derivative of this function

Notes

Wrapper for AMOS [1] routine *zbesk*. For a discussion of the algorithm used, see [2] and the references therein.

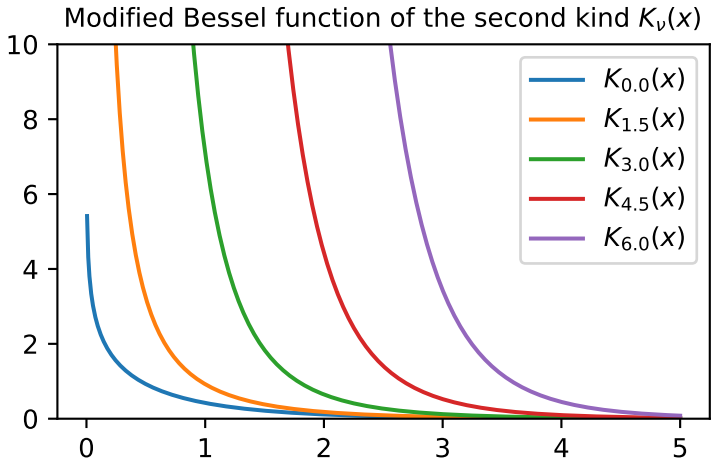
References

[1], [2], [3]

Examples

Plot the function of several orders for real input:

```
>>> from scipy.special import kv
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in np.linspace(0, 6, 5):
...     plt.plot(x, kv(N, x), label='$K_{{{}}}(x)$'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_\nu(x)$')
>>> plt.show()
```



Calculate for a single value at multiple orders:

```
>>> kv([4, 4.5, 5], 1+2j)
array([ 0.1992+2.3892j,  2.3493+3.6j    ,  7.2827+3.8104j])
```

scipy.special.kve

scipy.special.**kve**(*v*, *z*) **= <ufunc 'kve'>**

Exponentially scaled modified Bessel function of the second kind.

Returns the exponentially scaled, modified Bessel function of the second kind (sometimes called the third kind) for real order *v* at complex *z*:

```
kve(v, z) = kv(v, z) * exp(z)
```

Parameters

v	[array_like of float] Order of Bessel functions
z	[array_like of complex] Argument at which to evaluate the Bessel functions

Returns

out [ndarray] The exponentially scaled modified Bessel function of the second kind.

Notes

Wrapper for AMOS [1] routine *zbesk*. For a discussion of the algorithm used, see [2] and the references therein.

References

[1], [2]

scipy.special.iv

scipy.special.**iv**(*v*, *z*) **= <ufunc 'iv'>**

Modified Bessel function of the first kind of real order.

Parameters

v [array_like] Order. If *z* is of real type and negative, *v* must be integer valued.
z [array_like of float or complex] Argument.

Returns

out [ndarray] Values of the modified Bessel function.

See also:

kve

This function with leading exponential behavior stripped off.

Notes

For real z and $v \in [-50, 50]$, the evaluation is carried out using Temme's method [1]. For larger orders, uniform asymptotic expansions are applied.

For complex *z* and positive *v*, the AMOS [2] *zbesi* routine is called. It uses a power series for small *z*, the asymptotic expansion for large *abs(z)*, the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for $I_v(z)$ and $J_v(z)$ for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

$$I_v(z \exp(\pm \imath\pi)) = \exp(\pm \pi v) I_v(z)$$

(valid when the real part of *z* is positive). For negative *v*, the formula

$$I_{-v}(z) = I_v(z) + \frac{2}{\pi} \sin(\pi v) K_v(z)$$

is used, where $K_v(z)$ is the modified Bessel function of the second kind, evaluated using the AMOS routine *zbesk*.

References

[1], [2]

scipy.special.ive

scipy.special.**ive**(*v*, *z*) **= <ufunc 'ive'>**
Exponentially scaled modified Bessel function of the first kind

Defined as:

```
ive(v, z) = iv(v, z) * exp(-abs(z.real))
```

Parameters

v [array_like of float] Order.
z [array_like of float or complex] Argument.

Returns

out [ndarray] Values of the exponentially scaled modified Bessel function.

Notes

For positive *v*, the AMOS [1] *zbesi* routine is called. It uses a power series for small *z*, the asymptotic expansion for large *abs(z)*, the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for $I_v(z)$ and $J_v(z)$ for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

$$I_v(z \exp(\pm \imath\pi)) = \exp(\pm \pi v) I_v(z)$$

(valid when the real part of z is positive). For negative *v*, the formula

$$I_{-v}(z) = I_v(z) + \frac{2}{\pi} \sin(\pi v) K_v(z)$$

is used, where $K_v(z)$ is the modified Bessel function of the second kind, evaluated using the AMOS routine *zbesk*.

scipy.special.hankel1

scipy.special.**hankel1**(*v*, *z*) **= <ufunc 'hankel1'>**
Hankel function of the first kind

Parameters

v [array_like] Order (float).
z [array_like] Argument (float or complex).

Returns

out [Values of the Hankel function of the first kind.]

See also:

hankel1e

this function with leading exponential behavior stripped off.

Notes

A wrapper for the AMOS [1] routine *zbesh*, which carries out the computation using the relation,

$$H_v^{(1)}(z) = \frac{2}{\imath\pi}\exp(-\imath\pi v/2)K_v(z\exp(-\imath\pi/2))$$

where K_v is the modified Bessel function of the second kind. For negative orders, the relation

$$H_{-v}^{(1)}(z) = H_v^{(1)}(z)\exp(\imath\pi v)$$

is used.

References

[1]

scipy.special.hankel1e

scipy.special.**hankel1e**(*v*, *z*) **= <ufunc 'hankel1e'>**

Exponentially scaled Hankel function of the first kind

Defined as:

```
hankel1e(v, z) = hankel1(v, z) * exp(-1j * z)
```

Parameters

v [array_like] Order (float).
z [array_like] Argument (float or complex).

Returns

out [Values of the exponentially scaled Hankel function.]

Notes

A wrapper for the AMOS [1] routine *zbesh*, which carries out the computation using the relation,

$$H_v^{(1)}(z) = \frac{2}{\imath\pi}\exp(-\imath\pi v/2)K_v(z\exp(-\imath\pi/2))$$

where K_v is the modified Bessel function of the second kind. For negative orders, the relation

$$H_{-v}^{(1)}(z) = H_v^{(1)}(z)\exp(\imath\pi v)$$

is used.

References

[1]

scipy.special.hankel2

scipy.special.**hankel2**(*v*, *z*) **= <ufunc 'hankel2'>**

Hankel function of the second kind

Parameters

v	[array_like] Order (float).
z	[array_like] Argument (float or complex).

Returns

out	[Values of the Hankel function of the second kind.]

See also:

hankel2e

this function with leading exponential behavior stripped off.

Notes

A wrapper for the AMOS [1] routine *zbesh*, which carries out the computation using the relation,

$$H_v^{(2)}(z) = -\frac{2}{\imath\pi}\exp(\imath\pi v/2)K_v(z\exp(\imath\pi/2))$$

where K_v is the modified Bessel function of the second kind. For negative orders, the relation

$$H_{-v}^{(2)}(z) = H_v^{(2)}(z)\exp(-\imath\pi v)$$

is used.

References

[1]

scipy.special.hankel2e

scipy.special.**hankel2e**(*v*, *z*) **= <ufunc 'hankel2e'>**

Exponentially scaled Hankel function of the second kind

Defined as:

```
hankel2e(v, z) = hankel2(v, z) * exp(1j * z)
```

Parameters

v	[array_like] Order (float).
z	[array_like] Argument (float or complex).

Returns

out	[Values of the exponentially scaled Hankel function of the second kind.]

Notes

A wrapper for the AMOS [1] routine *zbesh*, which carries out the computation using the relation,

$$H_v^{(2)}(z) = -\frac{2}{\imath\pi}\exp(\frac{\imath\pi v}{2})K_v(zexp(\frac{\imath\pi}{2}))$$

where K_v is the modified Bessel function of the second kind. For negative orders, the relation

$$H_{-v}^{(2)}(z) = H_v^{(2)}(z)\exp(-\imath\pi v)$$

is used.

References

[1]

scipy.special.wright_bessel

scipy.special.**wright_bessel**(a, b, x) **= <ufunc 'wright_bessel'>**

Wright's generalized Bessel function.

Wright's generalized Bessel function is an entire function and defined as

$$\Phi(a, b; x) = \sum_{k=0}^{\infty} \frac{x^k}{k!\Gamma(ak+b)}$$

See also [1].

Parameters

a	[array_like of float] a >= 0
b	[array_like of float] b >= 0
x	[array_like of float] x >= 0

Notes

Due to the compexity of the function with its three parameters, only non-negative arguments are implemented.

References

[1]

Examples

```
>>> from scipy.special import wright_bessel
>>> a, b, x = 1.5, 1.1, 2.5
>>> wright_bessel(a, b-1, x)
4.5314465939443025
```

Now, let us verify the relation

$$\Phi(a, b-1; x) = ax\Phi(a, b+a; x) + (b-1)\Phi(a, b; x)$$

```
>>> a * x * wright_bessel(a, b+a, x) + (b-1) * wright_bessel(a, b, x)
4.5314465939443025
```

The following is not a universal function:

lmbda(v, x)	Jahnke-Emden Lambda function, Lambdav(x).

scipy.special.lmbda

scipy.special.**lmbda**(*v*, *x*)

Jahnke-Emden Lambda function, Lambdav(x).

This function is defined as [2],

$$\Lambda_v(x) = \Gamma(v+1)\frac{J_v(x)}{(x/2)^v},$$

where Γ is the gamma function and J_v is the Bessel function of the first kind.

Parameters

v	[float] Order of the Lambda function
x	[float] Value at which to evaluate the function and derivatives

Returns

vl	[ndarray] Values of Lambda_vi(x), for vi=v-int(v), vi=1+v-int(v), …, vi=v.
dl	[ndarray] Derivatives Lambda_vi'(x), for vi=v-int(v), vi=1+v-int(v), …, vi=v.

Zeros of Bessel functions

These are not universal functions:

jnjnp_zeros(nt)	Compute zeros of integer-order Bessel functions Jn and Jn'.
jnyn_zeros(n, nt)	Compute nt zeros of Bessel functions Jn(x), Jn'(x), Yn(x), and Yn'(x).
jn_zeros(n, nt)	Compute zeros of integer-order Bessel functions Jn.
jnp_zeros(n, nt)	Compute zeros of integer-order Bessel function derivatives Jn'.
yn_zeros(n, nt)	Compute zeros of integer-order Bessel function Yn(x).
ynp_zeros(n, nt)	Compute zeros of integer-order Bessel function derivatives Yn'(x).

continues on next page

Table 224 – continued from previous page

y0_zeros(nt[, complex])	Compute nt zeros of Bessel function Y0(z), and derivative at each zero.
y1_zeros(nt[, complex])	Compute nt zeros of Bessel function Y1(z), and derivative at each zero.
y1p_zeros(nt[, complex])	Compute nt zeros of Bessel derivative Y1'(z), and value at each zero.

scipy.special.jnjnp_zeros

scipy.special.**jnjnp_zeros**(*nt*)

Compute zeros of integer-order Bessel functions Jn and Jn'.

Results are arranged in order of the magnitudes of the zeros.

Parameters

nt [int] Number (<=1200) of zeros to compute

Returns

zo[l-1] [ndarray] Value of the lth zero of Jn(x) and Jn'(x). Of length *nt*.
n[l-1] [ndarray] Order of the Jn(x) or Jn'(x) associated with lth zero. Of length *nt*.
m[l-1] [ndarray] Serial number of the zeros of Jn(x) or Jn'(x) associated with lth zero. Of length *nt*.
t[l-1] [ndarray] 0 if lth zero in zo is zero of Jn(x), 1 if it is a zero of Jn'(x). Of length *nt*.

See also:

jn_zeros, **jnp_zeros**

to get separated arrays of zeros.

References

[1]

scipy.special.jnyn_zeros

scipy.special.**jnyn_zeros**(*n*, *nt*)

Compute nt zeros of Bessel functions Jn(x), Jn'(x), Yn(x), and Yn'(x).

Returns 4 arrays of length *nt*, corresponding to the first *nt* zeros of Jn(x), Jn'(x), Yn(x), and Yn'(x), respectively. The zeros are returned in ascending order.

Parameters

n [int] Order of the Bessel functions
nt [int] Number (<=1200) of zeros to compute

Returns

Jn [ndarray] First *nt* zeros of Jn
Jnp [ndarray] First *nt* zeros of Jn'
Yn [ndarray] First *nt* zeros of Yn
Ynp [ndarray] First *nt* zeros of Yn'

See also:

jn_zeros, **jnp_zeros**, **yn_zeros**, **ynp_zeros**

References

[1]

scipy.special.jn_zeros

scipy.special.**jn_zeros**(*n*, *nt*)

Compute zeros of integer-order Bessel functions Jn.

Compute *nt* zeros of the Bessel functions $J_n(x)$ on the interval $(0, \infty)$. The zeros are returned in ascending order. Note that this interval excludes the zero at $x = 0$ that exists for $n > 0$.

Parameters

n	[int] Order of Bessel function
nt	[int] Number of zeros to return

Returns

ndarray	First *n* zeros of the Bessel function.

See also:

jv

[1]

Examples

```
>>> import scipy.special as sc
```

We can check that we are getting approximations of the zeros by evaluating them with *jv*.

```
>>> n = 1
>>> x = sc.jn_zeros(n, 3)
>>> x
array([ 3.83170597,  7.01558667, 10.17346814])
>>> sc.jv(n, x)
array([-0.00000000e+00,  1.72975330e-16,  2.89157291e-16])
```

Note that the zero at `x = 0` for `n > 0` is not included.

```
>>> sc.jv(1, 0)
0.0
```

scipy.special.jnp_zeros

scipy.special.**jnp_zeros**(*n*, *nt*)

Compute zeros of integer-order Bessel function derivatives Jn'.

Compute *nt* zeros of the functions $J_n'(x)$ on the interval $(0, \infty)$. The zeros are returned in ascending order. Note that this interval excludes the zero at $x = 0$ that exists for $n > 1$.

Parameters

n	[int] Order of Bessel function
nt	[int] Number of zeros to return

Returns

ndarray	First *n* zeros of the Bessel function.

See also:

jvp, **jv**

Examples

```
>>> import scipy.special as sc
```

We can check that we are getting approximations of the zeros by evaluating them with *jvp*.

```
>>> n = 2
>>> x = sc.jnp_zeros(n, 3)
>>> x
array([3.05423693, 6.70613319, 9.96946782])
>>> sc.jvp(n, x)
array([ 2.77555756e-17,  2.08166817e-16, -3.01841885e-16])
```

Note that the zero at `x = 0` for `n > 1` is not included.

```
>>> sc.jvp(n, 0)
0.0
```

scipy.special.yn_zeros

scipy.special.**yn_zeros**(*n*, *nt*)

Compute zeros of integer-order Bessel function Yn(x).

Compute *nt* zeros of the functions $Y_n(x)$ on the interval $(0, \infty)$. The zeros are returned in ascending order.

Parameters

n	[int] Order of Bessel function
nt	[int] Number of zeros to return

Returns

ndarray First *n* zeros of the Bessel function.

See also:

yn, **yv**

[1]

Examples

```
>>> import scipy.special as sc
```

We can check that we are getting approximations of the zeros by evaluating them with *yn*.

```
>>> n = 2
>>> x = sc.yn_zeros(n, 3)
>>> x
array([ 3.38424177,  6.79380751, 10.02347798])
>>> sc.yn(n, x)
array([-1.94289029e-16,  8.32667268e-17, -1.52655666e-16])
```

scipy.special.ynp_zeros

scipy.special.**ynp_zeros**(*n*, *nt*)

Compute zeros of integer-order Bessel function derivatives Yn'(x).

Compute *nt* zeros of the functions $Y_n'(x)$ on the interval $(0, \infty)$. The zeros are returned in ascending order.

Parameters

n [int] Order of Bessel function
nt [int] Number of zeros to return

See also:

yvp

References

[1]

Examples

```
>>> import scipy.special as sc
```

We can check that we are getting approximations of the zeros by evaluating them with *yvp*.

```
>>> n = 2
>>> x = sc.ynp_zeros(n, 3)
>>> x
array([ 5.00258293,  8.3507247 , 11.57419547])
>>> sc.yvp(n, x)
array([ 2.22044605e-16, -3.33066907e-16,  2.94902991e-16])
```

scipy.special.y0_zeros

scipy.special.**y0_zeros**(*nt*, *complex=False*)

Compute nt zeros of Bessel function Y0(z), and derivative at each zero.

The derivatives are given by Y0'(z0) = -Y1(z0) at each zero z0.

Parameters

nt	[int] Number of zeros to return
complex	[bool, default False] Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

Returns

z0n	[ndarray] Location of nth zero of Y0(z)
y0pz0n	[ndarray] Value of derivative Y0'(z0) for nth zero

References

[1]

scipy.special.y1_zeros

scipy.special.**y1_zeros**(*nt*, *complex=False*)

Compute nt zeros of Bessel function Y1(z), and derivative at each zero.

The derivatives are given by Y1'(z1) = Y0(z1) at each zero z1.

Parameters

nt	[int] Number of zeros to return
complex	[bool, default False] Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

Returns

z1n	[ndarray] Location of nth zero of Y1(z)
y1pz1n	[ndarray] Value of derivative Y1'(z1) for nth zero

References

[1]

scipy.special.y1p_zeros

scipy.special.**y1p_zeros**(*nt*, *complex=False*)

Compute nt zeros of Bessel derivative Y1'(z), and value at each zero.

The values are given by Y1(z1) at each z1 where Y1'(z1)=0.

Parameters

nt [int] Number of zeros to return

complex [bool, default False] Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

Returns

z1pn [ndarray] Location of nth zero of Y1'(z)

y1z1pn [ndarray] Value of derivative Y1(z1) for nth zero

References

[1]

Faster versions of common Bessel functions

j0(x)	Bessel function of the first kind of order 0.
j1(x)	Bessel function of the first kind of order 1.
y0(x)	Bessel function of the second kind of order 0.
y1(x)	Bessel function of the second kind of order 1.
i0(x)	Modified Bessel function of order 0.
i0e(x)	Exponentially scaled modified Bessel function of order 0.
i1(x)	Modified Bessel function of order 1.
i1e(x)	Exponentially scaled modified Bessel function of order 1.
k0(x)	Modified Bessel function of the second kind of order 0, K_0.
k0e(x)	Exponentially scaled modified Bessel function K of order 0
k1(x)	Modified Bessel function of the second kind of order 1, $K_1(x)$.
k1e(x)	Exponentially scaled modified Bessel function K of order 1

scipy.special.j0

scipy.special.**j0**(*x*) **= <ufunc 'j0'>**

Bessel function of the first kind of order 0.

Parameters

x [array_like] Argument (float).

Returns

J [ndarray] Value of the Bessel function of the first kind of order 0 at *x*.

See also:

jv

Bessel function of real order and complex argument.

spherical_jn

spherical Bessel functions.

Notes

The domain is divided into the intervals [0, 5] and (5, infinity). In the first interval the following rational approximation is used:

$$J_0(x) \approx (w - r_1^2)(w - r_2^2)\frac{P_3(w)}{Q_8(w)},$$

where $w = x^2$ and r_1, r_2 are the zeros of J_0, and P_3 and Q_8 are polynomials of degrees 3 and 8, respectively.

In the second interval, the Hankel asymptotic expansion is employed with two rational functions of degree 6/6 and 7/7.

This function is a wrapper for the Cephes [1] routine *j0*. It should not be confused with the spherical Bessel functions (see *spherical_jn*).

References

[1]

scipy.special.j1

scipy.special.**j1**(*x*) **= <ufunc 'j1'>**

Bessel function of the first kind of order 1.

Parameters

x [array_like] Argument (float).

Returns

J [ndarray] Value of the Bessel function of the first kind of order 1 at *x*.

See also:

jv

spherical_jn

spherical Bessel functions.

Notes

The domain is divided into the intervals [0, 8] and (8, infinity). In the first interval a 24 term Chebyshev expansion is used. In the second, the asymptotic trigonometric representation is employed using two rational functions of degree 5/5.

This function is a wrapper for the Cephes [1] routine *j1*. It should not be confused with the spherical Bessel functions (see *spherical_jn*).

References

[1]

scipy.special.y0

scipy.special.**y0**(*x*) **= <ufunc 'y0'>**

Bessel function of the second kind of order 0.

Parameters

x [array_like] Argument (float).

Returns

Y [ndarray] Value of the Bessel function of the second kind of order 0 at *x*.

See also:

j0

yv

Notes

The domain is divided into the intervals [0, 5] and (5, infinity). In the first interval a rational approximation $R(x)$ is employed to compute,

$$Y_0(x) = R(x) + \frac{2\log(x)J_0(x)}{\pi},$$

where J_0 is the Bessel function of the first kind of order 0.

In the second interval, the Hankel asymptotic expansion is employed with two rational functions of degree 6/6 and 7/7.

This function is a wrapper for the Cephes [1] routine *y0*.

References

[1]

scipy.special.y1

scipy.special.**y1**(*x*) **= <ufunc 'y1'>**

Bessel function of the second kind of order 1.

Parameters

x [array_like] Argument (float).

Returns

Y [ndarray] Value of the Bessel function of the second kind of order 1 at *x*.

See also:

j1

yn

yv

Notes

The domain is divided into the intervals [0, 8] and (8, infinity). In the first interval a 25 term Chebyshev expansion is used, and computing J_1 (the Bessel function of the first kind) is required. In the second, the asymptotic trigonometric representation is employed using two rational functions of degree 5/5.

This function is a wrapper for the Cephes [1] routine *y1*.

References

[1]

scipy.special.i0

scipy.special.**i0**(*x*) **= <ufunc 'i0'>**

Modified Bessel function of order 0.

Defined as,

$$I_0(x) = \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{(k!)^2} = J_0(\imath x),$$

where J_0 is the Bessel function of the first kind of order 0.

Parameters

x [array_like] Argument (float)

Returns

I [ndarray] Value of the modified Bessel function of order 0 at *x*.

See also:

iv

i0e

Notes

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine *i0*.

References

[1]

scipy.special.i0e

scipy.special.**i0e**(*x*) **= <ufunc 'i0e'>**

Exponentially scaled modified Bessel function of order 0.

Defined as:

```
i0e(x) = exp(-abs(x)) * i0(x).
```

Parameters

x [array_like] Argument (float)

Returns

I [ndarray] Value of the exponentially scaled modified Bessel function of order 0 at *x*.

See also:

iv

i0

Notes

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in *i0*, but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephes [1] routine *i0e*.

References

[1]

scipy.special.i1

scipy.special.**i1**(*x*) **= <ufunc 'i1'>**

Modified Bessel function of order 1.

Defined as,

$$I_1(x) = \frac{1}{2}x\sum_{k=0}^{\infty}\frac{(x^2/4)^k}{k!(k+1)!} = -\imath J_1(\imath x),$$

where J_1 is the Bessel function of the first kind of order 1.

Parameters

x [array_like] Argument (float)

Returns

I [ndarray] Value of the modified Bessel function of order 1 at *x*.

See also:

iv

i1e

Notes

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine *i1*.

References

kv

k1e

Notes

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine *k1*.

References

[1]

scipy.special.k1e

scipy.special.**k1e**(*x*) **= <ufunc 'k1e'>**

Exponentially scaled modified Bessel function K of order 1

Defined as:

```
k1e(x) = exp(x) * k1(x)
```

Parameters

x [array_like] Argument (float)

Returns

K [ndarray] Value of the exponentially scaled modified Bessel function K of order 1 at *x*.

See also:

kv

k1

Notes

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine *k1e*.

Integrals of Bessel functions

itj0y0(x[, out])	Integrals of Bessel functions of the first kind of order 0.
it2j0y0(x[, out])	Integrals related to Bessel functions of the first kind of order 0.
iti0k0(x[, out])	Integrals of modified Bessel functions of order 0.
it2i0k0(x[, out])	Integrals related to modified Bessel functions of order 0.
besselpoly(a, lmb, nu[, out])	Weighted integral of the Bessel function of the first kind.

scipy.special.itj0y0

scipy.special.**itj0y0**(*x*, *out=None*) **= <ufunc 'itj0y0'>**

Integrals of Bessel functions of the first kind of order 0.

Computes the integrals

$$\int_0^x J_0(t)dt$$
$$\int_0^x Y_0(t)dt.$$

For more on J_0 and Y_0 see j0 and y0.

Parameters

x [array_like] Values at which to evaluate the integrals.
out [tuple of ndarrays, optional] Optional output arrays for the function results.

Returns

ij0 [scalar or ndarray] The integral of j0
iy0 [scalar or ndarray] The integral of y0

scipy.special.it2j0y0

scipy.special.**it2j0y0**(*x*, *out=None*) **= <ufunc 'it2j0y0'>**

Integrals related to Bessel functions of the first kind of order 0.

Computes the integrals

$$\int_0^x \frac{1 - J_0(t)}{t} dt$$
$$\int_x^\infty \frac{Y_0(t)}{t} dt.$$

For more on J_0 and Y_0 see j0 and y0.

Parameters

x [array_like] Values at which to evaluate the integrals.
out [tuple of ndarrays, optional] Optional output arrays for the function results.

Returns

ij0 [scalar or ndarray] The integral for j0
iy0 [scalar or ndarray] The integral for y0

scipy.special.iti0k0

scipy.special.**iti0k0**(*x*, *out=None*) **= <ufunc 'iti0k0'>**

Integrals of modified Bessel functions of order 0.

Computes the integrals

$$\int_0^x I_0(t)dt$$
$$\int_0^x K_0(t)dt.$$

For more on I_0 and K_0 see *i0* and *k0*.

Parameters

x	[array_like] Values at which to evaluate the integrals.
out	[tuple of ndarrays, optional] Optional output arrays for the function results.

Returns

ii0	[scalar or ndarray] The integral for *i0*
ik0	[scalar or ndarray] The integral for *k0*

scipy.special.it2i0k0

scipy.special.**it2i0k0**(*x*, *out=None*) **= <ufunc 'it2i0k0'>**

Integrals related to modified Bessel functions of order 0.

Computes the integrals

$$\int_0^x \frac{I_0(t)-1}{t}dt$$
$$\int_x^\infty \frac{K_0(t)}{t}dt.$$

Parameters

x	[array_like] Values at which to evaluate the integrals.
out	[tuple of ndarrays, optional] Optional output arrays for the function results.

Returns

ii0	[scalar or ndarray] The integral for *i0*
ik0	[scalar or ndarray] The integral for *k0*

scipy.special.besselpoly

scipy.special.**besselpoly**(*a*, *lmb*, *nu*, *out=None*) **= <ufunc 'besselpoly'>**

Weighted integral of the Bessel function of the first kind.

Computes

$$\int_0^1 x^\lambda J_\nu(2ax)\,dx$$

where J_ν is a Bessel function and $\lambda = lmb$, $\nu = nu$.

Parameters

a [array_like] Scale factor inside the Bessel function.
lmb [array_like] Power of x
nu [array_like] Order of the Bessel function.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Value of the integral.

Derivatives of Bessel functions

jvp(v, z[, n])	Compute derivatives of Bessel functions of the first kind.
yvp(v, z[, n])	Compute derivatives of Bessel functions of the second kind.
kvp(v, z[, n])	Compute nth derivative of real-order modified Bessel function Kv(z)
ivp(v, z[, n])	Compute derivatives of modified Bessel functions of the first kind.
h1vp(v, z[, n])	Compute nth derivative of Hankel function H1v(z) with respect to z.
h2vp(v, z[, n])	Compute nth derivative of Hankel function H2v(z) with respect to z.

scipy.special.jvp

scipy.special.**jvp**(*v*, *z*, *n=1*)
Compute derivatives of Bessel functions of the first kind.

Compute the nth derivative of the Bessel function Jv with respect to z.

Parameters

v [float] Order of Bessel function
z [complex] Argument at which to evaluate the derivative; can be real or complex.
n [int, default 1] Order of derivative

Returns

scalar or ndarray
Values of the derivative of the Bessel function.

Notes

The derivative is computed using the relation DLFM 10.6.7 [2].

References

[1], [2]

scipy.special.yvp

scipy.special.**yvp**(*v*, *z*, *n=1*)

Compute derivatives of Bessel functions of the second kind.

Compute the nth derivative of the Bessel function *Yv* with respect to *z*.

Parameters

v	[float] Order of Bessel function
z	[complex] Argument at which to evaluate the derivative
n	[int, default 1] Order of derivative

Returns

scalar or ndarray
nth derivative of the Bessel function.

Notes

The derivative is computed using the relation DLFM 10.6.7 [2].

References

[1], [2]

scipy.special.kvp

scipy.special.**kvp**(*v*, *z*, *n=1*)

Compute nth derivative of real-order modified Bessel function Kv(z)

Kv(z) is the modified Bessel function of the second kind. Derivative is calculated with respect to *z*.

Parameters

v	[array_like of float] Order of Bessel function
z	[array_like of complex] Argument at which to evaluate the derivative
n	[int] Order of derivative. Default is first derivative.

Returns

out	[ndarray] The results

Notes

The derivative is computed using the relation DLFM 10.29.5 [2].

References

[1], [2]

Examples

Calculate multiple values at order 5:

```
>>> from scipy.special import kvp
>>> kvp(5, (1, 2, 3+5j))
array([-1.84903536e+03+0.j        , -2.57735387e+01+0.j        ,
       -3.06627741e-02+0.08750845j])
```

Calculate for a single value at multiple orders:

```
>>> kvp((4, 4.5, 5), 1)
array([ -184.0309,  -568.9585, -1849.0354])
```

scipy.special.ivp

scipy.special.**ivp**(*v*, *z*, *n=1*)

Compute derivatives of modified Bessel functions of the first kind.

Compute the nth derivative of the modified Bessel function *Iv* with respect to *z*.

Parameters

v [array_like] Order of Bessel function
z [array_like] Argument at which to evaluate the derivative; can be real or complex.
n [int, default 1] Order of derivative

Returns

scalar or ndarray
nth derivative of the modified Bessel function.

See also:

iv

Notes

The derivative is computed using the relation DLFM 10.29.5 [2].

References

[1], [2]

scipy.special.h1vp

scipy.special.**h1vp**(*v*, *z*, *n=1*)

Compute nth derivative of Hankel function H1v(z) with respect to *z*.

Parameters

v	[array_like] Order of Hankel function
z	[array_like] Argument at which to evaluate the derivative. Can be real or complex.
n	[int, default 1] Order of derivative

Returns

scalar or ndarray
Values of the derivative of the Hankel function.

Notes

The derivative is computed using the relation DLFM 10.6.7 [2].

References

[1], [2]

scipy.special.h2vp

scipy.special.**h2vp**(*v*, *z*, *n=1*)

Compute nth derivative of Hankel function H2v(z) with respect to *z*.

Parameters

v	[array_like] Order of Hankel function
z	[array_like] Argument at which to evaluate the derivative. Can be real or complex.
n	[int, default 1] Order of derivative

Returns

scalar or ndarray
Values of the derivative of the Hankel function.

Notes

The derivative is computed using the relation DLFM 10.6.7 [2].

References

[1], [2]

Spherical Bessel functions

spherical_jn(n, z[, derivative])	Spherical Bessel function of the first kind or its derivative.
spherical_yn(n, z[, derivative])	Spherical Bessel function of the second kind or its derivative.
spherical_in(n, z[, derivative])	Modified spherical Bessel function of the first kind or its derivative.
spherical_kn(n, z[, derivative])	Modified spherical Bessel function of the second kind or its derivative.

scipy.special.spherical_jn

scipy.special.**spherical_jn**(*n*, *z*, *derivative=False*)

Spherical Bessel function of the first kind or its derivative.

Defined as [1],

$$j_n(z) = \sqrt{\frac{\pi}{2z}} J_{n+1/2}(z),$$

where J_n is the Bessel function of the first kind.

Parameters

n	[int, array_like] Order of the Bessel function (n >= 0).
z	[complex or float, array_like] Argument of the Bessel function.
derivative	[bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

Returns

jn	[ndarray]

Notes

For real arguments greater than the order, the function is computed using the ascending recurrence [2]. For small real or complex arguments, the definitional relation to the cylindrical Bessel function of the first kind is used.

The derivative is computed using the relations [3],

$$j_n'(z) = j_{n-1}(z) - \frac{n+1}{z} j_n(z).$$
$$j_0'(z) = -j_1(z)$$

New in version 0.18.0.

References

[1], [2], [3]

scipy.special.spherical_yn

scipy.special.**spherical_yn**(*n*, *z*, *derivative=False*)

Spherical Bessel function of the second kind or its derivative.

Defined as [1],

$$y_n(z) = \sqrt{\frac{\pi}{2z}} Y_{n+1/2}(z),$$

where Y_n is the Bessel function of the second kind.

Parameters

n	[int, array_like] Order of the Bessel function (n >= 0).
z	[complex or float, array_like] Argument of the Bessel function.
derivative	[bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

Returns

yn	[ndarray]

Notes

For real arguments, the function is computed using the ascending recurrence [2]. For complex arguments, the definitional relation to the cylindrical Bessel function of the second kind is used.

The derivative is computed using the relations [3],

$$y_n' = y_{n-1} - \frac{n+1}{z} y_n.$$
$$y_0' = -y_1$$

New in version 0.18.0.

References

[1], [2], [3]

scipy.special.spherical_in

scipy.special.**spherical_in**(*n*, *z*, *derivative=False*)

Modified spherical Bessel function of the first kind or its derivative.

Defined as [1],

$$i_n(z) = \sqrt{\frac{\pi}{2z}} I_{n+1/2}(z),$$

where I_n is the modified Bessel function of the first kind.

Parameters

n [int, array_like] Order of the Bessel function (n >= 0).
z [complex or float, array_like] Argument of the Bessel function.
derivative [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

Returns

in [ndarray]

Notes

The function is computed using its definitional relation to the modified cylindrical Bessel function of the first kind.

The derivative is computed using the relations [2],

$$i'_n = i_{n-1} - \frac{n+1}{z} i_n.$$
$$i'_1 = i_0$$

New in version 0.18.0.

References

[1], [2]

scipy.special.spherical_kn

scipy.special.**spherical_kn**(*n*, *z*, *derivative=False*)
Modified spherical Bessel function of the second kind or its derivative.

Defined as [1],

$$k_n(z) = \sqrt{\frac{\pi}{2z}} K_{n+1/2}(z),$$

where K_n is the modified Bessel function of the second kind.

Parameters

n [int, array_like] Order of the Bessel function (n >= 0).
z [complex or float, array_like] Argument of the Bessel function.
derivative [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

Returns

kn [ndarray]

Notes

The function is computed using its definitional relation to the modified cylindrical Bessel function of the second kind.

The derivative is computed using the relations [2],

$$k'_n = -k_{n-1} - \frac{n+1}{z} k_n.$$
$$k'_0 = -k_1$$

New in version 0.18.0.

References

[1], [2]

Riccati-Bessel functions

These are not universal functions:

riccati_jn(n, x)	Compute Ricatti-Bessel function of the first kind and its derivative.
riccati_yn(n, x)	Compute Ricatti-Bessel function of the second kind and its derivative.

scipy.special.riccati_jn

scipy.special.**riccati_jn**(*n*, *x*)

Compute Ricatti-Bessel function of the first kind and its derivative.

The Ricatti-Bessel function of the first kind is defined as $xj_n(x)$, where j_n is the spherical Bessel function of the first kind of order n.

This function computes the value and first derivative of the Ricatti-Bessel function for all orders up to and including *n*.

Parameters

n	[int] Maximum order of function to compute
x	[float] Argument at which to evaluate

Returns

jn	[ndarray] Value of j0(x), …, jn(x)
jnp	[ndarray] First derivative j0’(x), …, jn’(x)

Notes

The computation is carried out via backward recurrence, using the relation DLMF 10.51.1 [2].

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

References

[1], [2]

scipy.special.riccati_yn

scipy.special.**riccati_yn**(*n*, *x*)

Compute Ricatti-Bessel function of the second kind and its derivative.

The Ricatti-Bessel function of the second kind is defined as $xy_n(x)$, where y_n is the spherical Bessel function of the second kind of order n.

This function computes the value and first derivative of the function for all orders up to and including *n*.

Parameters

n	[int] Maximum order of function to compute
x	[float] Argument at which to evaluate

Returns

yn	[ndarray] Value of y0(x), …, yn(x)
ynp	[ndarray] First derivative y0'(x), …, yn'(x)

Notes

The computation is carried out via ascending recurrence, using the relation DLMF 10.51.1 [2].

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

[1], [2]

Struve functions

struve(v, x)	Struve function.
modstruve(v, x)	Modified Struve function.
itstruve0(x)	Integral of the Struve function of order 0.
it2struve0(x)	Integral related to the Struve function of order 0.
itmodstruve0(x)	Integral of the modified Struve function of order 0.

scipy.special.struve

scipy.special.**struve**(*v*, *x*) **= <ufunc 'struve'>**

Struve function.

Return the value of the Struve function of order *v* at *x*. The Struve function is defined as,

$$H_v(x) = (z/2)^{v+1} \sum_{n=0}^{\infty} \frac{(-1)^n (z/2)^{2n}}{\Gamma(n+\frac{3}{2})\Gamma(n+v+\frac{3}{2})},$$

where Γ is the gamma function.

Parameters

v	[array_like] Order of the Struve function (float).
x	[array_like] Argument of the Struve function (float; must be positive unless *v* is an integer).

Returns

H [ndarray] Value of the Struve function of order *v* at *x*.

See also:

`modstruve`

Notes

Three methods discussed in [1] are used to evaluate the Struve function:

- power series
- expansion in Bessel functions (if $|z| < |v| + 20$)
- asymptotic large-z expansion (if $z \geq 0.7v + 12$)

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

References

[1]

scipy.special.modstruve

scipy.special.**modstruve**(*v*, *x*) **= <ufunc 'modstruve'>**

Modified Struve function.

Return the value of the modified Struve function of order *v* at *x*. The modified Struve function is defined as,

$$L_v(x) = -\imath \exp(-\pi\imath v/2) H_v(\imath x),$$

where H_v is the Struve function.

Parameters

v [array_like] Order of the modified Struve function (float).
x [array_like] Argument of the Struve function (float; must be positive unless *v* is an integer).

Returns

L [ndarray] Value of the modified Struve function of order *v* at *x*.

See also:

`struve`

Notes

Three methods discussed in [1] are used to evaluate the function:

- power series
- expansion in Bessel functions (if $|x| < |v| + 20$)
- asymptotic large-x expansion (if $x \geq 0.7v + 12$)

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

References

[1]

scipy.special.itstruve0

scipy.special.**itstruve0**(*x*) **= <ufunc 'itstruve0'>**

Integral of the Struve function of order 0.

$$I = \int_0^x H_0(t)\,dt$$

Parameters

x [array_like] Upper limit of integration (float).

Returns

I [ndarray] The integral of H_0 from 0 to x.

See also:

struve

Notes

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

References

[1]

scipy.special.it2struve0

scipy.special.**it2struve0**(*x*) **= <ufunc 'it2struve0'>**

Integral related to the Struve function of order 0.

Returns the integral,

$$\int_x^\infty \frac{H_0(t)}{t}\,dt$$

where H_0 is the Struve function of order 0.

Parameters

x [array_like] Lower limit of integration.

Returns

I [ndarray] The value of the integral.

See also:

struve

Notes

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

References

[1]

scipy.special.itmodstruve0

scipy.special.**itmodstruve0**(*x*) **= <ufunc 'itmodstruve0'>**

Integral of the modified Struve function of order 0.

$$I = \int_0^x L_0(t)\,dt$$

Parameters

x [array_like] Upper limit of integration (float).

Returns

I [ndarray] The integral of L_0 from 0 to x.

Notes

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

kolmogi(p)	Inverse Survival Function of Kolmogorov distribution
tklmbda(x, lmbda)	Tukey-Lambda cumulative distribution function
logit(x)	Logit ufunc for ndarrays.
expit(x)	Expit (a.k.a.
boxcox(x, lmbda)	Compute the Box-Cox transformation.
boxcox1p(x, lmbda)	Compute the Box-Cox transformation of 1 + *x*.
inv_boxcox(y, lmbda)	Compute the inverse of the Box-Cox transformation.
inv_boxcox1p(y, lmbda)	Compute the inverse of the Box-Cox transformation.
owens_t(h, a)	Owen's T Function.

scipy.special.bdtr

scipy.special.**bdtr**(*k*, *n*, *p*) **= <ufunc 'bdtr'>**

Binomial distribution cumulative distribution function.

Sum of the terms 0 through *floor(k)* of the Binomial probability density.

$$\mathrm{bdtr}(k, n, p) = \sum_{j=0}^{\lfloor k \rfloor} \binom{n}{j} p^j (1-p)^{n-j}$$

Parameters

k [array_like] Number of successes (double), rounded down to the nearest integer.
n [array_like] Number of events (int).
p [array_like] Probability of success in a single event (float).

Returns

y [ndarray] Probability of *floor(k)* or fewer successes in *n* independent events with success probabilities of *p*.

Notes

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\mathrm{bdtr}(k, n, p) = I_{1-p}(n - \lfloor k \rfloor, \lfloor k \rfloor + 1).$$

Wrapper for the Cephes [1] routine *bdtr*.

References

[1]

scipy.special.bdtrc

scipy.special.**bdtrc**(*k*, *n*, *p*) **= <ufunc 'bdtrc'>**

Binomial distribution survival function.

Sum of the terms *floor(k) + 1* through *n* of the binomial probability density,

$$\mathrm{bdtrc}(k, n, p) = \sum_{j=\lfloor k \rfloor + 1}^{n} \binom{n}{j} p^j (1-p)^{n-j}$$

Parameters

k	[array_like] Number of successes (double), rounded down to nearest integer.
n	[array_like] Number of events (int)
p	[array_like] Probability of success in a single event.

Returns

y	[ndarray] Probability of *floor(k) + 1* or more successes in *n* independent events with success probabilities of *p*.

See also:

bdtr

betainc

Notes

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\mathrm{bdtrc}(k, n, p) = I_p(\lfloor k \rfloor + 1, n - \lfloor k \rfloor).$$

Wrapper for the Cephes [1] routine *bdtrc*.

References

[1]

scipy.special.bdtri

scipy.special.**bdtri**(*k*, *n*, *y*) **= <ufunc 'bdtri'>**

Inverse function to *bdtr* with respect to *p*.

Finds the event probability *p* such that the sum of the terms 0 through *k* of the binomial probability density is equal to the given cumulative probability *y*.

Parameters

k	[array_like] Number of successes (float), rounded down to the nearest integer.

n [array_like] Number of events (float)
y [array_like] Cumulative probability (probability of *k* or fewer successes in *n* events).

Returns

p [ndarray] The event probability such that *bdtr(lfloor k rfloor, n, p) = y*.

See also:

bdtr

betaincinv

Notes

The computation is carried out using the inverse beta integral function and the relation,:

```
1 - p = betaincinv(n - k, k + 1, y).
```

Wrapper for the Cephes [1] routine *bdtri*.

References

[1]

scipy.special.bdtrik

scipy.special.**bdtrik**(*y*, *n*, *p*) **= <ufunc 'bdtrik'>**
Inverse function to *bdtr* with respect to *k*.

Finds the number of successes *k* such that the sum of the terms 0 through *k* of the Binomial probability density for *n* events with probability *p* is equal to the given cumulative probability *y*.

Parameters

y [array_like] Cumulative probability (probability of *k* or fewer successes in *n* events).
n [array_like] Number of events (float).
p [array_like] Success probability (float).

Returns

k [ndarray] The number of successes *k* such that *bdtr(k, n, p) = y*.

See also:

bdtr

Notes

Formula 26.5.24 of [1] is used to reduce the binomial distribution to the cumulative incomplete beta distribution.

Computation of *k* involves a search for a value that produces the desired value of *y*. The search relies on the monotonicity of *y* with *k*.

Wrapper for the CDFLIB [2] Fortran routine *cdfbin*.

References

[1], [2]

scipy.special.bdtrin

scipy.special.**bdtrin**(*k*, *y*, *p*) **= <ufunc 'bdtrin'>**

Inverse function to *bdtr* with respect to *n*.

Finds the number of events *n* such that the sum of the terms 0 through *k* of the Binomial probability density for events with probability *p* is equal to the given cumulative probability *y*.

Parameters

k	[array_like] Number of successes (float).
y	[array_like] Cumulative probability (probability of *k* or fewer successes in *n* events).
p	[array_like] Success probability (float).

Returns

n	[ndarray] The number of events *n* such that *bdtr(k, n, p) = y*.

See also:

bdtr

Notes

Formula 26.5.24 of [1] is used to reduce the binomial distribution to the cumulative incomplete beta distribution.

Computation of *n* involves a search for a value that produces the desired value of *y*. The search relies on the monotonicity of *y* with *n*.

Wrapper for the CDFLIB [2] Fortran routine *cdfbin*.

References

[1], [2]

scipy.special.btdtr

scipy.special.**btdtr**(*a*, *b*, *x*) **= <ufunc 'btdtr'>**

Cumulative distribution function of the beta distribution.

Returns the integral from zero to *x* of the beta probability density function,

$$I = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1}(1-t)^{b-1}\,dt$$

where Γ is the gamma function.

Parameters

a	[array_like] Shape parameter (a > 0).
b	[array_like] Shape parameter (b > 0).
x	[array_like] Upper limit of integration, in [0, 1].

Returns

I	[ndarray] Cumulative distribution function of the beta distribution with parameters *a* and *b* at *x*.

See also:

`betainc`

Notes

This function is identical to the incomplete beta integral function `betainc`.

Wrapper for the Cephes [1] routine `btdtr`.

References

[1]

scipy.special.btdtri

scipy.special.**btdtri**(*a*, *b*, *p*) **= <ufunc 'btdtri'>**

The *p*-th quantile of the beta distribution.

This function is the inverse of the beta cumulative distribution function, `btdtr`, returning the value of *x* for which *btdtr(a, b, x)* = *p*, or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1}(1-t)^{b-1}\,dt$$

Parameters

a	[array_like] Shape parameter ($a > 0$).
b	[array_like] Shape parameter ($b > 0$).
p	[array_like] Cumulative probability, in [0, 1].

Returns

x	[ndarray] The quantile corresponding to *p*.

See also:

betaincinv

btdtr

Notes

The value of *x* is found by interval halving or Newton iterations.

Wrapper for the Cephes [1] routine *incbi*, which solves the equivalent problem of finding the inverse of the incomplete beta integral.

References

[1]

scipy.special.btdtria

scipy.special.**btdtria**(*p*, *b*, *x*) **= <ufunc 'btdtria'>**

Inverse of *btdtr* with respect to *a*.

This is the inverse of the beta cumulative distribution function, *btdtr*, considered as a function of *a*, returning the value of *a* for which *btdtr(a, b, x)* = *p*, or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1}(1-t)^{b-1}\,dt$$

Parameters

p	[array_like] Cumulative probability, in [0, 1].
b	[array_like] Shape parameter ($b > 0$).
x	[array_like] The quantile, in [0, 1].

Returns

a	[ndarray] The value of the shape parameter *a* such that *btdtr(a, b, x)* = *p*.

See also:

btdtr

Cumulative distribution function of the beta distribution.

btdtri

Inverse with respect to *x*.

btdtrib

Inverse with respect to *b*.

Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfbet*.

The cumulative distribution function *p* is computed using a routine by DiDinato and Morris [2]. Computation of *a* involves a search for a value that produces the desired value of *p*. The search relies on the monotonicity of *p* with *a*.

References

[1], [2]

scipy.special.btdtrib

scipy.special.**btdtrib**(*a*, *p*, *x*) **= <ufunc 'btdtrib'>**

Inverse of `btdtr` with respect to *b*.

This is the inverse of the beta cumulative distribution function, `btdtr`, considered as a function of *b*, returning the value of *b* for which *btdtr(a, b, x)* = *p*, or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1}(1-t)^{b-1}\,dt$$

Parameters

a	[array_like] Shape parameter ($a > 0$).
p	[array_like] Cumulative probability, in [0, 1].
x	[array_like] The quantile, in [0, 1].

Returns

b	[ndarray] The value of the shape parameter *b* such that *btdtr(a, b, x)* = *p*.

See also:

btdtr

Cumulative distribution function of the beta distribution.

btdtri

Inverse with respect to *x*.

btdtria

Inverse with respect to *a*.

Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfbet*.

The cumulative distribution function *p* is computed using a routine by DiDinato and Morris [2]. Computation of *b* involves a search for a value that produces the desired value of *p*. The search relies on the monotonicity of *p* with *b*.

References

[1], [2]

scipy.special.fdtr

scipy.special.**fdtr**(*dfn*, *dfd*, *x*) **= <ufunc 'fdtr'>**

F cumulative distribution function.

Returns the value of the cumulative distribution function of the F-distribution, also known as Snedecor's F-distribution or the Fisher-Snedecor distribution.

The F-distribution with parameters d_n and d_d is the distribution of the random variable,

$$X = \frac{U_n/d_n}{U_d/d_d},$$

where U_n and U_d are random variables distributed χ^2, with d_n and d_d degrees of freedom, respectively.

Parameters

dfn	[array_like] First parameter (positive float).
dfd	[array_like] Second parameter (positive float).
x	[array_like] Argument (nonnegative float).

Returns

y	[ndarray] The CDF of the F-distribution with parameters *dfn* and *dfd* at *x*.

Notes

The regularized incomplete beta function is used, according to the formula,

$$F(d_n, d_d; x) = I_{xd_n/(d_d+xd_n)}(d_n/2, d_d/2).$$

Wrapper for the Cephes [1] routine `fdtr`.

References

[1]

scipy.special.fdtrc

scipy.special.**fdtrc**(*dfn*, *dfd*, *x*) **= <ufunc 'fdtrc'>**

F survival function.

Returns the complemented F-distribution function (the integral of the density from *x* to infinity).

Parameters

dfn	[array_like] First parameter (positive float).
dfd	[array_like] Second parameter (positive float).
x	[array_like] Argument (nonnegative float).

Returns

y [ndarray] The complemented F-distribution function with parameters *dfn* and *dfd* at *x*.

See also:

`fdtr`

Notes

The regularized incomplete beta function is used, according to the formula,

$$F(d_n, d_d; x) = I_{d_d/(d_d+xd_n)}(d_d/2, d_n/2).$$

Wrapper for the Cephes [1] routine `fdtrc`.

References

[1]

scipy.special.fdtri

scipy.special.**fdtri**(*dfn*, *dfd*, *p*) **= <ufunc 'fdtri'>**

The *p*-th quantile of the F-distribution.

This function is the inverse of the F-distribution CDF, `fdtr`, returning the *x* such that *fdtr(dfn, dfd, x) = p*.

Parameters

dfn [array_like] First parameter (positive float).
dfd [array_like] Second parameter (positive float).
p [array_like] Cumulative probability, in [0, 1].

Returns

x [ndarray] The quantile corresponding to *p*.

Notes

The computation is carried out using the relation to the inverse regularized beta function, $I_x^{-1}(a, b)$. Let $z = I_p^{-1}(d_d/2, d_n/2)$. Then,

$$x = \frac{d_d(1-z)}{d_n z}.$$

If *p* is such that $x < 0.5$, the following relation is used instead for improved stability: let $z' = I_{1-p}^{-1}(d_n/2, d_d/2)$. Then,

$$x = \frac{d_d z'}{d_n(1-z')}.$$

Wrapper for the Cephes [1] routine `fdtri`.

References

[1]

scipy.special.fdtridfd

scipy.special.**fdtridfd**(*dfn*, *p*, *x*) **= <ufunc 'fdtridfd'>**
Inverse to *fdtr* vs dfd

Finds the F density argument dfd such that `fdtr(dfn, dfd, x) == p`.

scipy.special.gdtr

scipy.special.**gdtr**(*a*, *b*, *x*) **= <ufunc 'gdtr'>**
Gamma distribution cumulative distribution function.

Returns the integral from zero to *x* of the gamma probability density function,

$$F = \int_0^x \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at}\,dt,$$

where Γ is the gamma function.

Parameters

a	[array_like] The rate parameter of the gamma distribution, sometimes denoted β (float). It is also the reciprocal of the scale parameter θ.
b	[array_like] The shape parameter of the gamma distribution, sometimes denoted α (float).
x	[array_like] The quantile (upper limit of integration; float).

Returns

F	[ndarray] The CDF of the gamma distribution with parameters *a* and *b* evaluated at *x*.

See also:

gdtrc

1 - CDF of the gamma distribution.

Notes

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function).

Wrapper for the Cephes [1] routine *gdtr*.

References

[1]

scipy.special.gdtrc

scipy.special.**gdtrc**(*a*, *b*, *x*) **= <ufunc 'gdtrc'>**

Gamma distribution survival function.

Integral from *x* to infinity of the gamma probability density function,

$$F = \int_x^\infty \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at}\,dt,$$

where Γ is the gamma function.

Parameters

a	[array_like] The rate parameter of the gamma distribution, sometimes denoted β (float). It is also the reciprocal of the scale parameter θ.
b	[array_like] The shape parameter of the gamma distribution, sometimes denoted α (float).
x	[array_like] The quantile (lower limit of integration; float).

Returns

F	[ndarray] The survival function of the gamma distribution with parameters *a* and *b* evaluated at *x*.

See also:

gdtr, **gdtrix**

Notes

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function).

Wrapper for the Cephes [1] routine *gdtrc*.

References

[1]

scipy.special.gdtria

scipy.special.**gdtria**(*p*, *b*, *x*, *out=None*) **= <ufunc 'gdtria'>**

Inverse of *gdtr* vs a.

Returns the inverse with respect to the parameter *a* of `p = gdtr(a, b, x)`, the cumulative distribution function of the gamma distribution.

Parameters

p	[array_like] Probability values.
b	[array_like] *b* parameter values of *gdtr(a, b, x)*. *b* is the "shape" parameter of the gamma distribution.
x	[array_like] Nonnegative real values, from the domain of the gamma distribution.
out	[ndarray, optional] If a fourth argument is given, it must be a numpy.ndarray whose size matches the broadcast result of *a*, *b* and *x*. *out* is then the array returned by the function.

Returns

a [ndarray] Values of the *a* parameter such that *p = gdtr(a, b, x)*. *1/a* is the "scale" parameter of the gamma distribution.

See also:

gdtr

CDF of the gamma distribution.

gdtrib

Inverse with respect to *b* of *gdtr(a, b, x)*.

gdtrix

Inverse with respect to *x* of *gdtr(a, b, x)*.

Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfgam*.

The cumulative distribution function *p* is computed using a routine by DiDinato and Morris [2]. Computation of *a* involves a search for a value that produces the desired value of *p*. The search relies on the monotonicity of *p* with *a*.

References

[1], [2]

Examples

First evaluate *gdtr*.

```
>>> from scipy.special import gdtr, gdtria
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```
>>> gdtria(p, 3.4, 5.6)
1.2
```

scipy.special.gdtrib

scipy.special.**gdtrib**(*a*, *p*, *x*, *out=None*) **= <ufunc 'gdtrib'>**

Inverse of *gdtr* vs b.

Returns the inverse with respect to the parameter *b* of `p = gdtr(a, b, x)`, the cumulative distribution function of the gamma distribution.

Parameters

a [array_like] *a* parameter values of *gdtr(a, b, x)*. *1/a* is the "scale" parameter of the gamma distribution.

p	[array_like] Probability values.
x	[array_like] Nonnegative real values, from the domain of the gamma distribution.
out	[ndarray, optional] If a fourth argument is given, it must be a numpy.ndarray whose size matches the broadcast result of *a*, *b* and *x*. *out* is then the array returned by the function.

Returns

b	[ndarray] Values of the *b* parameter such that *p = gdtr(a, b, x)*. *b* is the "shape" parameter of the gamma distribution.

See also:

gdtr

CDF of the gamma distribution.

gdtria

Inverse with respect to *a* of *gdtr(a, b, x)*.

gdtrix

Inverse with respect to *x* of *gdtr(a, b, x)*.

Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfgam*.

The cumulative distribution function *p* is computed using a routine by DiDinato and Morris [2]. Computation of *b* involves a search for a value that produces the desired value of *p*. The search relies on the monotonicity of *p* with *b*.

References

[1], [2]

Examples

First evaluate *gdtr*.

```
>>> from scipy.special import gdtr, gdtrib
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```
>>> gdtrib(1.2, p, 5.6)
3.3999999999723882
```

scipy.special.gdtrix

scipy.special.**gdtrix**(*a*, *b*, *p*, *out=None*) **= <ufunc 'gdtrix'>**

Inverse of *gdtr* vs x.

Returns the inverse with respect to the parameter *x* of `p = gdtr(a, b, x)`, the cumulative distribution function of the gamma distribution. This is also known as the pth quantile of the distribution.

Parameters

a	[array_like] *a* parameter values of *gdtr(a, b, x)*. *1/a* is the "scale" parameter of the gamma distribution.
b	[array_like] *b* parameter values of *gdtr(a, b, x)*. *b* is the "shape" parameter of the gamma distribution.
p	[array_like] Probability values.
out	[ndarray, optional] If a fourth argument is given, it must be a numpy.ndarray whose size matches the broadcast result of *a*, *b* and *x*. *out* is then the array returned by the function.

Returns

x	[ndarray] Values of the *x* parameter such that *p* = *gdtr(a, b, x)*.

See also:

gdtr

CDF of the gamma distribution.

gdtria

Inverse with respect to *a* of *gdtr(a, b, x)*.

gdtrib

Inverse with respect to *b* of *gdtr(a, b, x)*.

Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfgam*.

The cumulative distribution function *p* is computed using a routine by DiDinato and Morris [2]. Computation of *x* involves a search for a value that produces the desired value of *p*. The search relies on the monotonicity of *p* with *x*.

References

[1], [2]

Examples

First evaluate *gdtr*.

```
>>> from scipy.special import gdtr, gdtrix
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```
>>> gdtrix(1.2, 3.4, p)
5.5999999999999996
```

scipy.special.nbdtr

scipy.special.**nbdtr**(*k*, *n*, *p*) **= <ufunc 'nbdtr'>**

Negative binomial cumulative distribution function.

Returns the sum of the terms 0 through *k* of the negative binomial distribution probability mass function,

$$F = \sum_{j=0}^{k} \binom{n+j-1}{j} p^n (1-p)^j.$$

In a sequence of Bernoulli trials with individual success probabilities *p*, this is the probability that *k* or fewer failures precede the nth success.

Parameters

k	[array_like] The maximum number of allowed failures (nonnegative int).
n	[array_like] The target number of successes (positive int).
p	[array_like] Probability of success in a single event (float).

Returns

F	[ndarray] The probability of *k* or fewer failures before *n* successes in a sequence of events with individual success probability *p*.

See also:

nbdtrc

Notes

If floating point values are passed for *k* or *n*, they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\mathrm{nbdtr}(k, n, p) = I_p(n, k+1).$$

Wrapper for the Cephes [1] routine *nbdtr*.

References

[1]

scipy.special.nbdtrc

scipy.special.**nbdtrc**(*k*, *n*, *p*) **= <ufunc 'nbdtrc'>**

Negative binomial survival function.

Returns the sum of the terms *k + 1* to infinity of the negative binomial distribution probability mass function,

$$F = \sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j.$$

In a sequence of Bernoulli trials with individual success probabilities *p*, this is the probability that more than *k* failures precede the nth success.

Parameters

k [array_like] The maximum number of allowed failures (nonnegative int).
n [array_like] The target number of successes (positive int).
p [array_like] Probability of success in a single event (float).

Returns

F [ndarray] The probability of *k + 1* or more failures before *n* successes in a sequence of events with individual success probability *p*.

Notes

If floating point values are passed for *k* or *n*, they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\mathrm{nbdtrc}(k, n, p) = I_{1-p}(k+1, n).$$

Wrapper for the Cephes [1] routine *nbdtrc*.

References

[1]

scipy.special.nbdtri

scipy.special.**nbdtri**(*k*, *n*, *y*) **= <ufunc 'nbdtri'>**

Inverse of *nbdtr* vs *p*.

Returns the inverse with respect to the parameter *p* of *y = nbdtr(k, n, p)*, the negative binomial cumulative distribution function.

Parameters

k [array_like] The maximum number of allowed failures (nonnegative int).
n [array_like] The target number of successes (positive int).

y [array_like] The probability of *k* or fewer failures before *n* successes (float).

Returns

p [ndarray] Probability of success in a single event (float) such that *nbdtr(k, n, p) = y*.

See also:

nbdtr

Cumulative distribution function of the negative binomial.

nbdtrik

Inverse with respect to *k* of *nbdtr(k, n, p)*.

nbdtrin

Inverse with respect to *n* of *nbdtr(k, n, p)*.

Notes

Wrapper for the Cephes [1] routine *nbdtri*.

References

[1]

scipy.special.nbdtrik

scipy.special.**nbdtrik**(*y*, *n*, *p*) **= <ufunc 'nbdtrik'>**

Inverse of *nbdtr* vs *k*.

Returns the inverse with respect to the parameter *k* of *y = nbdtr(k, n, p)*, the negative binomial cumulative distribution function.

Parameters

y [array_like] The probability of *k* or fewer failures before *n* successes (float).
n [array_like] The target number of successes (positive int).
p [array_like] Probability of success in a single event (float).

Returns

k [ndarray] The maximum number of allowed failures such that *nbdtr(k, n, p) = y*.

See also:

nbdtr

Cumulative distribution function of the negative binomial.

nbdtri

Inverse with respect to *p* of *nbdtr(k, n, p)*.

nbdtrin

Inverse with respect to *n* of *nbdtr(k, n, p)*.

Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfnbn*.

Formula 26.5.26 of [2],

$$\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1, n),$$

is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta I.

Computation of k involves a search for a value that produces the desired value of y. The search relies on the monotonicity of y with k.

References

[1], [2]

scipy.special.nbdtrin

scipy.special.**nbdtrin**(*k*, *y*, *p*) **= <ufunc 'nbdtrin'>**

Inverse of *nbdtr* vs *n*.

Returns the inverse with respect to the parameter *n* of *y = nbdtr(k, n, p)*, the negative binomial cumulative distribution function.

Parameters

k	[array_like] The maximum number of allowed failures (nonnegative int).
y	[array_like] The probability of *k* or fewer failures before *n* successes (float).
p	[array_like] Probability of success in a single event (float).

Returns

n	[ndarray] The number of successes *n* such that *nbdtr(k, n, p) = y*.

See also:

nbdtr

Cumulative distribution function of the negative binomial.

nbdtri

Inverse with respect to *p* of *nbdtr(k, n, p)*.

nbdtrik

Inverse with respect to *k* of *nbdtr(k, n, p)*.

Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfnbn*.

Formula 26.5.26 of [2],

$$\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1, n),$$

is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta I.

Computation of *n* involves a search for a value that produces the desired value of *y*. The search relies on the monotonicity of *y* with *n*.

References

[1], [2]

scipy.special.ncfdtr

scipy.special.**ncfdtr**(*dfn*, *dfd*, *nc*, *f*) **= <ufunc 'ncfdtr'>**

Cumulative distribution function of the non-central F distribution.

The non-central F describes the distribution of,

$$Z = \frac{X/d_n}{Y/d_d}$$

where X and Y are independently distributed, with X distributed non-central χ^2 with noncentrality parameter *nc* and d_n degrees of freedom, and Y distributed χ^2 with d_d degrees of freedom.

Parameters

dfn	[array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).
dfd	[array_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).
nc	[array_like] Noncentrality parameter. Should be in range (0, 1e4).
f	[array_like] Quantiles, i.e. the upper limit of integration.

Returns

cdf	[float or ndarray] The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise it will be an array.

See also:

ncfdtri

Quantile function; inverse of *ncfdtr* with respect to *f*.

ncfdtridfd

Inverse of *ncfdtr* with respect to *dfd*.

ncfdtridfn

Inverse of *ncfdtr* with respect to *dfn*.

ncfdtrinc

Inverse of *ncfdtr* with respect to *nc*.

Notes

Wrapper for the CDFLIB [1] Fortran routine *cdffnc*.

The cumulative distribution function is computed using Formula 26.6.20 of [2]:

$$F(d_n, d_d, n_c, f) = \sum_{j=0}^{\infty} e^{-n_c/2} \frac{(n_c/2)^j}{j!} I_x(\frac{d_n}{2} + j, \frac{d_d}{2}),$$

where I is the regularized incomplete beta function, and $x = f d_n/(f d_n + d_d)$.

The computation time required for this routine is proportional to the noncentrality parameter *nc*. Very large values of this parameter can consume immense computer resources. This is why the search range is bounded by 10,000.

References

[1], [2]

Examples

```
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Plot the CDF of the non-central F distribution, for nc=0. Compare with the F-distribution from scipy.stats:

```
>>> x = np.linspace(-1, 8, num=500)
>>> dfn = 3
>>> dfd = 2
>>> ncf_stats = stats.f.cdf(x, dfn, dfd)
>>> ncf_special = special.ncfdtr(dfn, dfd, 0, x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, ncf_stats, 'b-', lw=3)
>>> ax.plot(x, ncf_special, 'r-')
>>> plt.show()
```

scipy.special.ncfdtridfd

scipy.special.**ncfdtridfd**(*dfn*, *p*, *nc*, *f*) **= <ufunc 'ncfdtridfd'>**

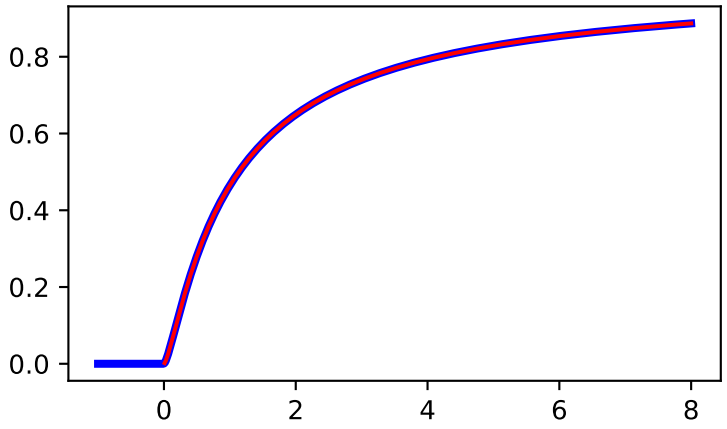
Calculate degrees of freedom (denominator) for the noncentral F-distribution.

This is the inverse with respect to *dfd* of *ncfdtr*. See *ncfdtr* for more details.

Parameters

dfn	[array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).
p	[array_like] Value of the cumulative distribution function. Must be in the range [0, 1].
nc	[array_like] Noncentrality parameter. Should be in range (0, 1e4).
f	[array_like] Quantiles, i.e., the upper limit of integration.

Returns



dfd [float] Degrees of freedom of the denominator sum of squares.

See also:

ncfdtr

CDF of the non-central F distribution.

ncfdtri

Quantile function; inverse of *ncfdtr* with respect to *f*.

ncfdtridfn

Inverse of *ncfdtr* with respect to *dfn*.

ncfdtrinc

Inverse of *ncfdtr* with respect to *nc*.

Notes

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.

Examples

```
>>> from scipy.special import ncfdtr, ncfdtridfd
```

Compute the CDF for several values of *dfd*:

```
>>> dfd = [1, 2, 3]
>>> p = ncfdtr(2, dfd, 0.25, 15)
>>> p
array([ 0.8097138 ,  0.93020416,  0.96787852])
```

Compute the inverse. We recover the values of *dfd*, as expected:

```
>>> ncfdtridfd(2, p, 0.25, 15)
array([ 1.,  2.,  3.])
```

scipy.special.ncfdtridfn

scipy.special.**ncfdtridfn**(*p*, *dfd*, *nc*, *f*) **= <ufunc 'ncfdtridfn'>**

Calculate degrees of freedom (numerator) for the noncentral F-distribution.

This is the inverse with respect to *dfn* of *ncfdtr*. See *ncfdtr* for more details.

Parameters

p	[array_like] Value of the cumulative distribution function. Must be in the range [0, 1].
dfd	[array_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).
nc	[array_like] Noncentrality parameter. Should be in range (0, 1e4).
f	[float] Quantiles, i.e., the upper limit of integration.

Returns

dfn	[float] Degrees of freedom of the numerator sum of squares.

See also:

ncfdtr

CDF of the non-central F distribution.

ncfdtri

Quantile function; inverse of *ncfdtr* with respect to *f*.

ncfdtridfd

Inverse of *ncfdtr* with respect to *dfd*.

ncfdtrinc

Inverse of *ncfdtr* with respect to *nc*.

Notes

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.

Examples

```
>>> from scipy.special import ncfdtr, ncfdtridfn
```

Compute the CDF for several values of *dfn*:

```
>>> dfn = [1, 2, 3]
>>> p = ncfdtr(dfn, 2, 0.25, 15)
>>> p
array([ 0.92562363,  0.93020416,  0.93188394])
```

Compute the inverse. We recover the values of *dfn*, as expected:

```
>>> ncfdtridfn(p, 2, 0.25, 15)
array([ 1.,  2.,  3.])
```

scipy.special.ncfdtri

scipy.special.**ncfdtri**(*dfn*, *dfd*, *nc*, *p*) **= <ufunc 'ncfdtri'>**

Inverse with respect to *f* of the CDF of the non-central F distribution.

See *ncfdtr* for more details.

Parameters

dfn	[array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).
dfd	[array_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).
nc	[array_like] Noncentrality parameter. Should be in range (0, 1e4).
p	[array_like] Value of the cumulative distribution function. Must be in the range [0, 1].

Returns

f	[float] Quantiles, i.e., the upper limit of integration.

See also:

ncfdtr

CDF of the non-central F distribution.

ncfdtridfd

Inverse of *ncfdtr* with respect to *dfd*.

ncfdtridfn

Inverse of *ncfdtr* with respect to *dfn*.

ncfdtrinc

Inverse of *ncfdtr* with respect to *nc*.

Examples

```
>>> from scipy.special import ncfdtr, ncfdtri
```

Compute the CDF for several values of *f*:

```
>>> f = [0.5, 1, 1.5]
>>> p = ncfdtr(2, 3, 1.5, f)
>>> p
array([ 0.20782291,  0.36107392,  0.47345752])
```

Compute the inverse. We recover the values of *f*, as expected:

```
>>> ncfdtri(2, 3, 1.5, p)
array([ 0.5,  1. ,  1.5])
```

scipy.special.ncfdtrinc

scipy.special.**ncfdtrinc**(*dfn*, *dfd*, *p*, *f*) **= <ufunc 'ncfdtrinc'>**

Calculate non-centrality parameter for non-central F distribution.

This is the inverse with respect to *nc* of `ncfdtr`. See `ncfdtr` for more details.

Parameters

dfn	[array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).
dfd	[array_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).
p	[array_like] Value of the cumulative distribution function. Must be in the range [0, 1].
f	[array_like] Quantiles, i.e., the upper limit of integration.

Returns

nc	[float] Noncentrality parameter.

See also:

ncfdtr

CDF of the non-central F distribution.

ncfdtri

Quantile function; inverse of `ncfdtr` with respect to *f*.

ncfdtridfd

Inverse of `ncfdtr` with respect to *dfd*.

ncfdtridfn

Inverse of `ncfdtr` with respect to *dfn*.

Examples

```
>>> from scipy.special import ncfdtr, ncfdtrinc
```

Compute the CDF for several values of *nc*:

```
>>> nc = [0.5, 1.5, 2.0]
>>> p = ncfdtr(2, 3, nc, 15)
>>> p
array([ 0.96309246,  0.94327955,  0.93304098])
```

Compute the inverse. We recover the values of *nc*, as expected:

```
>>> ncfdtrinc(2, 3, p, 15)
array([ 0.5,  1.5,  2. ])
```

scipy.special.nctdtr

scipy.special.**nctdtr**(*df*, *nc*, *t*) **= <ufunc 'nctdtr'>**

Cumulative distribution function of the non-central *t* distribution.

Parameters

df	[array_like] Degrees of freedom of the distribution. Should be in range (0, inf).
nc	[array_like] Noncentrality parameter. Should be in range (-1e6, 1e6).
t	[array_like] Quantiles, i.e., the upper limit of integration.

Returns

cdf	[float or ndarray] The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise, it will be an array.

See also:

nctdtrit

Inverse CDF (iCDF) of the non-central t distribution.

nctdtridf

Calculate degrees of freedom, given CDF and iCDF values.

nctdtrinc

Calculate non-centrality parameter, given CDF iCDF values.

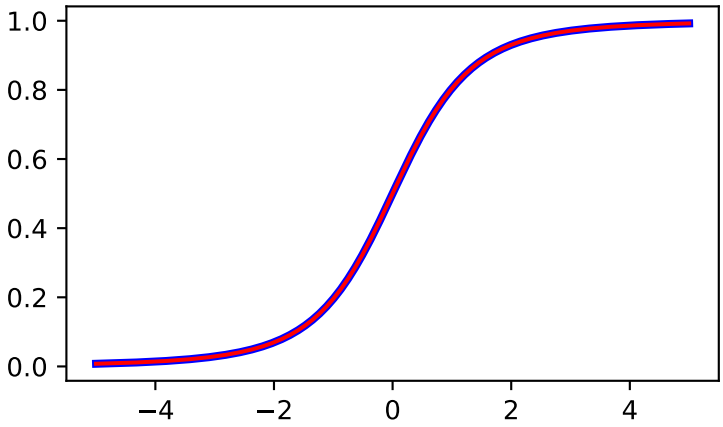
Examples

```
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Plot the CDF of the non-central t distribution, for nc=0. Compare with the t-distribution from scipy.stats:

```
>>> x = np.linspace(-5, 5, num=500)
>>> df = 3
>>> nct_stats = stats.t.cdf(x, df)
>>> nct_special = special.nctdtr(df, 0, x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, nct_stats, 'b-', lw=3)
>>> ax.plot(x, nct_special, 'r-')
>>> plt.show()
```



scipy.special.nctdtridf

scipy.special.**nctdtridf**(*p*, *nc*, *t*) **= <ufunc 'nctdtridf'>**

Calculate degrees of freedom for non-central t distribution.

See *nctdtr* for more details.

Parameters

p	[array_like] CDF values, in range (0, 1].
nc	[array_like] Noncentrality parameter. Should be in range (-1e6, 1e6).
t	[array_like] Quantiles, i.e., the upper limit of integration.

scipy.special.nctdtrit

scipy.special.**nctdtrit**(*df*, *nc*, *p*) **= <ufunc 'nctdtrit'>**

Inverse cumulative distribution function of the non-central t distribution.

See *nctdtr* for more details.

Parameters

df	[array_like] Degrees of freedom of the distribution. Should be in range (0, inf).
nc	[array_like] Noncentrality parameter. Should be in range (-1e6, 1e6).
p	[array_like] CDF values, in range (0, 1].

scipy.special.nctdtrinc

scipy.special.**nctdtrinc**(*df*, *p*, *t*) **= <ufunc 'nctdtrinc'>**

Calculate non-centrality parameter for non-central t distribution.

See *nctdtr* for more details.

Parameters

df	[array_like] Degrees of freedom of the distribution. Should be in range (0, inf).
p	[array_like] CDF values, in range (0, 1].
t	[array_like] Quantiles, i.e., the upper limit of integration.

scipy.special.nrdtrimn

scipy.special.**nrdtrimn**(*p*, *x*, *std*) **= <ufunc 'nrdtrimn'>**

Calculate mean of normal distribution given other params.

Parameters

p	[array_like] CDF values, in range (0, 1].
x	[array_like] Quantiles, i.e. the upper limit of integration.
std	[array_like] Standard deviation.

Returns

mn	[float or ndarray] The mean of the normal distribution.

See also:

nrdtrimn, **ndtr**

scipy.special.nrdtrisd

scipy.special.**nrdtrisd**(*p*, *x*, *mn*) **= <ufunc 'nrdtrisd'>**

Calculate standard deviation of normal distribution given other params.

Parameters

p	[array_like] CDF values, in range (0, 1].
x	[array_like] Quantiles, i.e. the upper limit of integration.
mn	[float or ndarray] The mean of the normal distribution.

Returns

std	[array_like] Standard deviation.

See also:

ndtr

scipy.special.pdtr

scipy.special.**pdtr**(*k*, *m*, *out=None*) **= <ufunc 'pdtr'>**

Poisson cumulative distribution function.

Defined as the probability that a Poisson-distributed random variable with event rate m is less than or equal to k. More concretely, this works out to be [1]

$$\exp(-m) \sum_{j=0}^{\lfloor k \rfloor} \frac{m^j}{m!}.$$

Parameters

k	[array_like] Nonnegative real argument
m	[array_like] Nonnegative real shape parameter
out	[ndarray] Optional output array for the function results

Returns

scalar or ndarray
Values of the Poisson cumulative distribution function

See also:

pdtrc

Poisson survival function

pdtrik

inverse of *pdtr* with respect to *k*

pdtri

inverse of *pdtr* with respect to *m*

References

[1]

Examples

```
>>> import scipy.special as sc
```

It is a cumulative distribution function, so it converges to 1 monotonically as *k* goes to infinity.

```
>>> sc.pdtr([1, 10, 100, np.inf], 1)
array([0.73575888, 0.99999999, 1.        , 1.        ])
```

It is discontinuous at integers and constant between integers.

```
>>> sc.pdtr([1, 1.5, 1.9, 2], 1)
array([0.73575888, 0.73575888, 0.73575888, 0.9196986 ])
```

scipy.special.pdtrc

scipy.special.**pdtrc**(*k*, *m*) **= <ufunc 'pdtrc'>**
Poisson survival function

Returns the sum of the terms from k+1 to infinity of the Poisson distribution: sum(exp(-m) * m**j / j!, j=k+1..inf) = gammainc(k+1, m). Arguments must both be non-negative doubles.

scipy.special.pdtri

scipy.special.**pdtri**(*k*, *y*) **= <ufunc 'pdtri'>**
Inverse to *pdtr* vs m

Returns the Poisson variable *m* such that the sum from 0 to *k* of the Poisson density is equal to the given probability *y*: calculated by gammaincinv(k+1, y). *k* must be a nonnegative integer and *y* between 0 and 1.

scipy.special.pdtrik

scipy.special.**pdtrik**(*p*, *m*) **= <ufunc 'pdtrik'>**
Inverse to *pdtr* vs k

Returns the quantile k such that `pdtr(k, m) = p`

scipy.special.stdtr

scipy.special.**stdtr**(*df*, *t*) **= <ufunc 'stdtr'>**
Student t distribution cumulative distribution function

Returns the integral from minus infinity to t of the Student t distribution with df > 0 degrees of freedom:

```
gamma((df+1)/2)/(sqrt(df*pi)*gamma(df/2)) *
integral((1+x**2/df)**(-df/2-1/2), x=-inf..t)
```

scipy.special.stdtridf

scipy.special.**stdtridf**(*p*, *t*) **= <ufunc 'stdtridf'>**
Inverse of *stdtr* vs df

Returns the argument df such that stdtr(df, t) is equal to *p*.

scipy.special.stdtrit

scipy.special.**stdtrit**(*df*, *p*) **= <ufunc 'stdtrit'>**
Inverse of *stdtr* vs *t*

Returns the argument *t* such that stdtr(df, t) is equal to *p*.

scipy.special.chdtr

scipy.special.**chdtr**(*v*, *x*, *out=None*) **= <ufunc 'chdtr'>**

Chi square cumulative distribution function.

Returns the area under the left tail (from 0 to *x*) of the Chi square probability density function with *v* degrees of freedom:

$$\frac{1}{2^{v/2}\Gamma(v/2)} \int_0^x t^{v/2-1} e^{-t/2} dt$$

Here Γ is the Gamma function; see *gamma*. This integral can be expressed in terms of the regularized lower incomplete gamma function *gammainc* as `gammainc(v / 2, x / 2)`. [1]

Parameters

v	[array_like] Degrees of freedom.
x	[array_like] Upper bound of the integral.
out	[ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Values of the cumulative distribution function.

See also:

chdtrc, **chdtri**, **chdtriv**, **gammainc**

References

[1]

Examples

```
>>> import scipy.special as sc
```

It can be expressed in terms of the regularized lower incomplete gamma function.

```
>>> v = 1
>>> x = np.arange(4)
>>> sc.chdtr(v, x)
array([0.        , 0.68268949, 0.84270079, 0.91673548])
>>> sc.gammainc(v / 2, x / 2)
array([0.        , 0.68268949, 0.84270079, 0.91673548])
```

scipy.special.chdtrc

scipy.special.**chdtrc**(*v*, *x*, *out=None*) **= <ufunc 'chdtrc'>**

Chi square survival function.

Returns the area under the right hand tail (from *x* to infinity) of the Chi square probability density function with *v* degrees of freedom:

$$\frac{1}{2^{v/2}\Gamma(v/2)} \int_x^\infty t^{v/2-1} e^{-t/2} dt$$

Here Γ is the Gamma function; see *gamma*. This integral can be expressed in terms of the regularized upper incomplete gamma function *gammaincc* as `gammaincc(v / 2, x / 2)`. [1]

Parameters

v	[array_like] Degrees of freedom.
x	[array_like] Lower bound of the integral.
out	[ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Values of the survival function.

See also:

chdtr, **chdtri**, **chdtriv**, **gammaincc**

References

[1]

Examples

```
>>> import scipy.special as sc
```

It can be expressed in terms of the regularized upper incomplete gamma function.

```
>>> v = 1
>>> x = np.arange(4)
>>> sc.chdtrc(v, x)
array([1.        , 0.31731051, 0.15729921, 0.08326452])
>>> sc.gammaincc(v / 2, x / 2)
array([1.        , 0.31731051, 0.15729921, 0.08326452])
```

scipy.special.chdtri

scipy.special.**chdtri**(*v*, *p*, *out=None*) **= <ufunc 'chdtri'>**

Inverse to *chdtrc* with respect to *x*.

Returns *x* such that `chdtrc(v, x) == p`.

Parameters

v	[array_like] Degrees of freedom.
p	[array_like] Probability.
out	[ndarray, optional] Optional output array for the function results.

Returns

x	[scalar or ndarray] Value so that the probability a Chi square random variable with *v* degrees of freedom is greater than *x* equals *p*.

See also:

chdtrc, **chdtr**, **chdtriv**

References

[1]

Examples

```
>>> import scipy.special as sc
```

It inverts *chdtrc*.

```
>>> v, p = 1, 0.3
>>> sc.chdtrc(v, sc.chdtri(v, p))
0.3
>>> x = 1
>>> sc.chdtri(v, sc.chdtrc(v, x))
1.0
```

scipy.special.chdtriv

scipy.special.**chdtriv**(*p*, *x*, *out=None*) **= <ufunc 'chdtriv'>**

Inverse to *chdtr* with respect to *v*.

Returns *v* such that `chdtr(v, x) == p`.

Parameters

p	[array_like] Probability that the Chi square random variable is less than or equal to *x*.
x	[array_like] Nonnegative input.
out	[ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray	Degrees of freedom.

See also:

chdtr, **chdtrc**, **chdtri**

References

[1]

Examples

```
>>> import scipy.special as sc
```

It inverts *chdtr*.

```
>>> p, x = 0.5, 1
>>> sc.chdtr(sc.chdtriv(p, x), x)
0.5000000000202172
>>> v = 1
>>> sc.chdtriv(sc.chdtr(v, x), v)
1.0000000000000013
```

scipy.special.ndtr

scipy.special.**ndtr**(*x*) **= <ufunc 'ndtr'>**

Gaussian cumulative distribution function.

Returns the area under the standard Gaussian probability density function, integrated from minus infinity to *x*

$$\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} \exp(-t^2/2) dt$$

Parameters

x [array_like, real or complex] Argument

Returns

ndarray The value of the normal CDF evaluated at *x*

See also:

erf

erfc

scipy.stats.norm

log_ndtr

scipy.special.log_ndtr

scipy.special.**log_ndtr**(*x*) **= <ufunc 'log_ndtr'>**

Logarithm of Gaussian cumulative distribution function.

Returns the log of the area under the standard Gaussian probability density function, integrated from minus infinity to *x*:

```
log(1/sqrt(2*pi) * integral(exp(-t**2 / 2), t=-inf..x))
```

Parameters

x [array_like, real or complex] Argument

Returns

ndarray The value of the log of the normal CDF evaluated at *x*

See also:

erf

erfc

scipy.stats.norm

ndtr

scipy.special.ndtri

scipy.special.**ndtri**(*y*) **= <ufunc 'ndtri'>**

Inverse of *ndtr* vs x

Returns the argument x for which the area under the Gaussian probability density function (integrated from minus infinity to *x*) is equal to y.

scipy.special.ndtri_exp

scipy.special.**ndtri_exp**(*y*) **= <ufunc 'ndtri_exp'>**

Inverse of *log_ndtr* vs x. Allows for greater precision than *ndtri* composed with numpy.exp for very small values of y and for y close to 0.

Parameters

y [array_like of float]

Returns

scalar or ndarray
Inverse of the log CDF of the standard normal distribution, evaluated at y.

See also:

log_ndtr, **ndtri**, **ndtr**

Examples

```
>>> import scipy.special as sc
```

ndtri_exp agrees with the naive implementation when the latter does not suffer from underflow.

```
>>> sc.ndtri_exp(-1)
-0.33747496376420244
>>> sc.ndtri(np.exp(-1))
-0.33747496376420244
```

For extreme values of y, the naive approach fails

```
>>> sc.ndtri(np.exp(-800))
-inf
>>> sc.ndtri(np.exp(-1e-20))
inf
```

whereas *ndtri_exp* is still able to compute the result to high precision.

```
>>> sc.ndtri_exp(-800)
-39.88469483825668
>>> sc.ndtri_exp(-1e-20)
9.262340089798409
```

scipy.special.chndtr

scipy.special.**chndtr**(*x*, *df*, *nc*) **= <ufunc 'chndtr'>**
Non-central chi square cumulative distribution function

scipy.special.chndtridf

scipy.special.**chndtridf**(*x*, *p*, *nc*) **= <ufunc 'chndtridf'>**
Inverse to *chndtr* vs *df*

scipy.special.chndtrinc

scipy.special.**chndtrinc**(*x*, *df*, *p*) **= <ufunc 'chndtrinc'>**
Inverse to *chndtr* vs *nc*

scipy.special.chndtrix

scipy.special.**chndtrix**(*p*, *df*, *nc*) **= <ufunc 'chndtrix'>**
Inverse to *chndtr* vs *x*

scipy.special.smirnov

scipy.special.**smirnov**(*n*, *d*) **= <ufunc 'smirnov'>**

Kolmogorov-Smirnov complementary cumulative distribution function

Returns the exact Kolmogorov-Smirnov complementary cumulative distribution function,(aka the Survival Function) of Dn+ (or Dn-) for a one-sided test of equality between an empirical and a theoretical distribution. It is equal to the probability that the maximum difference between a theoretical distribution and an empirical one based on *n* samples is greater than d.

Parameters

n	[int] Number of samples
d	[float array_like] Deviation between the Empirical CDF (ECDF) and the target CDF.

Returns

float	The value(s) of smirnov(n, d), Prob(Dn+ >= d) (Also Prob(Dn- >= d))

See also:

smirnovi

The Inverse Survival Function for the distribution

scipy.stats.ksone

Provides the functionality as a continuous distribution

kolmogorov, **kolmogi**

Functions for the two-sided distribution

Notes

smirnov is used by *stats.kstest* in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historial reasons this function is exposed in *scpy.special*, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the *stats.ksone* distribution.

Examples

```
>>> from scipy.special import smirnov
```

Show the probability of a gap at least as big as 0, 0.5 and 1.0 for a sample of size 5

```
>>> smirnov(5, [0, 0.5, 1.0])
array([ 1.   ,  0.056,  0.   ])
```

Compare a sample of size 5 drawn from a source N(0.5, 1) distribution against a target N(0, 1) CDF.

```
>>> from scipy.stats import norm
>>> rng = np.random.default_rng()
>>> n = 5
>>> gendist = norm(0.5, 1)        # Normal distribution, mean 0.5, stddev 1
>>> x = np.sort(gendist.rvs(size=n, random_state=rng))
>>> x
array([-1.3922078 , -0.13526532,  0.1371477 ,  0.18981686,  1.81948167])
```

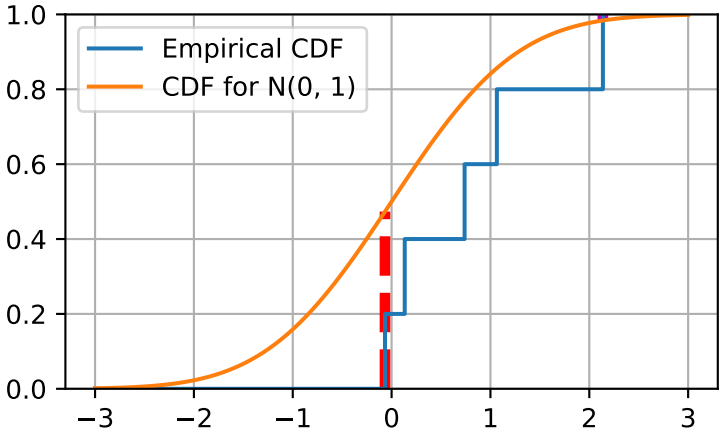
(continues on next page)

(continued from previous page)

```
>>> target = norm(0, 1)
>>> cdfs = target.cdf(x)
>>> cdfs
array([0.08192974, 0.44620105, 0.55454297, 0.57527368, 0.96558101])
# Construct the Empirical CDF and the K-S statistics (Dn+, Dn-, Dn)
>>> ecdfs = np.arange(n+1, dtype=float)/n
>>> cols = np.column_stack([x, ecdfs[1:], cdfs, cdfs - ecdfs[:n],␣
↪ecdfs[1:] - cdfs])
>>> np.set_printoptions(precision=3)
>>> cols
array([[-1.392,  0.2  ,  0.082,  0.082,  0.118],
       [-0.135,  0.4  ,  0.446,  0.246, -0.046],
       [ 0.137,  0.6  ,  0.555,  0.155,  0.045],
       [ 0.19 ,  0.8  ,  0.575, -0.025,  0.225],
       [ 1.819,  1.   ,  0.966,  0.166,  0.034]])
>>> gaps = cols[:, -2:]
>>> Dnpm = np.max(gaps, axis=0)
>>> print('Dn-=%f, Dn+=%f' % (Dnpm[0], Dnpm[1]))
Dn-=0.246201, Dn+=0.224726
>>> probs = smirnov(n, Dnpm)
>>> print(chr(10).join(['For a sample of size %d drawn from a N(0, 1)␣
↪distribution:' % n,
...       ' Smirnov n=%d: Prob(Dn- >= %f) = %.4f' % (n, Dnpm[0],␣
↪probs[0]),
...       ' Smirnov n=%d: Prob(Dn+ >= %f) = %.4f' % (n, Dnpm[1],␣
↪probs[1])]))
For a sample of size 5 drawn from a N(0, 1) distribution:
 Smirnov n=5: Prob(Dn- >= 0.246201) = 0.4713
 Smirnov n=5: Prob(Dn+ >= 0.224726) = 0.5243
```

Plot the Empirical CDF against the target N(0, 1) CDF

```
>>> import matplotlib.pyplot as plt
>>> plt.step(np.concatenate([[-3], x]), ecdfs, where='post', label=
↪'Empirical CDF')
>>> x3 = np.linspace(-3, 3, 100)
>>> plt.plot(x3, target.cdf(x3), label='CDF for N(0, 1)')
>>> plt.ylim([0, 1]); plt.grid(True); plt.legend();
# Add vertical lines marking Dn+ and Dn-
>>> iminus, iplus = np.argmax(gaps, axis=0)
>>> plt.vlines([x[iminus]], ecdfs[iminus], cdfs[iminus], color='r',␣
↪linestyle='dashed', lw=4)
>>> plt.vlines([x[iplus]], cdfs[iplus], ecdfs[iplus+1], color='m',␣
↪linestyle='dashed', lw=4)
>>> plt.show()
```



scipy.special.smirnovi

scipy.special.**smirnovi**(*n*, *p*) **= <ufunc 'smirnovi'>**

Inverse to *smirnov*

Returns *d* such that `smirnov(n, d) == p`, the critical value corresponding to *p*.

Parameters

n	[int] Number of samples
p	[float array_like] Probability

Returns

float	The value(s) of smirnovi(n, p), the critical values.

See also:

smirnov

The Survival Function (SF) for the distribution

scipy.stats.ksone

Provides the functionality as a continuous distribution

kolmogorov, **kolmogi**, **scipy.stats.kstwobign**

Functions for the two-sided distribution

Notes

smirnov is used by *stats.kstest* in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historial reasons this function is exposed in *scpy.special*, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the *stats.ksone* distribution.

scipy.special.kolmogorov

scipy.special.**kolmogorov**(*y*) **= <ufunc 'kolmogorov'>**

Complementary cumulative distribution (Survival Function) function of Kolmogorov distribution.

Returns the complementary cumulative distribution function of Kolmogorov's limiting distribution (`D_n*\ sqrt(n)` as n goes to infinity) of a two-sided test for equality between an empirical and a theoretical distribution. It is equal to the (limit as n->infinity of the) probability that `sqrt(n) * max absolute deviation > y`.

Parameters

y [float array_like] Absolute deviation between the Empirical CDF (ECDF) and the target CDF, multiplied by sqrt(n).

Returns

float The value(s) of kolmogorov(y)

See also:

kolmogi

The Inverse Survival Function for the distribution

scipy.stats.kstwobign

Provides the functionality as a continuous distribution

smirnov, **smirnovi**

Functions for the one-sided distribution

Notes

kolmogorov is used by *stats.kstest* in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historial reasons this function is exposed in *scpy.special*, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the *stats.kstwobign* distribution.

Examples

Show the probability of a gap at least as big as 0, 0.5 and 1.0.

```
>>> from scipy.special import kolmogorov
>>> from scipy.stats import kstwobign
>>> kolmogorov([0, 0.5, 1.0])
array([ 1.        ,  0.96394524,  0.26999967])
```

Compare a sample of size 1000 drawn from a Laplace(0, 1) distribution against the target distribution, a Normal(0, 1) distribution.

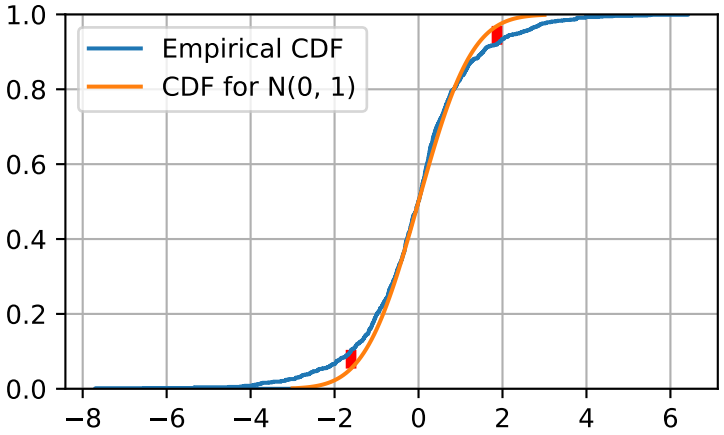
```
>>> from scipy.stats import norm, laplace
>>> rng = np.random.default_rng()
>>> n = 1000
>>> lap01 = laplace(0, 1)
>>> x = np.sort(lap01.rvs(n, random_state=rng))
>>> np.mean(x), np.std(x)
(-0.05841730131499543, 1.3968109101997568)
```

Construct the Empirical CDF and the K-S statistic Dn.

```
>>> target = norm(0,1)  # Normal mean 0, stddev 1
>>> cdfs = target.cdf(x)
>>> ecdfs = np.arange(n+1, dtype=float)/n
>>> gaps = np.column_stack([cdfs - ecdfs[:n], ecdfs[1:] - cdfs])
>>> Dn = np.max(gaps)
>>> Kn = np.sqrt(n) * Dn
>>> print('Dn=%f, sqrt(n)*Dn=%f' % (Dn, Kn))
Dn=0.043363, sqrt(n)*Dn=1.371265
>>> print(chr(10).join(['For a sample of size n drawn from a N(0, 1)␣
↪distribution:',
...   ' the approximate Kolmogorov probability that sqrt(n)*Dn>=%f is %f
↪' %  (Kn, kolmogorov(Kn)),
...   ' the approximate Kolmogorov probability that sqrt(n)*Dn<=%f is %f
↪' %  (Kn, kstwobign.cdf(Kn))]))
For a sample of size n drawn from a N(0, 1) distribution:
 the approximate Kolmogorov probability that sqrt(n)*Dn>=1.371265 is 0.
↪046533
 the approximate Kolmogorov probability that sqrt(n)*Dn<=1.371265 is 0.
↪953467
```

Plot the Empirical CDF against the target N(0, 1) CDF.

```
>>> import matplotlib.pyplot as plt
>>> plt.step(np.concatenate([[-3], x]), ecdfs, where='post', label=
↪'Empirical CDF')
>>> x3 = np.linspace(-3, 3, 100)
>>> plt.plot(x3, target.cdf(x3), label='CDF for N(0, 1)')
>>> plt.ylim([0, 1]); plt.grid(True); plt.legend();
>>> # Add vertical lines marking Dn+ and Dn-
>>> iminus, iplus = np.argmax(gaps, axis=0)
>>> plt.vlines([x[iminus]], ecdfs[iminus], cdfs[iminus], color='r',␣
↪linestyle='dashed', lw=4)
>>> plt.vlines([x[iplus]], cdfs[iplus], ecdfs[iplus+1], color='r',␣
↪linestyle='dashed', lw=4)
>>> plt.show()
```



scipy.special.kolmogi

scipy.special.**kolmogi**(*p*) **= <ufunc 'kolmogi'>**

Inverse Survival Function of Kolmogorov distribution

It is the inverse function to *kolmogorov*. Returns y such that `kolmogorov(y) == p`.

Parameters

p [float array_like] Probability

Returns

float The value(s) of kolmogi(p)

See also:

kolmogorov

The Survival Function for the distribution

scipy.stats.kstwobign

Provides the functionality as a continuous distribution

smirnov, **smirnovi**

Functions for the one-sided distribution

Notes

kolmogorov is used by *stats.kstest* in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historial reasons this function is exposed in *scpy.special*, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the *stats.kstwobign* distribution.

Examples

```
>>> from scipy.special import kolmogi
>>> kolmogi([0, 0.1, 0.25, 0.5, 0.75, 0.9, 1.0])
array([        inf,  1.22384787,  1.01918472,  0.82757356,  0.67644769,
        0.57117327,  0.        ])
```

scipy.special.tklmbda

scipy.special.**tklmbda**(*x*, *lmbda*) **= <ufunc 'tklmbda'>**

Tukey-Lambda cumulative distribution function

scipy.special.logit

scipy.special.**logit**(*x*) **= <ufunc 'logit'>**

Logit ufunc for ndarrays.

The logit function is defined as logit(p) = log(p/(1-p)). Note that logit(0) = -inf, logit(1) = inf, and logit(p) for p<0 or p>1 yields nan.

Parameters

x [ndarray] The ndarray to apply logit to element-wise.

Returns

out [ndarray] An ndarray of the same shape as x. Its entries are logit of the corresponding entry of x.

See also:

expit

Notes

As a ufunc logit takes a number of optional keyword arguments. For more information see ufuncs

New in version 0.10.0.

Examples

```
>>> from scipy.special import logit, expit
```

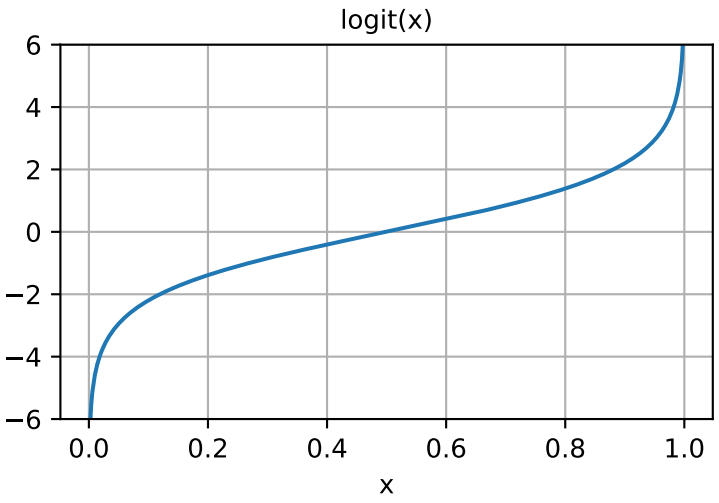
```
>>> logit([0, 0.25, 0.5, 0.75, 1])
array([       -inf, -1.09861229,  0.        ,  1.09861229,         inf])
```

expit is the inverse of *logit*:

```
>>> expit(logit([0.1, 0.75, 0.999]))
array([ 0.1  ,  0.75 ,  0.999])
```

Plot logit(x) for x in [0, 1]:

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 1, 501)
>>> y = logit(x)
>>> plt.plot(x, y)
>>> plt.grid()
>>> plt.ylim(-6, 6)
>>> plt.xlabel('x')
>>> plt.title('logit(x)')
>>> plt.show()
```



scipy.special.expit

scipy.special.**expit**(*x*) **= <ufunc 'expit'>**

Expit (a.k.a. logistic sigmoid) ufunc for ndarrays.

The expit function, also known as the logistic sigmoid function, is defined as `expit(x) = 1/(1+exp(-x))`. It is the inverse of the logit function.

Parameters

x [ndarray] The ndarray to apply expit to element-wise.

Returns

out [ndarray] An ndarray of the same shape as x. Its entries are *expit* of the corresponding entry of x.

See also:

logit

Notes

As a ufunc expit takes a number of optional keyword arguments. For more information see ufuncs

New in version 0.10.0.

Examples

```
>>> from scipy.special import expit, logit
```

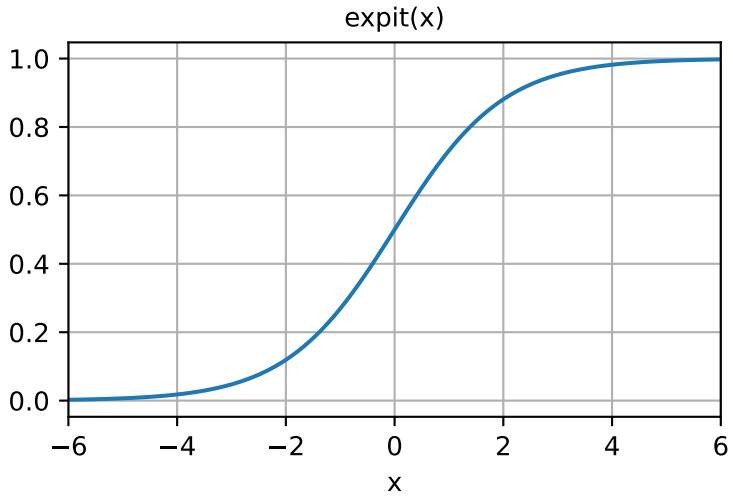
```
>>> expit([-np.inf, -1.5, 0, 1.5, np.inf])
array([ 0.        ,  0.18242552,  0.5       ,  0.81757448,  1.        ])
```

logit is the inverse of *expit*:

```
>>> logit(expit([-2.5, 0, 3.1, 5.0]))
array([-2.5,  0. ,  3.1,  5. ])
```

Plot expit(x) for x in [-6, 6]:

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-6, 6, 121)
>>> y = expit(x)
>>> plt.plot(x, y)
>>> plt.grid()
>>> plt.xlim(-6, 6)
>>> plt.xlabel('x')
>>> plt.title('expit(x)')
>>> plt.show()
```



scipy.special.boxcox

`scipy.special.`**boxcox**(*x*, *lmbda*) **= <ufunc 'boxcox'>**

Compute the Box-Cox transformation.

The Box-Cox transformation is:

```
y = (x**lmbda - 1) / lmbda  if lmbda != 0
    log(x)                  if lmbda == 0
```

Returns *nan* if `x < 0`. Returns *-inf* if `x == 0` and `lmbda < 0`.

Parameters

x	[array_like] Data to be transformed.
lmbda	[array_like] Power parameter of the Box-Cox transform.

Returns

y	[array] Transformed data.

Notes

New in version 0.14.0.

Examples

```
>>> from scipy.special import boxcox
>>> boxcox([1, 4, 10], 2.5)
array([   0.        ,   12.4       ,  126.09110641])
>>> boxcox(2, [0, 1, 2])
array([ 0.69314718,  1.        ,  1.5       ])
```

scipy.special.boxcox1p

scipy.special.**boxcox1p**(*x*, *lmbda*) **= <ufunc 'boxcox1p'>**

Compute the Box-Cox transformation of 1 + *x*.

The Box-Cox transformation computed by *boxcox1p* is:

```
y = ((1+x)**lmbda - 1) / lmbda  if lmbda != 0
    log(1+x)                    if lmbda == 0
```

Returns *nan* if `x < -1`. Returns *-inf* if `x == -1` and `lmbda < 0`.

Parameters

x [array_like] Data to be transformed.
lmbda [array_like] Power parameter of the Box-Cox transform.

Returns

y [array] Transformed data.

Notes

New in version 0.14.0.

Examples

```
>>> from scipy.special import boxcox1p
>>> boxcox1p(1e-4, [0, 0.5, 1])
array([  9.99950003e-05,   9.99975001e-05,   1.00000000e-04])
>>> boxcox1p([0.01, 0.1], 0.25)
array([ 0.00996272,  0.09645476])
```

scipy.special.inv_boxcox

scipy.special.**inv_boxcox**(*y*, *lmbda*) **= <ufunc 'inv_boxcox'>**

Compute the inverse of the Box-Cox transformation.

Find `x` such that:

```
y = (x**lmbda - 1) / lmbda  if lmbda != 0
    log(x)                  if lmbda == 0
```

Parameters

y [array_like] Data to be transformed.
lmbda [array_like] Power parameter of the Box-Cox transform.

Returns

x [array] Transformed data.

Notes

New in version 0.16.0.

Examples

```
>>> from scipy.special import boxcox, inv_boxcox
>>> y = boxcox([1, 4, 10], 2.5)
>>> inv_boxcox(y, 2.5)
array([1., 4., 10.])
```

scipy.special.inv_boxcox1p

scipy.special.**inv_boxcox1p**(*y*, *lmbda*) **= <ufunc 'inv_boxcox1p'>**

Compute the inverse of the Box-Cox transformation.

Find x such that:

```
y = ((1+x)**lmbda - 1) / lmbda  if lmbda != 0
    log(1+x)                    if lmbda == 0
```

Parameters

y [array_like] Data to be transformed.

lmbda [array_like] Power parameter of the Box-Cox transform.

Returns

x [array] Transformed data.

Notes

New in version 0.16.0.

Examples

```
>>> from scipy.special import boxcox1p, inv_boxcox1p
>>> y = boxcox1p([1, 4, 10], 2.5)
>>> inv_boxcox1p(y, 2.5)
array([1., 4., 10.])
```

scipy.special.owens_t

scipy.special.**owens_t**(*h*, *a*) **= <ufunc 'owens_t'>**

Owen's T Function.

The function T(h, a) gives the probability of the event (X > h and 0 < Y < a * X) where X and Y are independent standard normal random variables.

Parameters

h: array_like
Input value.

a: array_like
Input value.

Returns

t: scalar or ndarray
Probability of the event (X > h and 0 < Y < a * X), where X and Y are independent standard normal random variables.

References

[1]

Examples

```
>>> from scipy import special
>>> a = 3.5
>>> h = 0.78
>>> special.owens_t(h, a)
0.10877216734852274
```

Information Theory functions

entr(x)	Elementwise function for computing entropy.
rel_entr(x, y[, out])	Elementwise function for computing relative entropy.
kl_div(x, y[, out])	Elementwise function for computing Kullback-Leibler divergence.
huber(delta, r)	Huber loss function.
pseudo_huber(delta, r)	Pseudo-Huber loss function.

scipy.special.entr

scipy.special.**entr**(*x*) **= <ufunc 'entr'>**

Elementwise function for computing entropy.

$$\mathrm{entr}(x) = \begin{cases} -x\log(x) & x > 0 \\ 0 & x = 0 \\ -\infty & \text{otherwise} \end{cases}$$

Parameters

x [ndarray] Input array.

Returns

res [ndarray] The value of the elementwise entropy function at the given points *x*.

See also:

kl_div, **rel_entr**

Notes

This function is concave.

New in version 0.15.0.

scipy.special.rel_entr

scipy.special.**rel_entr**(*x*, *y*, *out=None*) **= <ufunc 'rel_entr'>**

Elementwise function for computing relative entropy.

$$\mathrm{rel_entr}(x, y) = \begin{cases} x \log(x/y) & x > 0, y > 0 \\ 0 & x = 0, y \geq 0 \\ \infty & \text{otherwise} \end{cases}$$

Parameters

x, y [array_like] Input arrays
out [ndarray, optional] Optional output array for the function results

Returns

scalar or ndarray
Relative entropy of the inputs

See also:

entr, **kl_div**

Notes

New in version 0.15.0.

This function is jointly convex in x and y.

The origin of this function is in convex programming; see [1]. Given two discrete probability distributions $p_1, \ldots, p_n$ and $q_1, \ldots, q_n$, to get the relative entropy of statistics compute the sum

$$\sum_{i=1}^{n} \mathrm{rel_entr}(p_i, q_i).$$

See [2] for details.

References

[1], [2]

scipy.special.kl_div

scipy.special.**kl_div**(*x*, *y*, *out=None*) **= <ufunc 'kl_div'>**

Elementwise function for computing Kullback-Leibler divergence.

$$\mathrm{kl_div}(x, y) = \begin{cases} x \log(x/y) - x + y & x > 0, y > 0 \\ y & x = 0, y \geq 0 \\ \infty & \text{otherwise} \end{cases}$$

Parameters

x, y [array_like] Real arguments
out [ndarray, optional] Optional output array for the function results

Returns

scalar or ndarray
Values of the Kullback-Liebler divergence.

See also:

entr, **rel_entr**

Notes

New in version 0.15.0.

This function is non-negative and is jointly convex in *x* and *y*.

The origin of this function is in convex programming; see [1] for details. This is why the the function contains the extra $-x + y$ terms over what might be expected from the Kullback-Leibler divergence. For a version of the function without the extra terms, see *rel_entr*.

References

[1]

scipy.special.huber

scipy.special.**huber**(*delta*, *r*) **= <ufunc 'huber'>**

Huber loss function.

$$\mathrm{huber}(\delta, r) = \begin{cases} \infty & \delta < 0 \\ \frac{1}{2} r^2 & 0 \leq \delta, |r| \leq \delta \\ \delta(|r| - \frac{1}{2}\delta) & \text{otherwise} \end{cases}$$

Parameters

delta [ndarray] Input array, indicating the quadratic vs. linear loss changepoint.
r [ndarray] Input array, possibly representing residuals.

Returns

res [ndarray] The computed Huber loss function values.

Notes

This function is convex in r.

New in version 0.15.0.

scipy.special.pseudo_huber

scipy.special.**pseudo_huber**(*delta*, *r*) **= <ufunc 'pseudo_huber'>**

Pseudo-Huber loss function.

$$\mathrm{pseudo_huber}(\delta, r) = \delta^2 \left(\sqrt{1 + \left(\frac{r}{\delta} \right)^2} - 1 \right)$$

Parameters

delta [ndarray] Input array, indicating the soft quadratic vs. linear loss changepoint.

r [ndarray] Input array, possibly representing residuals.

Returns

res [ndarray] The computed Pseudo-Huber loss function values.

Notes

This function is convex in r.

New in version 0.15.0.

Gamma and related functions

gamma(z)	gamma function.
gammaln(x[, out])	Logarithm of the absolute value of the gamma function.
loggamma(z[, out])	Principal branch of the logarithm of the gamma function.
gammasgn(x)	Sign of the gamma function.
gammainc(a, x)	Regularized lower incomplete gamma function.
gammaincinv(a, y)	Inverse to the lower incomplete gamma function with respect to x.
gammaincc(a, x)	Regularized upper incomplete gamma function.
gammainccinv(a, y)	Inverse of the upper incomplete gamma function with respect to x
beta(a, b[, out])	Beta function.
betaln(a, b)	Natural logarithm of absolute value of beta function.
betainc(a, b, x[, out])	Incomplete beta function.
betaincinv(a, b, y[, out])	Inverse of the incomplete beta function.
psi(z[, out])	The digamma function.
rgamma(z[, out])	Reciprocal of the gamma function.
polygamma(n, x)	Polygamma functions.

continues on next page

Table 233 – continued from previous page

multigammaln(a, d)	Returns the log of multivariate gamma, also sometimes called the generalized gamma.
digamma(z[, out])	The digamma function.
poch(z, m)	Pochhammer symbol.

scipy.special.gamma

scipy.special.**gamma**(*z*) **= <ufunc 'gamma'>**

gamma function.

The gamma function is defined as

$$\Gamma(z) = \int_0^\infty t^{z-1} e^{-t} dt$$

for $\Re(z) > 0$ and is extended to the rest of the complex plane by analytic continuation. See [dlmf] for more details.

Parameters

z [array_like] Real or complex valued argument

Returns

scalar or ndarray
Values of the gamma function

Notes

The gamma function is often referred to as the generalized factorial since $\Gamma(n+1) = n!$ for natural numbers n. More generally it satisfies the recurrence relation $\Gamma(z+1) = z \cdot \Gamma(z)$ for complex z, which, combined with the fact that $\Gamma(1) = 1$, implies the above identity for $z = n$.

References

[dlmf]

Examples

```
>>> from scipy.special import gamma, factorial
```

```
>>> gamma([0, 0.5, 1, 5])
array([         inf,   1.77245385,   1.        ,  24.        ])
```

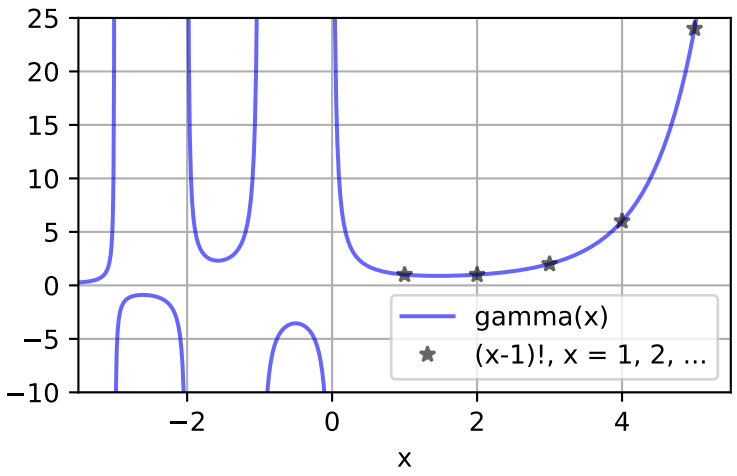
```
>>> z = 2.5 + 1j
>>> gamma(z)
(0.77476210455108352+0.70763120437959293j)
>>> gamma(z+1), z*gamma(z)  # Recurrence property
((1.2292740569981171+2.5438401155000685j),
 (1.2292740569981158+2.5438401155000658j))
```

```
>>> gamma(0.5)**2  # gamma(0.5) = sqrt(pi)
3.1415926535897927
```

Plot gamma(x) for real x

```
>>> x = np.linspace(-3.5, 5.5, 2251)
>>> y = gamma(x)
```

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'b', alpha=0.6, label='gamma(x)')
>>> k = np.arange(1, 7)
>>> plt.plot(k, factorial(k-1), 'k*', alpha=0.6,
...          label='(x-1)!, x = 1, 2, ...')
>>> plt.xlim(-3.5, 5.5)
>>> plt.ylim(-10, 25)
>>> plt.grid()
>>> plt.xlabel('x')
>>> plt.legend(loc='lower right')
>>> plt.show()
```



scipy.special.gammaln

scipy.special.**gammaln**(*x*, *out=None*) **= <ufunc 'gammaln'>**

Logarithm of the absolute value of the gamma function.

Defined as

$$\ln(|\Gamma(x)|)$$

where Γ is the gamma function. For more details on the gamma function, see [dlmf].

Parameters

x [array_like] Real argument

out [ndarray, optional] Optional output array for the function results

Returns

scalar or ndarray
Values of the log of the absolute value of gamma

See also:

gammasgn

sign of the gamma function

loggamma

principal branch of the logarithm of the gamma function

Notes

It is the same function as the Python standard library function `math.lgamma`.

When used in conjunction with *gammasgn*, this function is useful for working in logspace on the real axis without having to deal with complex numbers via the relation `exp(gammaln(x)) = gammasgn(x) * gamma(x)`.

For complex-valued log-gamma, use *loggamma* instead of *gammaln*.

References

[dlmf]

Examples

```
>>> import scipy.special as sc
```

It has two positive zeros.

```
>>> sc.gammaln([1, 2])
array([0., 0.])
```

It has poles at nonpositive integers.

```
>>> sc.gammaln([0, -1, -2, -3, -4])
array([inf, inf, inf, inf, inf])
```

It asymptotically approaches `x * log(x)` (Stirling's formula).

```
>>> x = np.array([1e10, 1e20, 1e40, 1e80])
>>> sc.gammaln(x)
array([2.20258509e+11, 4.50517019e+21, 9.11034037e+41, 1.83206807e+82])
>>> x * np.log(x)
array([2.30258509e+11, 4.60517019e+21, 9.21034037e+41, 1.84206807e+82])
```

scipy.special.loggamma

scipy.special.**loggamma**(*z*, *out=None*) **= <ufunc 'loggamma'>**

Principal branch of the logarithm of the gamma function.

Defined to be $\log(\Gamma(x))$ for $x > 0$ and extended to the complex plane by analytic continuation. The function has a single branch cut on the negative real axis.

New in version 0.18.0.

Parameters

z	[array-like] Values in the complex plain at which to compute `loggamma`
out	[ndarray, optional] Output array for computed values of `loggamma`

Returns

loggamma	[ndarray] Values of `loggamma` at z.

See also:

gammaln

logarithm of the absolute value of the gamma function

gammasgn

sign of the gamma function

Notes

It is not generally true that $\log\Gamma(z) = \log(\Gamma(z))$, though the real parts of the functions do agree. The benefit of not defining *loggamma* as $\log(\Gamma(z))$ is that the latter function has a complicated branch cut structure whereas *loggamma* is analytic except for on the negative real axis.

The identities

$$\exp(\log\Gamma(z)) = \Gamma(z)$$
$$\log\Gamma(z+1) = \log(z) + \log\Gamma(z)$$

make *loggamma* useful for working in complex logspace.

On the real line *loggamma* is related to *gammaln* via `exp(loggamma(x + 0j)) = gammasgn(x)*exp(gammaln(x))`, up to rounding error.

The implementation here is based on [hare1997].

References

[hare1997]

scipy.special.gammasgn

scipy.special.**gammasgn**(*x*) = <ufunc 'gammasgn'>

Sign of the gamma function.

It is defined as

$$\text{gammasgn}(x) = \begin{cases} +1 & \Gamma(x) > 0 \\ -1 & \Gamma(x) < 0 \end{cases}$$

where Γ is the gamma function; see *gamma*. This definition is complete since the gamma function is never zero; see the discussion after [dlmf].

Parameters

x [array_like] Real argument

Returns

scalar or ndarray
Sign of the gamma function

See also:

gamma

the gamma function

gammaln

log of the absolute value of the gamma function

loggamma

analytic continuation of the log of the gamma function

Notes

The gamma function can be computed as `gammasgn(x) * np.exp(gammaln(x))`.

References

[dlmf]

Examples

```
>>> import scipy.special as sc
```

It is 1 for $x > 0$.

```
>>> sc.gammasgn([1, 2, 3, 4])
array([1., 1., 1., 1.])
```

It alternates between -1 and 1 for negative integers.

```
>>> sc.gammasgn([-0.5, -1.5, -2.5, -3.5])
array([-1.,  1., -1.,  1.])
```

It can be used to compute the gamma function.

```
>>> x = [1.5, 0.5, -0.5, -1.5]
>>> sc.gammasgn(x) * np.exp(sc.gammaln(x))
array([ 0.88622693,  1.77245385, -3.5449077 ,  2.3632718 ])
>>> sc.gamma(x)
array([ 0.88622693,  1.77245385, -3.5449077 ,  2.3632718 ])
```

scipy.special.gammainc

scipy.special.**gammainc**(a, x) **= <ufunc 'gammainc'>**

Regularized lower incomplete gamma function.

It is defined as

$$P(a,x) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt$$

for $a > 0$ and $x \geq 0$. See [dlmf] for details.

Parameters

a [array_like] Positive parameter
x [array_like] Nonnegative argument

Returns

scalar or ndarray
Values of the lower incomplete gamma function

See also:

gammaincc

regularized upper incomplete gamma function

gammaincinv

inverse of the regularized lower incomplete gamma function with respect to x

gammainccinv

inverse of the regularized upper incomplete gamma function with respect to x

Notes

The function satisfies the relation `gammainc(a, x) + gammaincc(a, x) = 1` where *gammaincc* is the regularized upper incomplete gamma function.

The implementation largely follows that of [boost].

References

[dlmf], [boost]

Examples

```
>>> import scipy.special as sc
```

It is the CDF of the gamma distribution, so it starts at 0 and monotonically increases to 1.

```
>>> sc.gammainc(0.5, [0, 1, 10, 100])
array([0.        , 0.84270079, 0.99999226, 1.        ])
```

It is equal to one minus the upper incomplete gamma function.

```
>>> a, x = 0.5, 0.4
>>> sc.gammainc(a, x)
0.6289066304773024
>>> 1 - sc.gammaincc(a, x)
0.6289066304773024
```

scipy.special.gammaincinv

scipy.special.**gammaincinv**(*a*, *y*) **= <ufunc 'gammaincinv'>**

Inverse to the lower incomplete gamma function with respect to *x*.

Given an input y between 0 and 1, returns x such that $y = P(a, x)$. Here P is the regularized lower incomplete gamma function; see *gammainc*. This is well-defined because the lower incomplete gamma function is monotonic as can be seen from its definition in [dlmf].

Parameters

a [array_like] Positive parameter
y [array_like] Parameter between 0 and 1, inclusive

Returns

scalar or ndarray
Values of the inverse of the lower incomplete gamma function

See also:

gammainc

regularized lower incomplete gamma function

gammaincc

regularized upper incomplete gamma function

gammainccinv

inverse of the regualizred upper incomplete gamma function with respect to *x*

References

[dlmf]

Examples

```
>>> import scipy.special as sc
```

It starts at 0 and monotonically increases to infinity.

```
>>> sc.gammaincinv(0.5, [0, 0.1 ,0.5, 1])
array([0.        , 0.00789539, 0.22746821,        inf])
```

It inverts the lower incomplete gamma function.

```
>>> a, x = 0.5, [0, 0.1, 0.5, 1]
>>> sc.gammainc(a, sc.gammaincinv(a, x))
array([0. , 0.1, 0.5, 1. ])
```

```
>>> a, x = 0.5, [0, 10, 25]
>>> sc.gammaincinv(a, sc.gammainc(a, x))
array([ 0.        , 10.        , 25.00001465])
```

scipy.special.gammaincc

scipy.special.**gammaincc**(a, x) **= <ufunc 'gammaincc'>**

Regularized upper incomplete gamma function.

It is defined as

$$Q(a, x) = \frac{1}{\Gamma(a)} \int_x^\infty t^{a-1} e^{-t} dt$$

for $a > 0$ and $x \geq 0$. See [dlmf] for details.

Parameters

a [array_like] Positive parameter
x [array_like] Nonnegative argument

Returns

scalar or ndarray
Values of the upper incomplete gamma function

See also:

gammainc

regularized lower incomplete gamma function

gammaincinv

inverse of the regularized lower incomplete gamma function with respect to x

gammainccinv

inverse to of the regularized upper incomplete gamma function with respect to x

Notes

The function satisfies the relation `gammainc(a, x) + gammaincc(a, x) = 1` where *gammainc* is the regularized lower incomplete gamma function.

The implementation largely follows that of [boost].

References

[dlmf], [boost]

Examples

```
>>> import scipy.special as sc
```

It is the survival function of the gamma distribution, so it starts at 1 and monotonically decreases to 0.

```
>>> sc.gammaincc(0.5, [0, 1, 10, 100, 1000])
array([1.00000000e+00, 1.57299207e-01, 7.74421643e-06, 2.08848758e-45,
       0.00000000e+00])
```

It is equal to one minus the lower incomplete gamma function.

```
>>> a, x = 0.5, 0.4
>>> sc.gammaincc(a, x)
0.37109336952269756
>>> 1 - sc.gammainc(a, x)
0.37109336952269756
```

scipy.special.gammainccinv

scipy.special.**gammainccinv**(*a*, *y*) **= <ufunc 'gammainccinv'>**

Inverse of the upper incomplete gamma function with respect to x

Given an input y between 0 and 1, returns x such that $y = Q(a, x)$. Here Q is the upper incomplete gamma function; see *gammaincc*. This is well-defined because the upper incomplete gamma function is monotonic as can be seen from its definition in [dlmf].

Parameters

a [array_like] Positive parameter
y [array_like] Argument between 0 and 1, inclusive

Returns

scalar or ndarray
Values of the inverse of the upper incomplete gamma function

See also:

gammaincc

regularized upper incomplete gamma function

gammainc

regularized lower incomplete gamma function

gammaincinv

inverse of the regularized lower incomplete gamma function with respect to x

References

[dlmf]

Examples

```
>>> import scipy.special as sc
```

It starts at infinity and monotonically decreases to 0.

```
>>> sc.gammainccinv(0.5, [0, 0.1, 0.5, 1])
array([       inf, 1.35277173, 0.22746821, 0.        ])
```

It inverts the upper incomplete gamma function.

```
>>> a, x = 0.5, [0, 0.1, 0.5, 1]
>>> sc.gammaincc(a, sc.gammainccinv(a, x))
array([0. , 0.1, 0.5, 1. ])
```

```
>>> a, x = 0.5, [0, 10, 50]
>>> sc.gammainccinv(a, sc.gammaincc(a, x))
array([ 0., 10., 50.])
```

scipy.special.beta

scipy.special.**beta**(*a*, *b*, *out=None*) **= <ufunc 'beta'>**

Beta function.

This function is defined in [1] as

$$B(a, b) = \int_0^1 t^{a-1}(1-t)^{b-1}dt = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)},$$

where Γ is the gamma function.

Parameters

a, b [array-like] Real-valued arguments
out [ndarray, optional] Optional output array for the function result

Returns

scalar or ndarray
Value of the beta function

See also:

gamma

the gamma function

betainc

the incomplete beta function

betaln

the natural logarithm of the absolute value of the beta function

References

[1]

Examples

```
>>> import scipy.special as sc
```

The beta function relates to the gamma function by the definition given above:

```
>>> sc.beta(2, 3)
0.08333333333333333
>>> sc.gamma(2)*sc.gamma(3)/sc.gamma(2 + 3)
0.08333333333333333
```

As this relationship demonstrates, the beta function is symmetric:

```
>>> sc.beta(1.7, 2.4)
0.16567527689031739
>>> sc.beta(2.4, 1.7)
0.16567527689031739
```

This function satisfies $B(1, b) = 1/b$:

```
>>> sc.beta(1, 4)
0.25
```

scipy.special.betaln

scipy.special.**betaln**(*a*, *b*) **= <ufunc 'betaln'>**

Natural logarithm of absolute value of beta function.

Computes `ln(abs(beta(a, b)))`.

scipy.special.betainc

scipy.special.**betainc**(*a*, *b*, *x*, *out=None*) **= <ufunc 'betainc'>**

Incomplete beta function.

Computes the incomplete beta function, defined as [1]:

$$I_x(a,b) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} \int_0^x t^{a-1}(1-t)^{b-1}dt,$$

for $0 \leq x \leq 1$.

Parameters

a, b	[array-like] Positive, real-valued parameters
x	[array-like] Real-valued such that $0 \leq x \leq 1$, the upper limit of integration
out	[ndarray, optional] Optional output array for the function values

Returns

array-like	Value of the incomplete beta function

See also:

beta

beta function

betaincinv

inverse of the incomplete beta function

Notes

The incomplete beta function is also sometimes defined without the *gamma* terms, in which case the above definition is the so-called regularized incomplete beta function. Under this definition, you can get the incomplete beta function by multiplying the result of the SciPy function by *beta*.

References

[1]

Examples

Let $B(a,b)$ be the *beta* function.

```
>>> import scipy.special as sc
```

The coefficient in terms of *gamma* is equal to $1/B(a,b)$. Also, when $x = 1$ the integral is equal to $B(a,b)$. Therefore, $I_{x=1}(a,b) = 1$ for any a,b.

```
>>> sc.betainc(0.2, 3.5, 1.0)
1.0
```

It satisfies $I_x(a,b) = x^a F(a, 1-b, a+1, x)/(aB(a,b))$, where F is the hypergeometric function *hyp2f1*:

```
>>> a, b, x = 1.4, 3.1, 0.5
>>> x**a * sc.hyp2f1(a, 1 - b, a + 1, x)/(a * sc.beta(a, b))
0.8148904036225295
>>> sc.betainc(a, b, x)
0.8148904036225296
```

This functions satisfies the relationship $I_x(a,b) = 1 - I_{1-x}(b,a)$:

```
>>> sc.betainc(2.2, 3.1, 0.4)
0.49339638807619446
>>> 1 - sc.betainc(3.1, 2.2, 1 - 0.4)
0.49339638807619446
```

scipy.special.betaincinv

scipy.special.**betaincinv**(*a*, *b*, *y*, *out=None*) **= <ufunc 'betaincinv'>**

Inverse of the incomplete beta function.

Computes x such that:

$$y = I_x(a,b) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} \int_0^x t^{a-1}(1-t)^{b-1}dt,$$

where I_x is the normalized incomplete beta function *betainc* and Γ is the *gamma* function [1].

Parameters

a, b	[array-like] Positive, real-valued parameters
y	[array-like] Real-valued input
out	[ndarray, optional] Optional output array for function values

Returns

array-like	Value of the inverse of the incomplete beta function

See also:

betainc

incomplete beta function

gamma

gamma function

References

[1]

Examples

```
>>> import scipy.special as sc
```

This function is the inverse of *betainc* for fixed values of a and b.

```
>>> a, b = 1.2, 3.1
>>> y = sc.betainc(a, b, 0.2)
>>> sc.betaincinv(a, b, y)
0.2
>>>
>>> a, b = 7.5, 0.4
>>> x = sc.betaincinv(a, b, 0.5)
>>> sc.betainc(a, b, x)
0.5
```

scipy.special.psi

scipy.special.**psi**(*z*, *out=None*) **= <ufunc 'psi'>**

The digamma function.

The logarithmic derivative of the gamma function evaluated at `z`.

Parameters

z	[array_like] Real or complex argument.
out	[ndarray, optional] Array for the computed values of `psi`.

Returns

digamma	[ndarray] Computed values of `psi`.

Notes

For large values not close to the negative real axis, `psi` is computed using the asymptotic series (5.11.2) from [1]. For small arguments not close to the negative real axis, the recurrence relation (5.5.2) from [1] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis, the reflection formula (5.5.4) from [1] is used first. Note that `psi` has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [2], so the function should maintain full accuracy around the origin.

References

[1], [2]

Examples

```
>>> from scipy.special import psi
>>> z = 3 + 4j
>>> psi(z)
(1.55035981733341+1.0105022091860445j)
```

Verify psi(z) = psi(z + 1) - 1/z:

```
>>> psi(z + 1) - 1/z
(1.55035981733341+1.0105022091860445j)
```

scipy.special.rgamma

scipy.special.**rgamma**(*z*, *out=None*) **= <ufunc 'rgamma'>**

Reciprocal of the gamma function.

Defined as $1/\Gamma(z)$, where Γ is the gamma function. For more on the gamma function see *gamma*.

Parameters

z	[array_like] Real or complex valued input
out	[ndarray, optional] Optional output array for the function results

Returns

scalar or ndarray
Function results

See also:

gamma, **gammaln**, **loggamma**

Notes

The gamma function has no zeros and has simple poles at nonpositive integers, so *rgamma* is an entire function with zeros at the nonpositive integers. See the discussion in [dlmf] for more details.

References

[dlmf]

Examples

```
>>> import scipy.special as sc
```

It is the reciprocal of the gamma function.

```
>>> sc.rgamma([1, 2, 3, 4])
array([1.        , 1.        , 0.5       , 0.16666667])
>>> 1 / sc.gamma([1, 2, 3, 4])
array([1.        , 1.        , 0.5       , 0.16666667])
```

It is zero at nonpositive integers.

```
>>> sc.rgamma([0, -1, -2, -3])
array([0., 0., 0., 0.])
```

It rapidly underflows to zero along the positive real axis.

```
>>> sc.rgamma([10, 100, 179])
array([2.75573192e-006, 1.07151029e-156, 0.00000000e+000])
```

scipy.special.polygamma

scipy.special.**polygamma**(*n*, *x*)

Polygamma functions.

Defined as $\psi^{(n)}(x)$ where ψ is the *digamma* function. See [dlmf] for details.

Parameters

n	[array_like] The order of the derivative of the digamma function; must be integral
x	[array_like] Real valued input

Returns

ndarray	Function results

See also:

digamma

References

[dlmf]

Examples

```
>>> from scipy import special
>>> x = [2, 3, 25.5]
>>> special.polygamma(1, x)
array([ 0.64493407,  0.39493407,  0.03999467])
>>> special.polygamma(0, x) == special.psi(x)
array([ True,  True,  True], dtype=bool)
```

scipy.special.multigammaln

scipy.special.**multigammaln**(*a*, *d*)

Returns the log of multivariate gamma, also sometimes called the generalized gamma.

Parameters

a	[ndarray] The multivariate gamma is computed for each item of a.
d	[int] The dimension of the space of integration.

Returns

res [ndarray] The values of the log multivariate gamma at the given points a.

Notes

The formal definition of the multivariate gamma of dimension d for a real a is

$$\Gamma_d(a) = \int_{A>0} e^{-tr(A)} |A|^{a-(d+1)/2} dA$$

with the condition $a > (d-1)/2$, and $A > 0$ being the set of all the positive definite matrices of dimension d. Note that a is a scalar: the integrand only is multivariate, the argument is not (the function is defined over a subset of the real set).

This can be proven to be equal to the much friendlier equation

$$\Gamma_d(a) = \pi^{d(d-1)/4} \prod_{i=1}^{d} \Gamma(a - (i-1)/2).$$

References

R. J. Muirhead, Aspects of multivariate statistical theory (Wiley Series in probability and mathematical statistics).

scipy.special.digamma

scipy.special.**digamma**(*z*, *out=None*) **= <ufunc 'psi'>**

The digamma function.

The logarithmic derivative of the gamma function evaluated at `z`.

Parameters

z [array_like] Real or complex argument.
out [ndarray, optional] Array for the computed values of `psi`.

Returns

digamma [ndarray] Computed values of `psi`.

Notes

For large values not close to the negative real axis, `psi` is computed using the asymptotic series (5.11.2) from [1]. For small arguments not close to the negative real axis, the recurrence relation (5.5.2) from [1] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis, the reflection formula (5.5.4) from [1] is used first. Note that `psi` has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [2], so the function should maintain full accuracy around the origin.

References

[1], [2]

Examples

```
>>> from scipy.special import psi
>>> z = 3 + 4j
>>> psi(z)
(1.55035981733341+1.0105022091860445j)
```

Verify psi(z) = psi(z + 1) - 1/z:

```
>>> psi(z + 1) - 1/z
(1.55035981733341+1.0105022091860445j)
```

scipy.special.poch

scipy.special.**poch**(*z*, *m*) **= <ufunc 'poch'>**

Pochhammer symbol.

The Pochhammer symbol (rising factorial) is defined as

$$(z)_m = \frac{\Gamma(z+m)}{\Gamma(z)}$$

For positive integer *m* it reads

$$(z)_m = z(z+1)...(z+m-1)$$

See [dlmf] for more details.

Parameters

z, m [array_like] Real-valued arguments.

Returns

scalar or ndarray
The value of the function.

References

[dlmf]

Examples

```
>>> import scipy.special as sc
```

It is 1 when m is 0.

```
>>> sc.poch([1, 2, 3, 4], 0)
array([1., 1., 1., 1.])
```

For z equal to 1 it reduces to the factorial function.

```
>>> sc.poch(1, 5)
120.0
>>> 1 * 2 * 3 * 4 * 5
120
```

It can be expressed in terms of the gamma function.

```
>>> z, m = 3.7, 2.1
>>> sc.poch(z, m)
20.529581933776953
>>> sc.gamma(z + m) / sc.gamma(z)
20.52958193377696
```

Error function and Fresnel integrals

erf(z)	Returns the error function of complex argument.
erfc(x[, out])	Complementary error function, `1 - erf(x)`.
erfcx(x[, out])	Scaled complementary error function, `exp(x**2) * erfc(x)`.
erfi(z[, out])	Imaginary error function, `-i erf(i z)`.
erfinv(x, /[, out, where, casting, order, …])	Inverse of the error function.
erfcinv(x, /[, out, where, casting, order, …])	Inverse of the complementary error function.
wofz(z)	Faddeeva function
dawsn(x)	Dawson's integral.
fresnel(z[, out])	Fresnel integrals.
fresnel_zeros(nt)	Compute nt complex zeros of sine and cosine Fresnel integrals S(z) and C(z).
modfresnelp(x)	Modified Fresnel positive integrals
modfresnelm(x)	Modified Fresnel negative integrals
voigt_profile(x, sigma, gamma[, out])	Voigt profile.

scipy.special.erf

scipy.special.**erf**(*z*) **= <ufunc 'erf'>**

Returns the error function of complex argument.

It is defined as `2/sqrt(pi)*integral(exp(-t**2), t=0..z)`.

Parameters

x [ndarray] Input array.

Returns

res [ndarray] The values of the error function at the given points *x*.

See also:

erfc, **erfinv**, **erfcinv**, **wofz**, **erfcx**, **erfi**

Notes

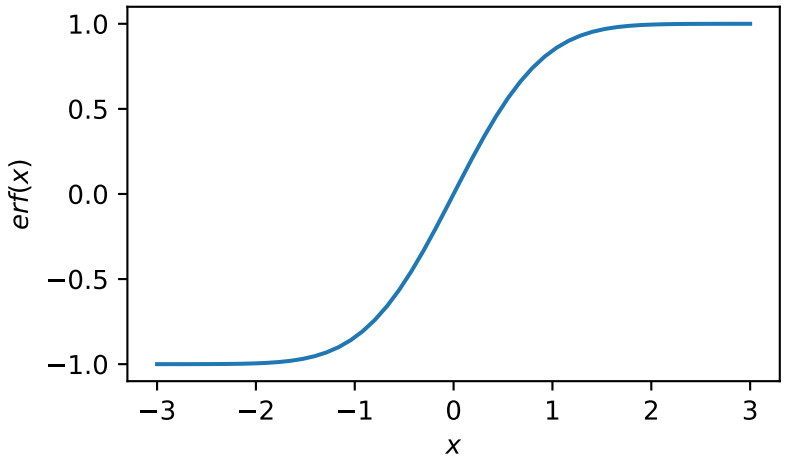
The cumulative of the unit normal distribution is given by `Phi(z) = 1/2[1 + erf(z/sqrt(2))]`.

References

[1], [2], [3]

Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erf(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$erf(x)$')
>>> plt.show()
```



scipy.special.erfc

`scipy.special.`**`erfc`**(*x*, *out=None*) **`= <ufunc 'erfc'>`**

Complementary error function, `1 - erf(x)`.

Parameters

x [array_like] Real or complex valued argument
out [ndarray, optional] Optional output array for the function results

Returns

scalar or ndarray
Values of the complementary error function

See also:

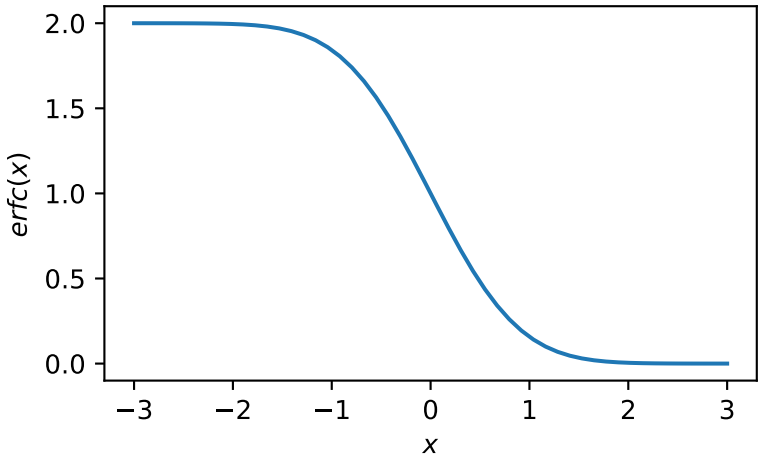
erf, **erfi**, **erfcx**, **dawsn**, **wofz**

References

[1]

Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfc(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$erfc(x)$')
>>> plt.show()
```



scipy.special.erfcx

scipy.special.**erfcx**(*x*, *out=None*) **= <ufunc 'erfcx'>**

Scaled complementary error function, `exp(x**2) * erfc(x)`.

Parameters

x [array_like] Real or complex valued argument
out [ndarray, optional] Optional output array for the function results

Returns

scalar or ndarray
Values of the scaled complementary error function

See also:

erf, **erfc**, **erfi**, **dawsn**, **wofz**

Notes

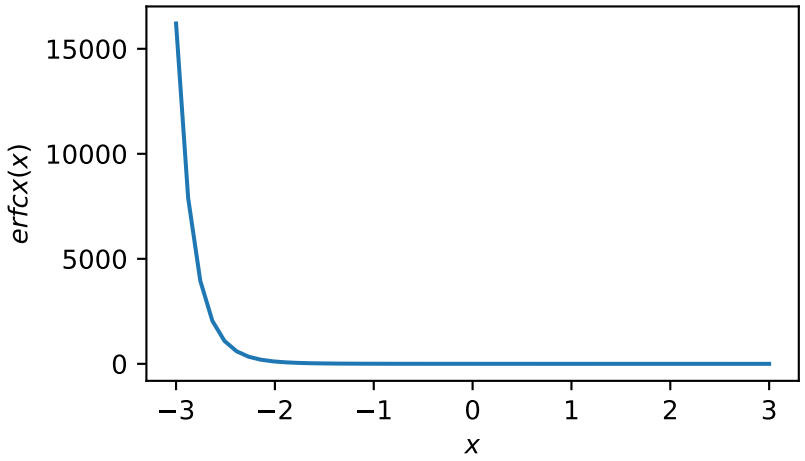
New in version 0.12.0.

References

[1]

Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfcx(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$erfcx(x)$')
>>> plt.show()
```



scipy.special.erfi

scipy.special.**erfi**(*z*, *out=None*) **= <ufunc 'erfi'>**

Imaginary error function, `-i erf(i z)`.

Parameters

z	[array_like] Real or complex valued argument
out	[ndarray, optional] Optional output array for the function results

Returns

scalar or ndarray
Values of the imaginary error function

See also:

erf, **erfc**, **erfcx**, **dawsn**, **wofz**

Notes

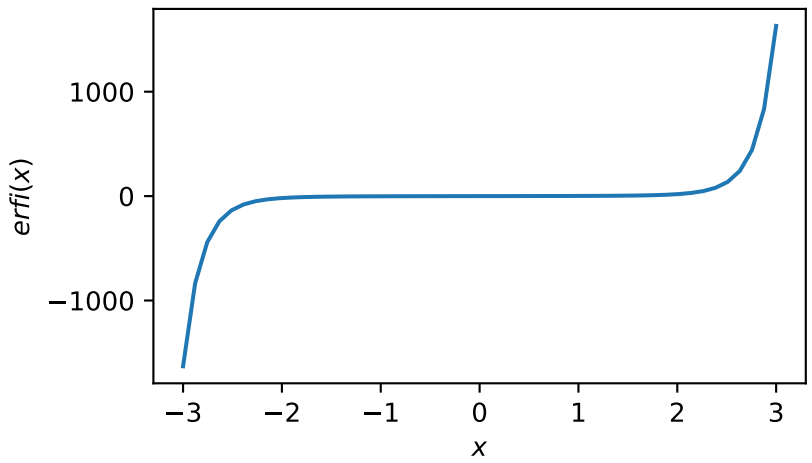
New in version 0.12.0.

References

[1]

Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfi(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$erfi(x)$')
>>> plt.show()
```



scipy.special.erfinv

scipy.special.**erfinv**(*x*, */*, *out=None*, ***, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True*[, *signature*, *extobj*]) **= <ufunc 'erfinv'>**

Inverse of the error function.

Computes the inverse of the error function.
In the complex domain, there is no unique complex number w satisfying erf(w)=z. This indicates a true inverse function would have multi-value. When the domain restricts to the real, -1 < x < 1, there is a unique real number satisfying erf(erfinv(x)) = x.

Parameters

y [ndarray] Argument at which to evaluate. Domain: [-1, 1]

Returns

erfinv [ndarray] The inverse of erf of y, element-wise)

See also:

erf

Error function of a complex argument

erfc

Complementary error function, `1 - erf(x)`

erfcinv

Inverse of the complementary error function

Examples

1) evaluating a float number

```
>>> from scipy import special
>>> special.erfinv(0.5)
0.4769362762044698
```

2) evaluating an ndarray

```
>>> from scipy import special
>>> y = np.linspace(-1.0, 1.0, num=10)
>>> special.erfinv(y)
array([       -inf, -0.86312307, -0.5407314 , -0.30457019, -0.0987901 ,
        0.0987901 ,  0.30457019,  0.5407314 ,  0.86312307,         inf])
```

scipy.special.erfcinv

scipy.special.**erfcinv**(*x*, */*, *out=None*, ***, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True*[, *signature*, *extobj*]) **= <ufunc 'erfcinv'>**

Inverse of the complementary error function.

Computes the inverse of the complementary error function.
In the complex domain, there is no unique complex number w satisfying erfc(w)=z. This indicates a true inverse function would have multi-value. When the domain restricts to the real, 0 < x < 2, there is a unique real number satisfying erfc(erfcinv(x)) = erfcinv(erfc(x)).
It is related to inverse of the error function by erfcinv(1-x) = erfinv(x)

Parameters

y [ndarray] Argument at which to evaluate. Domain: [0, 2]

Returns

erfcinv [ndarray] The inverse of erfc of y, element-wise

See also:

erf

Error function of a complex argument

erfc

Complementary error function, `1 - erf(x)`

erfinv

Inverse of the error function

Examples

1) evaluating a float number

```
>>> from scipy import special
>>> special.erfcinv(0.5)
0.4769362762044698
```

2) evaluating an ndarray

```
>>> from scipy import special
>>> y = np.linspace(0.0, 2.0, num=11)
>>> special.erfcinv(y)
array([        inf,  0.9061938 ,  0.59511608,  0.37080716,  0.17914345,
       -0.        , -0.17914345, -0.37080716, -0.59511608, -0.9061938 ,
              -inf])
```

scipy.special.wofz

scipy.special.**wofz**(*z*) = <ufunc 'wofz'>

Faddeeva function

Returns the value of the Faddeeva function for complex argument:

```
exp(-z**2) * erfc(-i*z)
```

See also:

dawsn, **erf**, **erfc**, **erfcx**, **erfi**

References

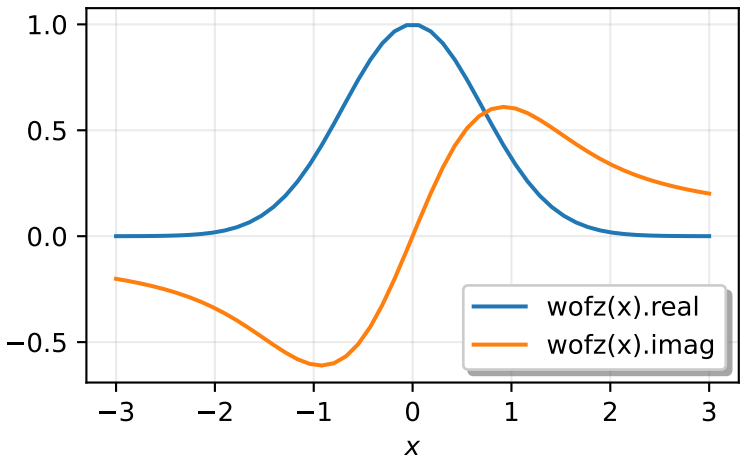
[1]

Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-3, 3)
>>> z = special.wofz(x)
```

```
>>> plt.plot(x, z.real, label='wofz(x).real')
>>> plt.plot(x, z.imag, label='wofz(x).imag')
>>> plt.xlabel('$x$')
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.grid(alpha=0.25)
>>> plt.show()
```



scipy.special.dawsn

scipy.special.**dawsn**(*x*) **= <ufunc 'dawsn'>**

Dawson's integral.

Computes:

```
exp(-x**2) * integral(exp(t**2), t=0..x).
```

See also:

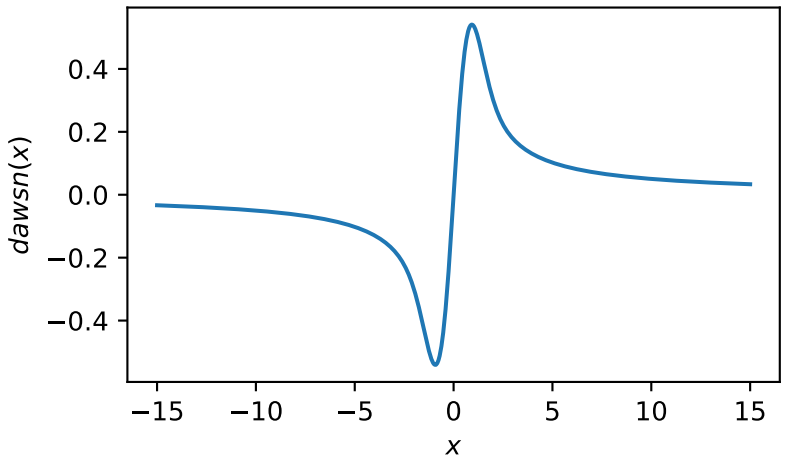
wofz, **erf**, **erfc**, **erfcx**, **erfi**

References

[1]

Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-15, 15, num=1000)
>>> plt.plot(x, special.dawsn(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$dawsn(x)$')
>>> plt.show()
```



scipy.special.fresnel

scipy.special.**fresnel**(*z*, *out=None*) **= <ufunc 'fresnel'>**

Fresnel integrals.

The Fresnel integrals are defined as

$$S(z) = \int_0^z \sin(\pi t^2/2)dt$$
$$C(z) = \int_0^z \cos(\pi t^2/2)dt.$$

See [dlmf] for details.

Parameters

z	[array_like] Real or complex valued argument
out	[2-tuple of ndarrays, optional] Optional output arrays for the function results

Returns

S, C	[2-tuple of scalar or ndarray] Values of the Fresnel integrals

See also:

fresnel_zeros

zeros of the Fresnel integrals

References

[dlmf]

Examples

```
>>> import scipy.special as sc
```

As z goes to infinity along the real axis, S and C converge to 0.5.

```
>>> S, C = sc.fresnel([0.1, 1, 10, 100, np.inf])
>>> S
array([0.00052359, 0.43825915, 0.46816998, 0.4968169 , 0.5       ])
>>> C
array([0.09999753, 0.7798934 , 0.49989869, 0.4999999 , 0.5       ])
```

They are related to the error function *erf*.

```
>>> z = np.array([1, 2, 3, 4])
>>> zeta = 0.5 * np.sqrt(np.pi) * (1 - 1j) * z
>>> S, C = sc.fresnel(z)
>>> C + 1j*S
array([0.7798934 +0.43825915j, 0.48825341+0.34341568j,
       0.60572079+0.496313j  , 0.49842603+0.42051575j])
>>> 0.5 * (1 + 1j) * sc.erf(zeta)
array([0.7798934 +0.43825915j, 0.48825341+0.34341568j,
       0.60572079+0.496313j  , 0.49842603+0.42051575j])
```

scipy.special.fresnel_zeros

scipy.special.**fresnel_zeros**(*nt*)
Compute nt complex zeros of sine and cosine Fresnel integrals S(z) and C(z).

References

[1]

scipy.special.modfresnelp

scipy.special.**modfresnelp**(*x*) **= <ufunc 'modfresnelp'>**
Modified Fresnel positive integrals

Returns

fp	Integral `F_+(x): integral(exp(1j*t*t), t=x..inf)`
kp	Integral `K_+(x): 1/sqrt(pi)*exp(-1j*(x*x+pi/4))*fp`

scipy.special.modfresnelm

scipy.special.**modfresnelm**(*x*) **= <ufunc 'modfresnelm'>**
Modified Fresnel negative integrals

Returns

fm	Integral `F_-(x): integral(exp(-1j*t*t), t=x..inf)`
km	Integral `K_-(x): 1/sqrt(pi)*exp(1j*(x*x+pi/4))*fp`

scipy.special.voigt_profile

scipy.special.**voigt_profile**(*x*, *sigma*, *gamma*, *out=None*) **= <ufunc 'voigt_profile'>**
Voigt profile.

The Voigt profile is a convolution of a 1-D Normal distribution with standard deviation `sigma` and a 1-D Cauchy distribution with half-width at half-maximum `gamma`.

If `sigma = 0`, PDF of Cauchy distribution is returned. Conversely, if `gamma = 0`, PDF of Normal distribution is returned. If `sigma = gamma = 0`, the return value is `Inf` for `x = 0`, and `0` for all other `x`.

Parameters

x	[array_like] Real argument
sigma	[array_like] The standard deviation of the Normal distribution part
gamma	[array_like] The half-width at half-maximum of the Cauchy distribution part
out	[ndarray, optional] Optional output array for the function values

Returns

scalar or ndarray
The Voigt profile at the given arguments

See also:

wofz

Faddeeva function

Notes

It can be expressed in terms of Faddeeva function

$$V(x;\sigma,\gamma) = \frac{Re[w(z)]}{\sigma\sqrt{2\pi}},$$

$$z = \frac{x+i\gamma}{\sqrt{2}\sigma}$$

where $w(z)$ is the Faddeeva function.

References

[1]

These are not universal functions:

erf_zeros(nt)	Compute the first nt zero in the first quadrant, ordered by absolute value.
fresnelc_zeros(nt)	Compute nt complex zeros of cosine Fresnel integral C(z).
fresnels_zeros(nt)	Compute nt complex zeros of sine Fresnel integral S(z).

scipy.special.erf_zeros

scipy.special.**erf_zeros**(*nt*)

Compute the first nt zero in the first quadrant, ordered by absolute value.

Zeros in the other quadrants can be obtained by using the symmetries erf(-z) = erf(z) and erf(conj(z)) = conj(erf(z)).

Parameters

nt [int] The number of zeros to compute

Returns

The locations of the zeros of erf
[ndarray (complex)] Complex values at which zeros of erf(z)

References

[1]

Examples

```
>>> from scipy import special
>>> special.erf_zeros(1)
array([1.45061616+1.880943j])
```

Check that erf is (close to) zero for the value returned by erf_zeros

```
>>> special.erf(special.erf_zeros(1))
array([4.95159469e-14-1.16407394e-16j])
```

scipy.special.fresnelc_zeros

scipy.special.**fresnelc_zeros**(*nt*)
Compute nt complex zeros of cosine Fresnel integral C(z).

References

[1]

scipy.special.fresnels_zeros

scipy.special.**fresnels_zeros**(*nt*)
Compute nt complex zeros of sine Fresnel integral S(z).

References

[1]

Legendre functions

lpmv(m, v, x)	Associated Legendre function of integer order and real degree.
sph_harm(m, n, theta, phi)	Compute spherical harmonics.

scipy.special.lpmv

scipy.special.**lpmv**(*m*, *v*, *x*) **= <ufunc 'lpmv'>**
Associated Legendre function of integer order and real degree.

Defined as

$$P_v^m = (-1)^m (1 - x^2)^{m/2} \frac{d^m}{dx^m} P_v(x)$$

where

$$P_v = \sum_{k=0}^{\infty} \frac{(-v)_k (v+1)_k}{(k!)^2} \left(\frac{1-x}{2}\right)^k$$

is the Legendre function of the first kind. Here $(\cdot)_k$ is the Pochhammer symbol; see *poch*.

Parameters

m [array_like] Order (int or float). If passed a float not equal to an integer the function returns NaN.
v [array_like] Degree (float).
x [array_like] Argument (float). Must have `|x| <= 1`.

Returns

pmv [ndarray] Value of the associated Legendre function.

See also:

lpmn

Compute the associated Legendre function for all orders `0, ..., m` and degrees `0, ..., n`.

clpmn

Compute the associated Legendre function at complex arguments.

Notes

Note that this implementation includes the Condon-Shortley phase.

References

[1]

scipy.special.sph_harm

scipy.special.**sph_harm**(*m*, *n*, *theta*, *phi*) **= <ufunc 'sph_harm'>**

Compute spherical harmonics.

The spherical harmonics are defined as

$$Y_n^m(\theta,\phi) = \sqrt{\frac{2n+1}{4\pi}\frac{(n-m)!}{(n+m)!}}e^{im\theta}P_n^m(\cos(\phi))$$

where P_n^m are the associated Legendre functions; see *lpmv*.

Parameters

m [array_like] Order of the harmonic (int); must have `|m| <= n`.
n [array_like] Degree of the harmonic (int); must have `n >= 0`. This is often denoted by `l` (lower case L) in descriptions of spherical harmonics.
theta [array_like] Azimuthal (longitudinal) coordinate; must be in `[0, 2*pi]`.
phi [array_like] Polar (colatitudinal) coordinate; must be in `[0, pi]`.

Returns

y_mn [complex float] The harmonic Y_n^m sampled at `theta` and `phi`.

Notes

There are different conventions for the meanings of the input arguments `theta` and `phi`. In SciPy `theta` is the azimuthal angle and `phi` is the polar angle. It is common to see the opposite convention, that is, `theta` as the polar angle and `phi` as the azimuthal angle.

Note that SciPy's spherical harmonics include the Condon-Shortley phase [2] because it is part of *lpmv*.

With SciPy's conventions, the first several spherical harmonics are

$$Y_0^0(\theta, \phi) = \frac{1}{2}\sqrt{\frac{1}{\pi}}$$
$$Y_1^{-1}(\theta, \phi) = \frac{1}{2}\sqrt{\frac{3}{2\pi}}e^{-i\theta}\sin(\phi)$$
$$Y_1^0(\theta, \phi) = \frac{1}{2}\sqrt{\frac{3}{\pi}}\cos(\phi)$$
$$Y_1^1(\theta, \phi) = -\frac{1}{2}\sqrt{\frac{3}{2\pi}}e^{i\theta}\sin(\phi).$$

References

[1], [2]

These are not universal functions:

clpmn(m, n, z[, type])	Associated Legendre function of the first kind for complex arguments.
lpn(n, z)	Legendre function of the first kind.
lqn(n, z)	Legendre function of the second kind.
lpmn(m, n, z)	Sequence of associated Legendre functions of the first kind.
lqmn(m, n, z)	Sequence of associated Legendre functions of the second kind.

scipy.special.clpmn

scipy.special.**clpmn**(*m*, *n*, *z*, *type=3*)

Associated Legendre function of the first kind for complex arguments.

Computes the associated Legendre function of the first kind of order m and degree n, `Pmn(z)` = $P_n^m(z)$, and its derivative, `Pmn'(z)`. Returns two arrays of size `(m+1, n+1)` containing `Pmn(z)` and `Pmn'(z)` for all orders from `0..m` and degrees from `0..n`.

Parameters

m	[int] `|m| <= n`; the order of the Legendre function.
n	[int] where `n >= 0`; the degree of the Legendre function. Often called `l` (lower case L) in descriptions of the associated Legendre function
z	[float or complex] Input value.
type	[int, optional] takes values 2 or 3 2: cut on the real axis `|x| > 1` 3: cut on the real axis `-1 < x < 1` (default)

Returns

Pmn_z [(m+1, n+1) array] Values for all orders `0..m` and degrees `0..n`
Pmn_d_z [(m+1, n+1) array] Derivatives for all orders `0..m` and degrees `0..n`

See also:

`lpmn`

associated Legendre functions of the first kind for real z

Notes

By default, i.e. for `type=3`, phase conventions are chosen according to [1] such that the function is analytic. The cut lies on the interval (-1, 1). Approaching the cut from above or below in general yields a phase factor with respect to Ferrer's function of the first kind (cf. *lpmn*).

For `type=2` a cut at `|x| > 1` is chosen. Approaching the real values on the interval (-1, 1) in the complex plane yields Ferrer's function of the first kind.

References

[1], [2]

scipy.special.lpn

`scipy.special.`**`lpn`**(*n*, *z*)
Legendre function of the first kind.

Compute sequence of Legendre functions of the first kind (polynomials), Pn(z) and derivatives for all degrees from 0 to n (inclusive).

See also special.legendre for polynomial class.

References

[1]

scipy.special.lqn

`scipy.special.`**`lqn`**(*n*, *z*)
Legendre function of the second kind.

Compute sequence of Legendre functions of the second kind, Qn(z) and derivatives for all degrees from 0 to n (inclusive).

References

[1]

scipy.special.lpmn

scipy.special.**lpmn**(*m*, *n*, *z*)

Sequence of associated Legendre functions of the first kind.

Computes the associated Legendre function of the first kind of order m and degree n, `Pmn(z)` = $P_n^m(z)$, and its derivative, `Pmn'(z)`. Returns two arrays of size `(m+1, n+1)` containing `Pmn(z)` and `Pmn'(z)` for all orders from `0..m` and degrees from `0..n`.

This function takes a real argument `z`. For complex arguments `z` use clpmn instead.

Parameters

m	[int] `|m| <= n`; the order of the Legendre function.
n	[int] where `n >= 0`; the degree of the Legendre function. Often called `l` (lower case L) in descriptions of the associated Legendre function
z	[float] Input value.

Returns

Pmn_z	[(m+1, n+1) array] Values for all orders 0..m and degrees 0..n
Pmn_d_z	[(m+1, n+1) array] Derivatives for all orders 0..m and degrees 0..n

See also:

clpmn

associated Legendre functions of the first kind for complex z

Notes

In the interval (-1, 1), Ferrer's function of the first kind is returned. The phase convention used for the intervals (1, inf) and (-inf, -1) is such that the result is always real.

References

[1], [2]

scipy.special.lqmn

scipy.special.**lqmn**(*m*, *n*, *z*)

Sequence of associated Legendre functions of the second kind.

Computes the associated Legendre function of the second kind of order m and degree n, `Qmn(z)` = $Q_n^m(z)$, and its derivative, `Qmn'(z)`. Returns two arrays of size `(m+1, n+1)` containing `Qmn(z)` and `Qmn'(z)` for all orders from `0..m` and degrees from `0..n`.

Parameters

m	[int] `|m| <= n`; the order of the Legendre function.
n	[int] where `n >= 0`; the degree of the Legendre function. Often called `l` (lower case L) in descriptions of the associated Legendre function

z [complex] Input value.

Returns

Qmn_z [(m+1, n+1) array] Values for all orders 0..m and degrees 0..n
Qmn_d_z [(m+1, n+1) array] Derivatives for all orders 0..m and degrees 0..n

Ellipsoidal harmonics

ellip_harm(h2, k2, n, p, s[, signm, signn])	Ellipsoidal harmonic functions E^p_n(l)
ellip_harm_2(h2, k2, n, p, s)	Ellipsoidal harmonic functions F^p_n(l)
ellip_normal(h2, k2, n, p)	Ellipsoidal harmonic normalization constants gamma^p_n

scipy.special.ellip_harm

scipy.special.**ellip_harm**(*h2*, *k2*, *n*, *p*, *s*, *signm=1*, *signn=1*)

Ellipsoidal harmonic functions E^p_n(l)

These are also known as Lame functions of the first kind, and are solutions to the Lame equation:

$$(s^2 - h^2)(s^2 - k^2)E''(s) + s(2s^2 - h^2 - k^2)E'(s) + (a - qs^2)E(s) = 0$$

where $q = (n+1)n$ and a is the eigenvalue (not returned) corresponding to the solutions.

Parameters

h2 [float] `h**2`
k2 [float] `k**2`; should be larger than `h**2`
n [int] Degree
s [float] Coordinate
p [int] Order, can range between [1,2n+1]
signm [{1, -1}, optional] Sign of prefactor of functions. Can be +/-1. See Notes.
signn [{1, -1}, optional] Sign of prefactor of functions. Can be +/-1. See Notes.

Returns

E [float] the harmonic $E^p_n(s)$

See also:

ellip_harm_2, **ellip_normal**

Notes

The geometric interpretation of the ellipsoidal functions is explained in [2], [3], [4]. The *signm* and *signn* arguments control the sign of prefactors for functions according to their type:

```
K : +1
L : signm
M : signn
N : signm*signn
```

New in version 0.15.0.

References

[1], [2], [3], [4]

Examples

```
>>> from scipy.special import ellip_harm
>>> w = ellip_harm(5,8,1,1,2.5)
>>> w
2.5
```

Check that the functions indeed are solutions to the Lame equation:

```
>>> from scipy.interpolate import UnivariateSpline
>>> def eigenvalue(f, df, ddf):
...     r = ((s**2 - h**2)*(s**2 - k**2)*ddf + s*(2*s**2 - h**2 -␣
↪k**2)*df - n*(n+1)*s**2*f)/f
...     return -r.mean(), r.std()
>>> s = np.linspace(0.1, 10, 200)
>>> k, h, n, p = 8.0, 2.2, 3, 2
>>> E = ellip_harm(h**2, k**2, n, p, s)
>>> E_spl = UnivariateSpline(s, E)
>>> a, a_err = eigenvalue(E_spl(s), E_spl(s,1), E_spl(s,2))
>>> a, a_err
(583.44366156701483, 6.4580890640310646e-11)
```

scipy.special.ellip_harm_2

scipy.special.**ellip_harm_2**(*h2*, *k2*, *n*, *p*, *s*)

Ellipsoidal harmonic functions F^p_n(l)

These are also known as Lame functions of the second kind, and are solutions to the Lame equation:

$$(s^2 - h^2)(s^2 - k^2)F''(s) + s(2s^2 - h^2 - k^2)F'(s) + (a - qs^2)F(s) = 0$$

where $q = (n + 1)n$ and a is the eigenvalue (not returned) corresponding to the solutions.

Parameters

h2 [float] `h**2`

k2 [float] `k**2`; should be larger than `h**2`

n	[int] Degree.
p	[int] Order, can range between [1,2n+1].
s	[float] Coordinate

Returns

F	[float] The harmonic $F_n^p(s)$

See also:

ellip_harm, **ellip_normal**

Notes

Lame functions of the second kind are related to the functions of the first kind:

$$F_n^p(s) = (2n+1)E_n^p(s)\int_0^{1/s} \frac{du}{(E_n^p(1/u))^2\sqrt{(1-u^2k^2)(1-u^2h^2)}}$$

New in version 0.15.0.

Examples

```
>>> from scipy.special import ellip_harm_2
>>> w = ellip_harm_2(5,8,2,1,10)
>>> w
0.00108056853382
```

scipy.special.ellip_normal

scipy.special.**ellip_normal**(*h2*, *k2*, *n*, *p*)

Ellipsoidal harmonic normalization constants gamma^p_n

The normalization constant is defined as

$$\gamma_n^p = 8\int_0^h dx \int_h^k dy \frac{(y^2-x^2)(E_n^p(y)E_n^p(x))^2}{\sqrt((k^2-y^2)(y^2-h^2)(h^2-x^2)(k^2-x^2)}$$

Parameters

h2	[float] `h**2`
k2	[float] `k**2`; should be larger than `h**2`
n	[int] Degree.
p	[int] Order, can range between [1,2n+1].

Returns

gamma	[float] The normalization constant γ_n^p

See also:

ellip_harm, **ellip_harm_2**

Notes

New in version 0.15.0.

Examples

```
>>> from scipy.special import ellip_normal
>>> w = ellip_normal(5,8,3,7)
>>> w
1723.38796997
```

Orthogonal polynomials

The following functions evaluate values of orthogonal polynomials:

assoc_laguerre(x, n[, k])	Compute the generalized (associated) Laguerre polynomial of degree n and order k.
eval_legendre(n, x[, out])	Evaluate Legendre polynomial at a point.
eval_chebyt(n, x[, out])	Evaluate Chebyshev polynomial of the first kind at a point.
eval_chebyu(n, x[, out])	Evaluate Chebyshev polynomial of the second kind at a point.
eval_chebyc(n, x[, out])	Evaluate Chebyshev polynomial of the first kind on [-2, 2] at a point.
eval_chebys(n, x[, out])	Evaluate Chebyshev polynomial of the second kind on [-2, 2] at a point.
eval_jacobi(n, alpha, beta, x[, out])	Evaluate Jacobi polynomial at a point.
eval_laguerre(n, x[, out])	Evaluate Laguerre polynomial at a point.
eval_genlaguerre(n, alpha, x[, out])	Evaluate generalized Laguerre polynomial at a point.
eval_hermite(n, x[, out])	Evaluate physicist's Hermite polynomial at a point.
eval_hermitenorm(n, x[, out])	Evaluate probabilist's (normalized) Hermite polynomial at a point.
eval_gegenbauer(n, alpha, x[, out])	Evaluate Gegenbauer polynomial at a point.
eval_sh_legendre(n, x[, out])	Evaluate shifted Legendre polynomial at a point.
eval_sh_chebyt(n, x[, out])	Evaluate shifted Chebyshev polynomial of the first kind at a point.
eval_sh_chebyu(n, x[, out])	Evaluate shifted Chebyshev polynomial of the second kind at a point.
eval_sh_jacobi(n, p, q, x[, out])	Evaluate shifted Jacobi polynomial at a point.

scipy.special.assoc_laguerre

scipy.special.**assoc_laguerre**(*x*, *n*, *k=0.0*)

Compute the generalized (associated) Laguerre polynomial of degree n and order k.

The polynomial $L_n^{(k)}(x)$ is orthogonal over `[0, inf)`, with weighting function `exp(-x) * x**k` with `k > -1`.

Notes

assoc_laguerre is a simple wrapper around *eval_genlaguerre*, with reversed argument order `(x, n, k=0.0) --> (n, k, x)`.

scipy.special.eval_legendre

scipy.special.**eval_legendre**(*n*, *x*, *out=None*) **= <ufunc 'eval_legendre'>**

Evaluate Legendre polynomial at a point.

The Legendre polynomials can be defined via the Gauss hypergeometric function ${}_2F_1$ as

$$P_n(x) = {}_2F_1(-n, n+1; 1; (1-x)/2).$$

When n is an integer the result is a polynomial of degree n. See 22.5.49 in [AS] for details.

Parameters

n	[array_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
x	[array_like] Points at which to evaluate the Legendre polynomial

Returns

P	[ndarray] Values of the Legendre polynomial

See also:

[AS]

Examples

```
>>> from scipy.special import eval_legendre
```

Evaluate the zero-order Legendre polynomial at x = 0

```
>>> eval_legendre(0, 0)
1.0
```

Evaluate the first-order Legendre polynomial between -1 and 1

```
>>> X = np.linspace(-1, 1, 5)  # Domain of Legendre polynomials
>>> eval_legendre(1, X)
array([-1. , -0.5,  0. ,  0.5,  1. ])
```

Evaluate Legendre polynomials of order 0 through 4 at x = 0

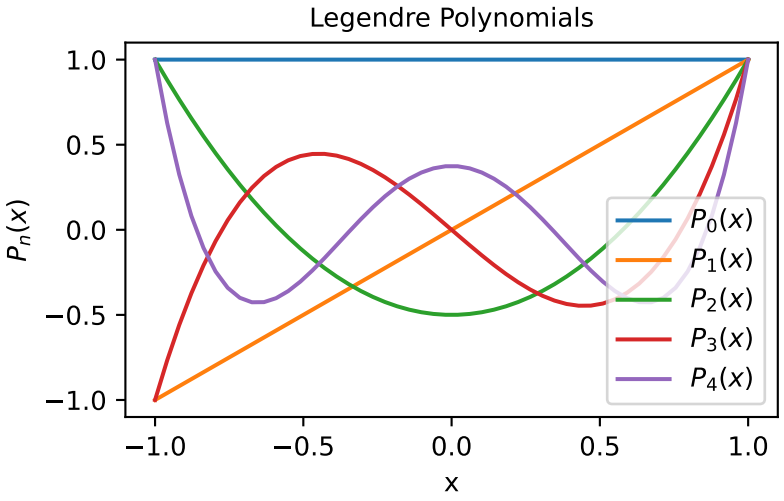
```
>>> N = range(0, 5)
>>> eval_legendre(N, 0)
array([ 1.   ,  0.   , -0.5  ,  0.   ,  0.375])
```

Plot Legendre polynomials of order 0 through 4

```
>>> X = np.linspace(-1, 1)
```

```
>>> import matplotlib.pyplot as plt
>>> for n in range(0, 5):
...     y = eval_legendre(n, X)
...     plt.plot(X, y, label=r'$P_{}(x)$'.format(n))
```

```
>>> plt.title("Legendre Polynomials")
>>> plt.xlabel("x")
>>> plt.ylabel(r'$P_n(x)$')
>>> plt.legend(loc='lower right')
>>> plt.show()
```



scipy.special.eval_chebyt

scipy.special.**eval_chebyt**(*n*, *x*, *out=None*) **= <ufunc 'eval_chebyt'>**

Evaluate Chebyshev polynomial of the first kind at a point.

The Chebyshev polynomials of the first kind can be defined via the Gauss hypergeometric function ${}_2F_1$ as

$$T_n(x) = {}_2F_1(n, -n; 1/2; (1-x)/2).$$

When n is an integer the result is a polynomial of degree n. See 22.5.47 in [AS] for details.

Parameters

n	[array_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
x	[array_like] Points at which to evaluate the Chebyshev polynomial

Returns

T	[ndarray] Values of the Chebyshev polynomial

scipy.special.eval_chebyu

scipy.special.**eval_chebyu**(*n*, *x*, *out=None*) **= <ufunc 'eval_chebyu'>**

Evaluate Chebyshev polynomial of the second kind at a point.

The Chebyshev polynomials of the second kind can be defined via the Gauss hypergeometric function ${}_2F_1$ as

$$U_n(x) = (n+1){}_2F_1(-n, n+2; 3/2; (1-x)/2).$$

When n is an integer the result is a polynomial of degree n. See 22.5.48 in [AS] for details.

Parameters

n [array_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.

x [array_like] Points at which to evaluate the Chebyshev polynomial

Returns

U [ndarray] Values of the Chebyshev polynomial

See also:

roots_chebyu

roots and quadrature weights of Chebyshev polynomials of the second kind

chebyu

Chebyshev polynomial object

eval_chebyt

evaluate Chebyshev polynomials of the first kind

```

scipy.special.eval_jacobi

scipy.special.**eval_jacobi**(*n*, *alpha*, *beta*, *x*, *out=None*) **= <ufunc 'eval_jacobi'>**

Evaluate Jacobi polynomial at a point.

The Jacobi polynomials can be defined via the Gauss hypergeometric function ${}_2F_1$ as

$$P_n^{(\alpha,\beta)}(x) = \frac{(\alpha+1)_n}{\Gamma(n+1)} {}_2F_1(-n, 1+\alpha+\beta+n; \alpha+1; (1-z)/2)$$

where $(\cdot)_n$ is the Pochhammer symbol; see *poch*. When n is an integer the result is a polynomial of degree n. See 22.5.42 in [AS] for details.

Parameters

n	[array_like] Degree of the polynomial. If not an integer the result is determined via the relation to the Gauss hypergeometric function.
alpha	[array_like] Parameter
beta	[array_like] Parameter
x	[array_like] Points at which to evaluate the polynomial

Returns

scipy.special.roots_legendre

scipy.special.**roots_legendre**(*n*, *mu=False*)

Gauss-Legendre quadrature.

Compute the sample points and weights for Gauss-Legendre quadrature. The sample points are the roots of the nth degree Legendre polynomial $P_n(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[-1, 1]$ with weight function $w(x) = 1.0$. See 2.2.10 in [AS] for more details.

Parameters

n	[int] quadrature order
mu	[bool, optional] If True, return the sum of the weights, optional.

Returns

x	[ndarray] Sample points
w	[ndarray] Weights
mu	[float] Sum of the weights

See also:

roots_hermitenorm

Notes

For small n up to 150 a modified version of the Golub-Welsch algorithm is used. Nodes are computed from the eigenvalue problem and improved by one step of a Newton iteration. The weights are computed from the well-known analytical formula.

For n larger than 150 an optimal asymptotic algorithm is applied which computes nodes and weights in a numerically stable manner. The algorithm has linear runtime making computation for very large n (several thousand or more) feasible.

scipy.integrate.quadrature

scipy.integrate.fixed_quad

References

[AS]

scipy.special.roots_sh_jacobi

scipy.special.**roots_sh_jacobi**(*n*, *p1*, *q1*, *mu=False*)

Gauss-Jacobi (shifted) quadrature.

Compute the sample points and weights for Gauss-Jacobi (shifted) quadrature. The sample points are the roots of the nth degree shifted Jacobi polynomial, $G_n^{p,q}(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[0, 1]$ with weight function $w(x) = (1 - x)^{p-q} x^{q-1}$. See 22.2.2 in [AS] for details.

Parameters

n	[int] quadrature order
p1	[float] (p1 - q1) must be > -1
q1	[float] q1 must be > 0
mu	[bool, optional] If True, return the sum of the weights, optional.

Returns

x	[ndarray] Sample points
w	[ndarray] Weights
mu	[float] Sum of the weights

See also:

scipy.integrate.quadrature

scipy.integrate.fixed_quad

References

[AS]

The functions below, in turn, return the polynomial coefficients in `orthopoly1d` objects, which function similarly as `numpy.poly1d`. The `orthopoly1d` class also has an attribute `weights`, which returns the roots, weights, and total weights for the appropriate form of Gaussian quadrature. These are returned in an `n x 3` array with roots in the first column, weights in the second column, and total weights in the final column. Note that `orthopoly1d` objects are converted to `poly1d` when doing arithmetic, and lose information of the original orthogonal polynomial.

legendre(n[, monic])	Legendre polynomial.
chebyt(n[, monic])	Chebyshev polynomial of the first kind.
chebyu(n[, monic])	Chebyshev polynomial of the second kind.
chebyc(n[, monic])	Chebyshev polynomial of the first kind on $[-2, 2]$.
chebys(n[, monic])	Chebyshev polynomial of the second kind on $[-2, 2]$.
jacobi(n, alpha, beta[, monic])	Jacobi polynomial.
laguerre(n[, monic])	Laguerre polynomial.
genlaguerre(n, alpha[, monic])	Generalized (associated) Laguerre polynomial.
hermite(n[, monic])	Physicist's Hermite polynomial.
hermitenorm(n[, monic])	Normalized (probabilist's) Hermite polynomial.
gegenbauer(n, alpha[, monic])	Gegenbauer (ultraspherical) polynomial.
sh_legendre(n[, monic])	Shifted Legendre polynomial.
sh_chebyt(n[, monic])	Shifted Chebyshev polynomial of the first kind.
sh_chebyu(n[, monic])	Shifted Chebyshev polynomial of the second kind.
sh_jacobi(n, p, q[, monic])	Shifted Jacobi polynomial.

scipy.special.legendre

scipy.special.**legendre**(*n*, *monic=False*)

Legendre polynomial.

Defined to be the solution of

$$\frac{d}{dx}\left[(1-x^2)\frac{d}{dx}P_n(x)\right] + n(n+1)P_n(x) = 0;$$

$P_n(x)$ is a polynomial of degree n.

Parameters

n	[int] Degree of the polynomial.
monic	[bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

Returns

P	[orthopoly1d] Legendre polynomial.

Notes

The polynomials P_n are orthogonal over $[-1, 1]$ with weight function 1.

Examples

Generate the 3rd-order Legendre polynomial 1/2*(5x^3 + 0x^2 - 3x + 0):

```
>>> from scipy.special import legendre
>>> legendre(3)
poly1d([ 2.5,  0. , -1.5,  0. ])
```

scipy.special.chebyt

scipy.special.**chebyt**(*n*, *monic=False*)

Chebyshev polynomial of the first kind.

Defined to be the solution of

$$(1 - x^2)\frac{d^2}{dx^2}T_n - x\frac{d}{dx}T_n + n^2 T_n = 0;$$

T_n is a polynomial of degree n.

Parameters

n	[int] Degree of the polynomial.
monic	[bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

Returns

T	[orthopoly1d] Chebyshev polynomial of the first kind.

See also:

chebyu

Chebyshev polynomial of the second kind.

Notes

The polynomials T_n are orthogonal over $[-1, 1]$ with weight function $(1 - x^2)^{-1/2}$.

scipy.special.chebyu

scipy.special.**chebyu**(*n*, *monic=False*)

Chebyshev polynomial of the second kind.

Defined to be the solution of

$$(1 - x^2)\frac{d^2}{dx^2}U_n - 3x\frac{d}{dx}U_n + n(n+2)U_n = 0;$$

U_n is a polynomial of degree n.

Parameters

n [int] Degree of the polynomial.
monic [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

Returns

U [orthopoly1d] Chebyshev polynomial of the second kind.

See also:

`chebyt`

Chebyshev polynomial of the first kind.

Notes

The polynomials U_n are orthogonal over $[-1, 1]$ with weight function $(1 - x^2)^{1/2}$.

scipy.special.chebyc

`scipy.special.`**`chebyc`**(*n*, *monic=False*)

Chebyshev polynomial of the first kind on $[-2, 2]$.

Defined as $C_n(x) = 2T_n(x/2)$, where T_n is the nth Chebychev polynomial of the first kind.

Parameters

n [int] Degree of the polynomial.
monic [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

Returns

C [orthopoly1d] Chebyshev polynomial of the first kind on $[-2, 2]$.

See also:

`chebyt`

Chebyshev polynomial of the first kind.

Notes

The polynomials $C_n(x)$ are orthogonal over $[-2, 2]$ with weight function $1/\sqrt{1 - (x/2)^2}$.

References

[1]

scipy.special.chebys

scipy.special.**chebys**(*n*, *monic=False*)

Chebyshev polynomial of the second kind on $[-2, 2]$.

Defined as $S_n(x) = U_n(x/2)$ where U_n is the nth Chebychev polynomial of the second kind.

Parameters

n	[int] Degree of the polynomial.
monic	[bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

Returns

S	[orthopoly1d] Chebyshev polynomial of the second kind on $[-2, 2]$.

See also:

chebyu

Chebyshev polynomial of the second kind

Notes

The polynomials $S_n(x)$ are orthogonal over $[-2, 2]$ with weight function $\sqrt{1 - (x/2)}^2$.

References

[1]

scipy.special.jacobi

scipy.special.**jacobi**(*n*, *alpha*, *beta*, *monic=False*)

Jacobi polynomial.

Defined to be the solution of

$$(1 - x^2)\frac{d^2}{dx^2}P_n^{(\alpha,\beta)} + (\beta - \alpha - (\alpha + \beta + 2)x)\frac{d}{dx}P_n^{(\alpha,\beta)} + n(n + \alpha + \beta + 1)P_n^{(\alpha,\beta)} = 0$$

for $\alpha, \beta > -1$; $P_n^{(\alpha,\beta)}$ is a polynomial of degree n.

Parameters

n	[int] Degree of the polynomial.
alpha	[float] Parameter, must be greater than -1.
beta	[float] Parameter, must be greater than -1.
monic	[bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

Returns

P	[orthopoly1d] Jacobi polynomial.

Notes

For fixed α, β, the polynomials $P_n^{(\alpha,\beta)}$ are orthogonal over $[-1, 1]$ with weight function $(1-x)^\alpha(1+x)^\beta$.

scipy.special.laguerre

`scipy.special.`**`laguerre`**(*n*, *monic=False*)

Laguerre polynomial.

Defined to be the solution of

$$x\frac{d^2}{dx^2}L_n + (1-x)\frac{d}{dx}L_n + nL_n = 0;$$

L_n is a polynomial of degree n.

Parameters

n	[int] Degree of the polynomial.
monic	[bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

Returns

L	[orthopoly1d] Laguerre Polynomial.

Notes

The polynomials L_n are orthogonal over $[0, \infty)$ with weight function e^{-x}.

scipy.special.genlaguerre

`scipy.special.`**`genlaguerre`**(*n*, *alpha*, *monic=False*)

Generalized (associated) Laguerre polynomial.

Defined to be the solution of

$$x\frac{d^2}{dx^2}L_n^{(\alpha)} + (\alpha+1-x)\frac{d}{dx}L_n^{(\alpha)} + nL_n^{(\alpha)} = 0,$$

where $\alpha > -1$; $L_n^{(\alpha)}$ is a polynomial of degree n.

Parameters

n	[int] Degree of the polynomial.
alpha	[float] Parameter, must be greater than -1.
monic	[bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

Returns

L	[orthopoly1d] Generalized Laguerre polynomial.

See also:

`laguerre`

Laguerre polynomial.

Notes

For fixed α, the polynomials $L_n^{(\alpha)}$ are orthogonal over $[0, \infty)$ with weight function $e^{-x}x^{\alpha}$.

The Laguerre polynomials are the special case where $\alpha = 0$.

scipy.special.hermite

scipy.special.**hermite**(*n*, *monic=False*)

Physicist's Hermite polynomial.

Defined by

$$H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2};$$

H_n is a polynomial of degree n.

Parameters

n	[int] Degree of the polynomial.
monic	[bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

Returns

H	[orthopoly1d] Hermite polynomial.

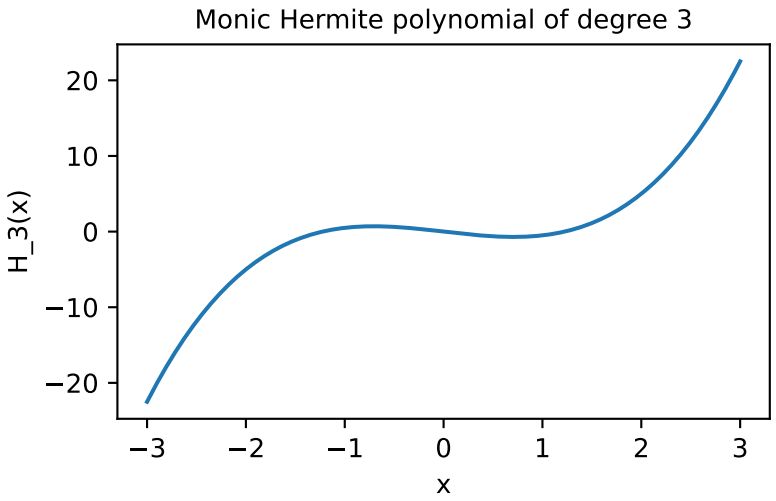
Notes

The polynomials H_n are orthogonal over $(-\infty, \infty)$ with weight function e^{-x^2}.

Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> import numpy as np
```

```
>>> p_monic = special.hermite(3, monic=True)
>>> p_monic
poly1d([ 1. ,  0. , -1.5,  0. ])
>>> p_monic(1)
-0.49999999999999983
>>> x = np.linspace(-3, 3, 400)
>>> y = p_monic(x)
>>> plt.plot(x, y)
>>> plt.title("Monic Hermite polynomial of degree 3")
>>> plt.xlabel("x")
>>> plt.ylabel("H_3(x)")
>>> plt.show()
```



scipy.special.hermitenorm

scipy.special.**hermitenorm**(*n*, *monic=False*)

Normalized (probabilist's) Hermite polynomial.

Defined by

$$He_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} e^{-x^2/2};$$

He_n is a polynomial of degree n.

Parameters

n	[int] Degree of the polynomial.
monic	[bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

Returns

He	[orthopoly1d] Hermite polynomial.

Notes

The polynomials He_n are orthogonal over $(-\infty, \infty)$ with weight function $e^{-x^2/2}$.

scipy.special.gegenbauer

scipy.special.**gegenbauer**(*n*, *alpha*, *monic=False*)

Gegenbauer (ultraspherical) polynomial.

Defined to be the solution of

$$(1-x^2)\frac{d^2}{dx^2}C_n^{(\alpha)} - (2\alpha+1)x\frac{d}{dx}C_n^{(\alpha)} + n(n+2\alpha)C_n^{(\alpha)} = 0$$

for $\alpha > -1/2$; $C_n^{(\alpha)}$ is a polynomial of degree n.

Parameters

n	[int] Degree of the polynomial.
alpha	[float] Parameter, must be greater than -0.5.
monic	[bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

Returns

C	[orthopoly1d] Gegenbauer polynomial.

Notes

The polynomials $C_n^{(\alpha)}$ are orthogonal over $[-1, 1]$ with weight function $(1 - x^2)^{(\alpha - 1/2)}$.

Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
```

We can initialize a variable `p` as a Gegenbauer polynomial using the *`gegenbauer`* function and evaluate at a point `x = 1`.

```
>>> p = special.gegenbauer(3, 0.5, monic=False)
>>> p
poly1d([ 2.5,  0. , -1.5,  0. ])
>>> p(1)
1.0
```

To evaluate `p` at various points `x` in the interval `(-3, 3)`, simply pass an array `x` to `p` as follows:

```
>>> x = np.linspace(-3, 3, 400)
>>> y = p(x)
```

We can then visualize `x, y` using `matplotlib.pyplot`.

```
>>> fig, ax = plt.subplots()
>>> ax.plot(x, y)
>>> ax.set_title("Gegenbauer (ultraspherical) polynomial of degree 3")
>>> ax.set_xlabel("x")
>>> ax.set_ylabel("G_3(x)")
>>> plt.show()
```

scipy.special.sh_legendre

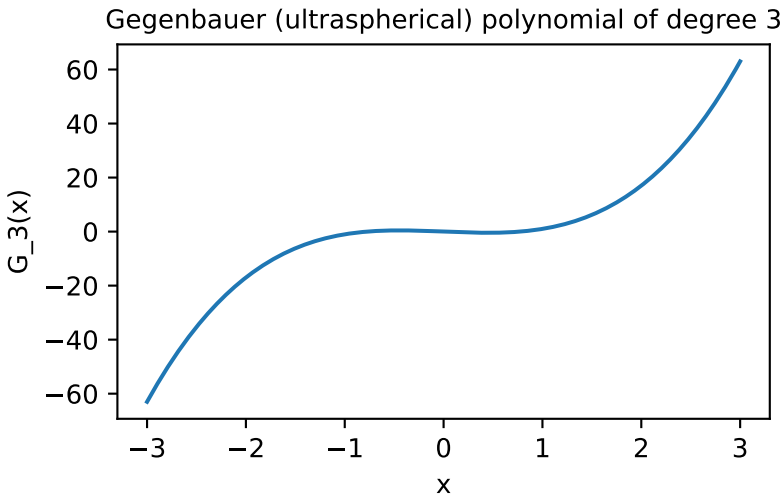
`scipy.special.`**`sh_legendre`**(*n*, *monic=False*)

Shifted Legendre polynomial.

Defined as $P_n^*(x) = P_n(2x - 1)$ for P_n the nth Legendre polynomial.

Parameters

n	[int] Degree of the polynomial.
monic	[bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.



Returns

P [orthopoly1d] Shifted Legendre polynomial.

Notes

The polynomials P_n^* are orthogonal over $[0, 1]$ with weight function 1.

scipy.special.sh_chebyt

`scipy.special.`**`sh_chebyt`**(*n*, *monic=False*)

Shifted Chebyshev polynomial of the first kind.

Defined as $T_n^*(x) = T_n(2x - 1)$ for T_n the nth Chebyshev polynomial of the first kind.

Parameters

n [int] Degree of the polynomial.

monic [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

Returns

T [orthopoly1d] Shifted Chebyshev polynomial of the first kind.

Notes

The polynomials T_n^* are orthogonal over $[0, 1]$ with weight function $(x - x^2)^{-1/2}$.

scipy.special.sh_chebyu

scipy.special.**sh_chebyu**(*n*, *monic=False*)

Shifted Chebyshev polynomial of the second kind.

Defined as $U_n^*(x) = U_n(2x-1)$ for U_n the nth Chebyshev polynomial of the second kind.

Parameters

n	[int] Degree of the polynomial.
monic	[bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

Returns

U	[orthopoly1d] Shifted Chebyshev polynomial of the second kind.

Notes

The polynomials U_n^* are orthogonal over $[0, 1]$ with weight function $(x - x^2)^{1/2}$.

scipy.special.sh_jacobi

scipy.special.**sh_jacobi**(*n*, *p*, *q*, *monic=False*)

Shifted Jacobi polynomial.

Defined by

$$G_n^{(p,q)}(x) = \binom{2n+p-1}{n}^{-1} P_n^{(p-q,q-1)}(2x-1),$$

where $P_n^{(\cdot,\cdot)}$ is the nth Jacobi polynomial.

Parameters

n	[int] Degree of the polynomial.
p	[float] Parameter, must have $p > q - 1$.
q	[float] Parameter, must be greater than 0.
monic	[bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

Returns

G	[orthopoly1d] Shifted Jacobi polynomial.

Notes

For fixed p, q, the polynomials $G_n^{(p,q)}$ are orthogonal over $[0, 1]$ with weight function $(1-x)^{p-q}x^{q-1}$.

Warning: Computing values of high-order polynomials (around `order > 20`) using polynomial coefficients is numerically unstable. To evaluate polynomial values, the `eval_*` functions should be used instead.

Hypergeometric functions

hyp2f1(a, b, c, z)	Gauss hypergeometric function 2F1(a, b; c; z)
hyp1f1(a, b, x[, out])	Confluent hypergeometric function 1F1.
hyperu(a, b, x[, out])	Confluent hypergeometric function U
hyp0f1(v, z[, out])	Confluent hypergeometric limit function 0F1.

scipy.special.hyp2f1

scipy.special.**hyp2f1**(*a*, *b*, *c*, *z*) **= <ufunc 'hyp2f1'>**

Gauss hypergeometric function 2F1(a, b; c; z)

Parameters

a, b, c [array_like] Arguments, should be real-valued.
z [array_like] Argument, real or complex.

Returns

hyp2f1 [scalar or ndarray] The values of the gaussian hypergeometric function.

See also:

hyp0f1

confluent hypergeometric limit function.

hyp1f1

Kummer's (confluent hypergeometric) function.

Notes

This function is defined for $|z| < 1$ as

$$\mathrm{hyp2f1}(a, b, c, z) = \sum_{n=0}^{\infty} \frac{(a)_n (b)_n}{(c)_n} \frac{z^n}{n!},$$

and defined on the rest of the complex z-plane by analytic continuation [1]. Here $(\cdot)_n$ is the Pochhammer symbol; see *poch*. When n is an integer the result is a polynomial of degree n.

The implementation for complex values of z is described in [2].

References

[1], [2], [3]

Examples

```
>>> import scipy.special as sc
```

It has poles when *c* is a negative integer.

```
>>> sc.hyp2f1(1, 1, -2, 1)
inf
```

It is a polynomial when *a* or *b* is a negative integer.

```
>>> a, b, c = -1, 1, 1.5
>>> z = np.linspace(0, 1, 5)
>>> sc.hyp2f1(a, b, c, z)
array([1.        , 0.83333333, 0.66666667, 0.5       , 0.33333333])
>>> 1 + a * b * z / c
array([1.        , 0.83333333, 0.66666667, 0.5       , 0.33333333])
```

It is symmetric in *a* and *b*.

```
>>> a = np.linspace(0, 1, 5)
>>> b = np.linspace(0, 1, 5)
>>> sc.hyp2f1(a, b, 1, 0.5)
array([1.        , 1.03997334, 1.1803406 , 1.47074441, 2.        ])
>>> sc.hyp2f1(b, a, 1, 0.5)
array([1.        , 1.03997334, 1.1803406 , 1.47074441, 2.        ])
```

It contains many other functions as special cases.

```
>>> z = 0.5
>>> sc.hyp2f1(1, 1, 2, z)
1.3862943611198901
>>> -np.log(1 - z) / z
1.3862943611198906
```

```
>>> sc.hyp2f1(0.5, 1, 1.5, z**2)
1.098612288668109
>>> np.log((1 + z) / (1 - z)) / (2 * z)
1.0986122886681098
```

```
>>> sc.hyp2f1(0.5, 1, 1.5, -z**2)
0.9272952180016117
>>> np.arctan(z) / z
0.9272952180016123
```

scipy.special.hyp1f1

scipy.special.**hyp1f1**(*a*, *b*, *x*, *out=None*) **= <ufunc 'hyp1f1'>**

Confluent hypergeometric function 1F1.

The confluent hypergeometric function is defined by the series

$$ {}_1F_1(a; b; x) = \sum_{k=0}^{\infty} \frac{(a)_k}{(b)_k k!} x^k. $$

See [dlmf] for more details. Here $(\cdot)_k$ is the Pochhammer symbol; see *poch*.

Parameters

a, b	[array_like] Real parameters
x	[array_like] Real or complex argument
out	[ndarray, optional] Optional output array for the function results

Returns

scalar or ndarray
Values of the confluent hypergeometric function

See also:

hyperu

another confluent hypergeometric function

hyp0f1

confluent hypergeometric limit function

hyp2f1

Gaussian hypergeometric function

References

[dlmf]

Examples

```
>>> import scipy.special as sc
```

It is one when *x* is zero:

```
>>> sc.hyp1f1(0.5, 0.5, 0)
1.0
```

It is singular when *b* is a nonpositive integer.

```
>>> sc.hyp1f1(0.5, -1, 0)
inf
```

It is a polynomial when *a* is a nonpositive integer.

```
>>> a, b, x = -1, 0.5, np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.hyp1f1(a, b, x)
array([-1., -3., -5., -7.])
>>> 1 + (a / b) * x
array([-1., -3., -5., -7.])
```

It reduces to the exponential function when $a = b$.

```
>>> sc.hyp1f1(2, 2, [1, 2, 3, 4])
array([ 2.71828183,  7.3890561 , 20.08553692, 54.59815003])
>>> np.exp([1, 2, 3, 4])
array([ 2.71828183,  7.3890561 , 20.08553692, 54.59815003])
```

scipy.special.hyperu

scipy.special.**hyperu**(*a*, *b*, *x*, *out=None*) **= <ufunc 'hyperu'>**

Confluent hypergeometric function U

It is defined as the solution to the equation

$$x\frac{d^2w}{dx^2} + (b - x)\frac{dw}{dx} - aw = 0$$

which satisfies the property

$$U(a, b, x) \sim x^{-a}$$

as $x \to \infty$. See [dlmf] for more details.

Parameters

a, b	[array_like] Real-valued parameters
x	[array_like] Real-valued argument
out	[ndarray] Optional output array for the function values

Returns

scalar or ndarray
Values of U

References

[dlmf]

Examples

```
>>> import scipy.special as sc
```

It has a branch cut along the negative x axis.

```
>>> x = np.linspace(-0.1, -10, 5)
>>> sc.hyperu(1, 1, x)
array([nan, nan, nan, nan, nan])
```

It approaches zero as x goes to infinity.

```
>>> x = np.array([1, 10, 100])
>>> sc.hyperu(1, 1, x)
array([0.59634736, 0.09156333, 0.00990194])
```

It satisfies Kummer's transformation.

```
>>> a, b, x = 2, 1, 1
>>> sc.hyperu(a, b, x)
0.1926947246463881
>>> x**(1 - b) * sc.hyperu(a - b + 1, 2 - b, x)
0.1926947246463881
```

scipy.special.hyp0f1

scipy.special.**hyp0f1**(*v*, *z*, *out=None*) **= <ufunc 'hyp0f1'>**

Confluent hypergeometric limit function 0F1.

Parameters

v	[array_like] Real-valued parameter
z	[array_like] Real- or complex-valued argument
out	[ndarray, optional] Optional output array for the function results

Returns

scalar or ndarray
The confluent hypergeometric limit function

Notes

This function is defined as:

$$ {}_0F_1(v, z) = \sum_{k=0}^{\infty} \frac{z^k}{(v)_k k!}. $$

It's also the limit as $q \to \infty$ of ${}_1F_1(q; v; z/q)$, and satisfies the differential equation $f''(z) + vf'(z) = f(z)$. See [1] for more information.

References

[1]

Examples

```
>>> import scipy.special as sc
```

It is one when z is zero.

```
>>> sc.hyp0f1(1, 0)
1.0
```

It is the limit of the confluent hypergeometric function as q goes to infinity.

```
>>> q = np.array([1, 10, 100, 1000])
>>> v = 1
>>> z = 1
>>> sc.hyp1f1(q, v, z / q)
array([2.71828183, 2.31481985, 2.28303778, 2.27992985])
>>> sc.hyp0f1(v, z)
2.2795853023360673
```

It is related to Bessel functions.

```
>>> n = 1
>>> x = np.linspace(0, 1, 5)
>>> sc.jv(n, x)
array([0.        , 0.12402598, 0.24226846, 0.3492436 , 0.44005059])
>>> (0.5 * x)**n / sc.factorial(n) * sc.hyp0f1(n + 1, -0.25 * x**2)
array([0.        , 0.12402598, 0.24226846, 0.3492436 , 0.44005059])
```

Parabolic cylinder functions

pbdv(v, x)	Parabolic cylinder function D
pbvv(v, x)	Parabolic cylinder function V
pbwa(a, x)	Parabolic cylinder function W.

scipy.special.pbdv

scipy.special.**pbdv**(*v*, *x*) **= <ufunc 'pbdv'>**

Parabolic cylinder function D

Returns (d, dp) the parabolic cylinder function Dv(x) in d and the derivative, Dv'(x) in dp.

Returns

d	Value of the function
dp	Value of the derivative vs x

scipy.special.pbvv

scipy.special.**pbvv**(*v*, *x*) **= <ufunc 'pbvv'>**
Parabolic cylinder function V

Returns the parabolic cylinder function Vv(x) in v and the derivative, Vv'(x) in vp.

Returns

v	Value of the function
vp	Value of the derivative vs x

scipy.special.pbwa

scipy.special.**pbwa**(*a*, *x*) **= <ufunc 'pbwa'>**
Parabolic cylinder function W.

The function is a particular solution to the differential equation

$$y'' + \left(\frac{1}{4}x^2 - a\right) y = 0,$$

for a full definition see section 12.14 in [1].

Parameters

a	[array_like] Real parameter
x	[array_like] Real argument

Returns

w	[scalar or ndarray] Value of the function
wp	[scalar or ndarray] Value of the derivative in x

Notes

The function is a wrapper for a Fortran routine by Zhang and Jin [2]. The implementation is accurate only for `|a|, |x| < 5` and returns NaN outside that range.

[1], [2]

These are not universal functions:

pbdv_seq(v, x)	Parabolic cylinder functions Dv(x) and derivatives.
pbvv_seq(v, x)	Parabolic cylinder functions Vv(x) and derivatives.
pbdn_seq(n, z)	Parabolic cylinder functions Dn(z) and derivatives.

scipy.special.pbdv_seq

scipy.special.**pbdv_seq**(*v*, *x*)
Parabolic cylinder functions Dv(x) and derivatives.

Parameters

v	[float] Order of the parabolic cylinder function
x	[float] Value at which to evaluate the function and derivatives

Returns

dv	[ndarray] Values of D_vi(x), for vi=v-int(v), vi=1+v-int(v), …, vi=v.
dp	[ndarray] Derivatives D_vi'(x), for vi=v-int(v), vi=1+v-int(v), …, vi=v.

References

[1]

scipy.special.pbvv_seq

scipy.special.**pbvv_seq**(*v*, *x*)
Parabolic cylinder functions Vv(x) and derivatives.

Parameters

v	[float] Order of the parabolic cylinder function
x	[float] Value at which to evaluate the function and derivatives

Returns

dv	[ndarray] Values of V_vi(x), for vi=v-int(v), vi=1+v-int(v), …, vi=v.
dp	[ndarray] Derivatives V_vi'(x), for vi=v-int(v), vi=1+v-int(v), …, vi=v.

References

[1]

scipy.special.pbdn_seq

scipy.special.**pbdn_seq**(*n*, *z*)
Parabolic cylinder functions Dn(z) and derivatives.

Parameters

n	[int] Order of the parabolic cylinder function
z	[complex] Value at which to evaluate the function and derivatives

Returns

dv	[ndarray] Values of D_i(z), for i=0, …, i=n.
dp	[ndarray] Derivatives D_i'(z), for i=0, …, i=n.

References

[1]

Mathieu and related functions

mathieu_a(m, q)	Characteristic value of even Mathieu functions
mathieu_b(m, q)	Characteristic value of odd Mathieu functions

scipy.special.mathieu_a

scipy.special.**mathieu_a**(*m*, *q*) **= <ufunc 'mathieu_a'>**
Characteristic value of even Mathieu functions

Returns the characteristic value for the even solution, `ce_m(z, q)`, of Mathieu's equation.

scipy.special.mathieu_b

scipy.special.**mathieu_b**(*m*, *q*) **= <ufunc 'mathieu_b'>**
Characteristic value of odd Mathieu functions

Returns the characteristic value for the odd solution, `se_m(z, q)`, of Mathieu's equation.

These are not universal functions:

mathieu_even_coef(m, q)	Fourier coefficients for even Mathieu and modified Mathieu functions.
mathieu_odd_coef(m, q)	Fourier coefficients for even Mathieu and modified Mathieu functions.

scipy.special.mathieu_even_coef

scipy.special.**mathieu_even_coef**(*m*, *q*)
Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the even solutions of the Mathieu differential equation are of the form

$$\mathrm{ce}_{2n}(z,q) = \sum_{k=0}^{\infty} A_{(2n)}^{(2k)} \cos 2kz$$

$$\mathrm{ce}_{2n+1}(z,q) = \sum_{k=0}^{\infty} A_{(2n+1)}^{(2k+1)} \cos(2k+1)z$$

This function returns the coefficients $A_{(2n)}^{(2k)}$ for even input m=2n, and the coefficients $A_{(2n+1)}^{(2k+1)}$ for odd input m=2n+1.

Parameters

m [int] Order of Mathieu functions. Must be non-negative.
q [float (>=0)] Parameter of Mathieu functions. Must be non-negative.

Returns

Ak [ndarray] Even or odd Fourier coefficients, corresponding to even or odd m.

References

[1], [2]

scipy.special.mathieu_odd_coef

scipy.special.**mathieu_odd_coef**(*m*, *q*)

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the odd solutions of the Mathieu differential equation are of the form

$$\mathrm{se}_{2n+1}(z,q) = \sum_{k=0}^{\infty} B_{(2n+1)}^{(2k+1)} \sin(2k+1)z$$

$$\mathrm{se}_{2n+2}(z,q) = \sum_{k=0}^{\infty} B_{(2n+2)}^{(2k+2)} \sin(2k+2)z$$

This function returns the coefficients $B_{(2n+2)}^{(2k+2)}$ for even input m=2n+2, and the coefficients $B_{(2n+1)}^{(2k+1)}$ for odd input m=2n+1.

Parameters

m	[int] Order of Mathieu functions. Must be non-negative.
q	[float (>=0)] Parameter of Mathieu functions. Must be non-negative.

Returns

Bk	[ndarray] Even or odd Fourier coefficients, corresponding to even or odd m.

References

[1]

The following return both function and first derivative:

mathieu_cem(m, q, x)	Even Mathieu function and its derivative
mathieu_sem(m, q, x)	Odd Mathieu function and its derivative
mathieu_modcem1(m, q, x)	Even modified Mathieu function of the first kind and its derivative
mathieu_modcem2(m, q, x)	Even modified Mathieu function of the second kind and its derivative
mathieu_modsem1(m, q, x)	Odd modified Mathieu function of the first kind and its derivative
mathieu_modsem2(m, q, x)	Odd modified Mathieu function of the second kind and its derivative

scipy.special.mathieu_cem

scipy.special.**mathieu_cem**(*m*, *q*, *x*) **= <ufunc 'mathieu_cem'>**

Even Mathieu function and its derivative

Returns the even Mathieu function, `ce_m(x, q)`, of order *m* and parameter *q* evaluated at *x* (given in degrees). Also returns the derivative with respect to *x* of ce_m(x, q)

Parameters

m	Order of the function
q	Parameter of the function
x	Argument of the function, *given in degrees, not radians*

Returns

y	Value of the function
yp	Value of the derivative vs x

scipy.special.mathieu_sem

scipy.special.**mathieu_sem**(*m*, *q*, *x*) **= <ufunc 'mathieu_sem'>**

Odd Mathieu function and its derivative

Returns the odd Mathieu function, se_m(x, q), of order *m* and parameter *q* evaluated at *x* (given in degrees). Also returns the derivative with respect to *x* of se_m(x, q).

Parameters

m	Order of the function
q	Parameter of the function
x	Argument of the function, *given in degrees, not radians*.

Returns

y	Value of the function
yp	Value of the derivative vs x

scipy.special.mathieu_modcem1

scipy.special.**mathieu_modcem1**(*m*, *q*, *x*) **= <ufunc 'mathieu_modcem1'>**

Even modified Mathieu function of the first kind and its derivative

Evaluates the even modified Mathieu function of the first kind, `Mc1m(x, q)`, and its derivative at *x* for order *m* and parameter *q*.

Returns

y	Value of the function
yp	Value of the derivative vs x

scipy.special.mathieu_modcem2

scipy.special.**mathieu_modcem2**(*m*, *q*, *x*) **= <ufunc 'mathieu_modcem2'>**

Even modified Mathieu function of the second kind and its derivative

Evaluates the even modified Mathieu function of the second kind, Mc2m(x, q), and its derivative at *x* (given in degrees) for order *m* and parameter *q*.

Returns

y	Value of the function
yp	Value of the derivative vs x

scipy.special.mathieu_modsem1

scipy.special.**mathieu_modsem1**(*m*, *q*, *x*) **= <ufunc 'mathieu_modsem1'>**

Odd modified Mathieu function of the first kind and its derivative

Evaluates the odd modified Mathieu function of the first kind, Ms1m(x, q), and its derivative at *x* (given in degrees) for order *m* and parameter *q*.

Returns

y	Value of the function
yp	Value of the derivative vs x

scipy.special.mathieu_modsem2

scipy.special.**mathieu_modsem2**(*m*, *q*, *x*) **= <ufunc 'mathieu_modsem2'>**

Odd modified Mathieu function of the second kind and its derivative

Evaluates the odd modified Mathieu function of the second kind, Ms2m(x, q), and its derivative at *x* (given in degrees) for order *m* and parameter q.

Returns

y	Value of the function
yp	Value of the derivative vs x

Spheroidal wave functions

pro_ang1(m, n, c, x)	Prolate spheroidal angular function of the first kind and its derivative
pro_rad1(m, n, c, x)	Prolate spheroidal radial function of the first kind and its derivative
pro_rad2(m, n, c, x)	Prolate spheroidal radial function of the second kind and its derivative
obl_ang1(m, n, c, x)	Oblate spheroidal angular function of the first kind and its derivative
obl_rad1(m, n, c, x)	Oblate spheroidal radial function of the first kind and its derivative
obl_rad2(m, n, c, x)	Oblate spheroidal radial function of the second kind and its derivative.
pro_cv(m, n, c)	Characteristic value of prolate spheroidal function
obl_cv(m, n, c)	Characteristic value of oblate spheroidal function

continues on next page

Table 248 – continued from previous page

pro_cv_seq(m, n, c)	Characteristic values for prolate spheroidal wave functions.
obl_cv_seq(m, n, c)	Characteristic values for oblate spheroidal wave functions.

scipy.special.pro_ang1

scipy.special.**pro_ang1**(*m*, *n*, *c*, *x*) **= <ufunc 'pro_ang1'>**

Prolate spheroidal angular function of the first kind and its derivative

Computes the prolate spheroidal angular function of the first kind and its derivative (with respect to *x*) for mode parameters m>=0 and n>=m, spheroidal parameter *c* and `|x| < 1.0`.

Returns

s	Value of the function
sp	Value of the derivative vs x

scipy.special.pro_rad1

scipy.special.**pro_rad1**(*m*, *n*, *c*, *x*) **= <ufunc 'pro_rad1'>**

Prolate spheroidal radial function of the first kind and its derivative

Computes the prolate spheroidal radial function of the first kind and its derivative (with respect to *x*) for mode parameters m>=0 and n>=m, spheroidal parameter *c* and `|x| < 1.0`.

Returns

s	Value of the function
sp	Value of the derivative vs x

scipy.special.pro_rad2

scipy.special.**pro_rad2**(*m*, *n*, *c*, *x*) **= <ufunc 'pro_rad2'>**

Prolate spheroidal radial function of the second kind and its derivative

Computes the prolate spheroidal radial function of the second kind and its derivative (with respect to *x*) for mode parameters m>=0 and n>=m, spheroidal parameter *c* and `|x| < 1.0`.

Returns

s	Value of the function
sp	Value of the derivative vs x

scipy.special.obl_ang1

scipy.special.**obl_ang1**(*m*, *n*, *c*, *x*) **= <ufunc 'obl_ang1'>**

Oblate spheroidal angular function of the first kind and its derivative

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to *x*) for mode parameters m>=0 and n>=m, spheroidal parameter *c* and `|x| < 1.0`.

Returns

s	Value of the function
sp	Value of the derivative vs x

scipy.special.obl_rad1

scipy.special.**obl_rad1**(*m*, *n*, *c*, *x*) **= <ufunc 'obl_rad1'>**

Oblate spheroidal radial function of the first kind and its derivative

Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to *x*) for mode parameters m>=0 and n>=m, spheroidal parameter *c* and `|x| < 1.0`.

Returns

s	Value of the function
sp	Value of the derivative vs x

scipy.special.obl_rad2

scipy.special.**obl_rad2**(*m*, *n*, *c*, *x*) **= <ufunc 'obl_rad2'>**

Oblate spheroidal radial function of the second kind and its derivative.

Computes the oblate spheroidal radial function of the second kind and its derivative (with respect to *x*) for mode parameters m>=0 and n>=m, spheroidal parameter *c* and `|x| < 1.0`.

Returns

s	Value of the function
sp	Value of the derivative vs x

scipy.special.pro_cv

scipy.special.**pro_cv**(*m*, *n*, *c*) **= <ufunc 'pro_cv'>**

Characteristic value of prolate spheroidal function

Computes the characteristic value of prolate spheroidal wave functions of order *m*, *n* (n>=m) and spheroidal parameter *c*.

scipy.special.obl_cv

scipy.special.**obl_cv**(*m*, *n*, *c*) **= <ufunc 'obl_cv'>**

Characteristic value of oblate spheroidal function

Computes the characteristic value of oblate spheroidal wave functions of order *m*, *n* (n>=m) and spheroidal parameter *c*.

scipy.special.pro_cv_seq

scipy.special.**pro_cv_seq**(*m*, *n*, *c*)

Characteristic values for prolate spheroidal wave functions.

Compute a sequence of characteristic values for the prolate spheroidal wave functions for mode m and n'=m..n and spheroidal parameter c.

References

[1]

scipy.special.obl_cv_seq

scipy.special.**obl_cv_seq**(*m*, *n*, *c*)
Characteristic values for oblate spheroidal wave functions.

Compute a sequence of characteristic values for the oblate spheroidal wave functions for mode m and n'=m..n and spheroidal parameter c.

References

[1]

The following functions require pre-computed characteristic value:

pro_ang1_cv(m, n, c, cv, x)	Prolate spheroidal angular function pro_ang1 for precomputed characteristic value
pro_rad1_cv(m, n, c, cv, x)	Prolate spheroidal radial function pro_rad1 for precomputed characteristic value
pro_rad2_cv(m, n, c, cv, x)	Prolate spheroidal radial function pro_rad2 for precomputed characteristic value
obl_ang1_cv(m, n, c, cv, x)	Oblate spheroidal angular function obl_ang1 for precomputed characteristic value
obl_rad1_cv(m, n, c, cv, x)	Oblate spheroidal radial function obl_rad1 for precomputed characteristic value
obl_rad2_cv(m, n, c, cv, x)	Oblate spheroidal radial function obl_rad2 for precomputed characteristic value

scipy.special.pro_ang1_cv

scipy.special.**pro_ang1_cv**(*m*, *n*, *c*, *cv*, *x*) **= <ufunc 'pro_ang1_cv'>**
Prolate spheroidal angular function pro_ang1 for precomputed characteristic value

Computes the prolate spheroidal angular function of the first kind and its derivative (with respect to *x*) for mode parameters m>=0 and n>=m, spheroidal parameter *c* and `|x| < 1.0`. Requires pre-computed characteristic value.

Returns

s	Value of the function
sp	Value of the derivative vs x

scipy.special.pro_rad1_cv

scipy.special.**pro_rad1_cv**(*m*, *n*, *c*, *cv*, *x*) **= <ufunc 'pro_rad1_cv'>**

Prolate spheroidal radial function pro_rad1 for precomputed characteristic value

Computes the prolate spheroidal radial function of the first kind and its derivative (with respect to *x*) for mode parameters m>=0 and n>=m, spheroidal parameter *c* and `|x| < 1.0`. Requires pre-computed characteristic value.

Returns

s	Value of the function
sp	Value of the derivative vs x

scipy.special.pro_rad2_cv

scipy.special.**pro_rad2_cv**(*m*, *n*, *c*, *cv*, *x*) **= <ufunc 'pro_rad2_cv'>**

Prolate spheroidal radial function pro_rad2 for precomputed characteristic value

Computes the prolate spheroidal radial function of the second kind and its derivative (with respect to *x*) for mode parameters m>=0 and n>=m, spheroidal parameter *c* and `|x| < 1.0`. Requires pre-computed characteristic value.

Returns

s	Value of the function
sp	Value of the derivative vs x

scipy.special.obl_ang1_cv

scipy.special.**obl_ang1_cv**(*m*, *n*, *c*, *cv*, *x*) **= <ufunc 'obl_ang1_cv'>**

Oblate spheroidal angular function obl_ang1 for precomputed characteristic value

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to *x*) for mode parameters m>=0 and n>=m, spheroidal parameter *c* and `|x| < 1.0`. Requires pre-computed characteristic value.

Returns

s	Value of the function
sp	Value of the derivative vs x

scipy.special.obl_rad1_cv

scipy.special.**obl_rad1_cv**(*m*, *n*, *c*, *cv*, *x*) **= <ufunc 'obl_rad1_cv'>**

Oblate spheroidal radial function obl_rad1 for precomputed characteristic value

Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to *x*) for mode parameters m>=0 and n>=m, spheroidal parameter *c* and `|x| < 1.0`. Requires pre-computed characteristic value.

Returns

s	Value of the function
sp	Value of the derivative vs x

scipy.special.obl_rad2_cv

scipy.special.**obl_rad2_cv**(*m*, *n*, *c*, *cv*, *x*) **= <ufunc 'obl_rad2_cv'>**

Oblate spheroidal radial function obl_rad2 for precomputed characteristic value

Computes the oblate spheroidal radial function of the second kind and its derivative (with respect to *x*) for mode parameters m>=0 and n>=m, spheroidal parameter *c* and `|x| < 1.0`. Requires pre-computed characteristic value.

Returns

s	Value of the function
sp	Value of the derivative vs x

Kelvin functions

kelvin(x)	Kelvin functions as complex numbers
kelvin_zeros(nt)	Compute nt zeros of all Kelvin functions.
ber(x[, out])	Kelvin function ber.
bei(x[, out])	Kelvin function bei.
berp(x[, out])	Derivative of the Kelvin function ber.
beip(x[, out])	Derivative of the Kelvin function bei.
ker(x[, out])	Kelvin function ker.
kei(x[, out])	Kelvin function kei.
kerp(x[, out])	Derivative of the Kelvin function ker.
keip(x[, out])	Derivative of the Kelvin function kei.

scipy.special.kelvin

scipy.special.**kelvin**(*x*) **= <ufunc 'kelvin'>**

Kelvin functions as complex numbers

Returns

Be, Ke, Bep, Kep
: The tuple (Be, Ke, Bep, Kep) contains complex numbers representing the real and imaginary Kelvin functions and their derivatives evaluated at *x*. For example, kelvin(x)[0].real = ber x and kelvin(x)[0].imag = bei x with similar relationships for ker and kei.

scipy.special.kelvin_zeros

scipy.special.**kelvin_zeros**(*nt*)

Compute nt zeros of all Kelvin functions.

Returned in a length-8 tuple of arrays of length nt. The tuple contains the arrays of zeros of (ber, bei, ker, kei, ber', bei', ker', kei').

References

[1]

scipy.special.ber

scipy.special.**ber**(*x*, *out=None*) **= <ufunc 'ber'>**

Kelvin function ber.

Defined as

$$\mathrm{ber}(x) = \Re[J_0(xe^{3\pi i/4})]$$

where J_0 is the Bessel function of the first kind of order zero (see `jv`). See [dlmf] for more details.

Parameters

x [array_like] Real argument.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Values of the Kelvin function.

See also:

bei

the corresponding real part

berp

the derivative of bei

jv

Bessel function of the first kind

References

[dlmf]

Examples

It can be expressed using Bessel functions.

```
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.jv(0, x * np.exp(3 * np.pi * 1j / 4)).real
array([ 0.98438178,  0.75173418, -0.22138025, -2.56341656])
>>> sc.ber(x)
array([ 0.98438178,  0.75173418, -0.22138025, -2.56341656])
```

scipy.special.bei

scipy.special.**bei**(*x*, *out=None*) **= <ufunc 'bei'>**

Kelvin function bei.

Defined as

$$\mathrm{bei}(x) = \Im[J_0(xe^{3\pi i/4})]$$

where J_0 is the Bessel function of the first kind of order zero (see `jv`). See [dlmf] for more details.

Parameters

x	[array_like] Real argument.
out	[ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Values of the Kelvin function.

See also:

ber

the corresponding real part

beip

the derivative of bei

jv

Bessel function of the first kind

References

[dlmf]

Examples

It can be expressed using Bessel functions.

```
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.jv(0, x * np.exp(3 * np.pi * 1j / 4)).imag
array([0.24956604, 0.97229163, 1.93758679, 2.29269032])
>>> sc.bei(x)
array([0.24956604, 0.97229163, 1.93758679, 2.29269032])
```

scipy.special.berp

scipy.special.**berp**(*x*, *out=None*) **= <ufunc 'berp'>**

Derivative of the Kelvin function ber.

Parameters

x [array_like] Real argument.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
The values of the derivative of ber.

See also:

ber

References

[dlmf]

scipy.special.beip

scipy.special.**beip**(*x*, *out=None*) **= <ufunc 'beip'>**

Derivative of the Kelvin function bei.

Parameters

x [array_like] Real argument.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
The values of the derivative of bei.

See also:

bei

References

[dlmf]

scipy.special.ker

scipy.special.**ker**(*x*, *out=None*) **= <ufunc 'ker'>**

Kelvin function ker.

Defined as

$$\mathrm{ker}(x) = \Re[K_0(xe^{\pi i/4})]$$

Where K_0 is the modified Bessel function of the second kind (see `kv`). See [dlmf] for more details.

Parameters

x	[array_like] Real argument.
out	[ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Values of the Kelvin function.

See also:

kei

the corresponding imaginary part

kerp

the derivative of ker

kv

modified Bessel function of the second kind

References

[dlmf]

Examples

It can be expressed using the modified Bessel function of the second kind.

```
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.kv(0, x * np.exp(np.pi * 1j / 4)).real
array([ 0.28670621, -0.04166451, -0.06702923, -0.03617885])
>>> sc.ker(x)
array([ 0.28670621, -0.04166451, -0.06702923, -0.03617885])
```

scipy.special.kei

scipy.special.**kei**(*x*, *out=None*) **= <ufunc 'kei'>**

Kelvin function kei.

Defined as

$$\mathrm{kei}(x) = \Im[K_0(xe^{\pi i/4})]$$

where K_0 is the modified Bessel function of the second kind (see `kv`). See [dlmf] for more details.

Parameters

x	[array_like] Real argument.
out	[ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Values of the Kelvin function.

See also:

ker

the corresponding real part

keip

the derivative of kei

kv

modified Bessel function of the second kind

References

[dlmf]

Examples

It can be expressed using the modified Bessel function of the second kind.

```
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.kv(0, x * np.exp(np.pi * 1j / 4)).imag
array([-0.49499464, -0.20240007, -0.05112188,  0.0021984 ])
>>> sc.kei(x)
array([-0.49499464, -0.20240007, -0.05112188,  0.0021984 ])
```

scipy.special.kerp

scipy.special.**kerp**(*x*, *out=None*) **= <ufunc 'kerp'>**

Derivative of the Kelvin function ker.

Parameters

x [array_like] Real argument.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Values of the derivative of ker.

See also:

ker

References

[dlmf]

scipy.special.keip

scipy.special.**keip**(*x*, *out=None*) **= <ufunc 'keip'>**

Derivative of the Kelvin function kei.

Parameters

x [array_like] Real argument.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
The values of the derivative of kei.

See also:

kei

Returns

ndarray First *nt* zeros of the derivative of the Kelvin function.

See also:

kei, **keip**

References

[1]

Combinatorics

comb(N, k[, exact, repetition])	The number of combinations of N things taken k at a time.
perm(N, k[, exact])	Permutations of N things taken k at a time, i.e., k-permutations of N.

scipy.special.comb

scipy.special.**comb**(*N*, *k*, *exact=False*, *repetition=False*)

The number of combinations of N things taken k at a time.

This is often expressed as “N choose k”.

Parameters

N [int, ndarray] Number of things.

k [int, ndarray] Number of elements taken.

exact [bool, optional] If *exact* is False, then floating point precision is used, otherwise exact long integer is computed.

repetition [bool, optional] If *repetition* is True, then the number of combinations with repetition is computed.

Returns

val [int, float, ndarray] The total number of combinations.

See also:

binom

Binomial coefficient ufunc

Notes

- Array arguments accepted only for exact=False case.
- If N < 0, or k < 0, then 0 is returned.
- If k > N and repetition=False, then 0 is returned.

Examples

```
>>> from scipy.special import comb
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> comb(n, k, exact=False)
array([ 120.,  210.])
>>> comb(10, 3, exact=True)
120
>>> comb(10, 3, exact=True, repetition=True)
220
```

scipy.special.perm

scipy.special.**perm**(*N*, *k*, *exact=False*)

Permutations of N things taken k at a time, i.e., k-permutations of N.

It's also known as "partial permutations".

Parameters

N	[int, ndarray] Number of things.
k	[int, ndarray] Number of elements taken.
exact	[bool, optional] If *exact* is False, then floating point precision is used, otherwise exact long integer is computed.

Returns

val	[int, ndarray] The number of k-permutations of N.

Notes

- Array arguments accepted only for exact=False case.
- If k > N, N < 0, or k < 0, then a 0 is returned.

Examples

```
>>> from scipy.special import perm
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> perm(n, k)
array([  720.,  5040.])
>>> perm(10, 3, exact=True)
720
```

Lambert W and related functions

lambertw(z[, k, tol])	Lambert W function.
wrightomega(z[, out])	Wright Omega function.

scipy.special.lambertw

scipy.special.**lambertw**(*z*, *k=0*, *tol=1e-8*)

Lambert W function.

The Lambert W function *W(z)* is defined as the inverse function of `w * exp(w)`. In other words, the value of `W(z)` is such that `z = W(z) * exp(W(z))` for any complex number `z`.

The Lambert W function is a multivalued function with infinitely many branches. Each branch gives a separate solution of the equation `z = w exp(w)`. Here, the branches are indexed by the integer *k*.

Parameters

z	[array_like] Input argument.
k	[int, optional] Branch index.
tol	[float, optional] Evaluation tolerance.

Returns

w	[array] *w* will have the same shape as *z*.

See also:

wrightomega

the Wright Omega function

Notes

All branches are supported by *lambertw*:

- `lambertw(z)` gives the principal solution (branch 0)
- `lambertw(z, k)` gives the solution on branch *k*

The Lambert W function has two partially real branches: the principal branch (*k = 0*) is real for real `z > -1/e`, and the `k = -1` branch is real for `-1/e < z < 0`. All branches except `k = 0` have a logarithmic singularity at `z = 0`.

Possible issues

The evaluation can become inaccurate very close to the branch point at `-1/e`. In some corner cases, *lambertw* might currently fail to converge, or can end up on the wrong branch.

Algorithm

Halley's iteration is used to invert `w * exp(w)`, using a first-order asymptotic approximation (O(log(w)) or *O(w)*) as the initial estimate.

The definition, implementation and choice of branches is based on [2].

References

[1], [2]

Examples

The Lambert W function is the inverse of `w exp(w)`:

```
>>> from scipy.special import lambertw
>>> w = lambertw(1)
>>> w
(0.56714329040978384+0j)
>>> w * np.exp(w)
(1.0+0j)
```

Any branch gives a valid inverse:

```
>>> w = lambertw(1, k=3)
>>> w
(-2.8535817554090377+17.113535539412148j)
>>> w*np.exp(w)
(1.0000000000000002+1.609823385706477e-15j)
```

Applications to equation-solving

The Lambert W function may be used to solve various kinds of equations, such as finding the value of the infinite power tower $z^{z^{z^{\cdots}}}$:

```
>>> def tower(z, n):
...     if n == 0:
...         return z
...     return z ** tower(z, n-1)
...
>>> tower(0.5, 100)
0.641185744504986
>>> -lambertw(-np.log(0.5)) / np.log(0.5)
(0.64118574450498589+0j)
```

scipy.special.wrightomega

scipy.special.**wrightomega**(*z*, *out=None*) **= <ufunc 'wrightomega'>**

Wright Omega function.

Defined as the solution to

$$\omega + \log(\omega) = z$$

where $\log$ is the principal branch of the complex logarithm.

Parameters

z [array_like] Points at which to evaluate the Wright Omega function

Returns

omega [ndarray] Values of the Wright Omega function

See also:

lambertw

The Lambert W function

Notes

New in version 0.19.0.

The function can also be defined as

$$\omega(z) = W_{K(z)}(e^z)$$

where $K(z) = \lceil (\Im(z) - \pi)/(2\pi) \rceil$ is the unwinding number and W is the Lambert W function.

The implementation here is taken from [1].

References

[1]

Other special functions

agm(a, b)	Compute the arithmetic-geometric mean of *a* and *b*.
bernoulli(n)	Bernoulli numbers B0..Bn (inclusive).
binom(n, k)	Binomial coefficient
diric(x, n)	Periodic sinc function, also called the Dirichlet function.
euler(n)	Euler numbers E(0), E(1), …, E(n).
expn(n, x[, out])	Generalized exponential integral En.
exp1(z[, out])	Exponential integral E1.
expi(x[, out])	Exponential integral Ei.
factorial(n[, exact])	The factorial of a number or array of numbers.
factorial2(n[, exact])	Double factorial.
factorialk(n, k[, exact])	Multifactorial of n of order k, n(!!…!).
shichi(x[, out])	Hyperbolic sine and cosine integrals.
sici(x[, out])	Sine and cosine integrals.
softmax(x[, axis])	Softmax function
log_softmax(x[, axis])	Logarithm of softmax function.
spence(z[, out])	Spence's function, also known as the dilogarithm.
zeta(x[, q, out])	Riemann or Hurwitz zeta function.
zetac(x)	Riemann zeta function minus 1.

scipy.special.agm

scipy.special.**agm**(*a*, *b*) **= <ufunc 'agm'>**

Compute the arithmetic-geometric mean of *a* and *b*.

Start with a_0 = a and b_0 = b and iteratively compute:

```
a_{n+1} = (a_n + b_n)/2
b_{n+1} = sqrt(a_n*b_n)
```

a_n and b_n converge to the same limit as n increases; their common limit is agm(a, b).

Parameters

a, b [array_like] Real values only. If the values are both negative, the result is negative. If one value is negative and the other is positive, *nan* is returned.

Returns

float The arithmetic-geometric mean of *a* and *b*.

Examples

```
>>> from scipy.special import agm
>>> a, b = 24.0, 6.0
>>> agm(a, b)
13.458171481725614
```

Compare that result to the iteration:

```
>>> while a != b:
...     a, b = (a + b)/2, np.sqrt(a*b)
...     print("a = %19.16f  b=%19.16f" % (a, b))
...
a = 15.0000000000000000  b=12.0000000000000000
a = 13.5000000000000000  b=13.4164078649987388
a = 13.4582039324993694  b=13.4581390309909850
a = 13.4581714817451772  b=13.4581714817060547
a = 13.4581714817256159  b=13.4581714817256159
```

When array-like arguments are given, broadcasting applies:

```
>>> a = np.array([[1.5], [3], [6]])  # a has shape (3, 1).
>>> b = np.array([6, 12, 24, 48])    # b has shape (4,).
>>> agm(a, b)
array([[  3.36454287,   5.42363427,   9.05798751,  15.53650756],
       [  4.37037309,   6.72908574,  10.84726853,  18.11597502],
       [  6.        ,   8.74074619,  13.45817148,  21.69453707]])
```

scipy.special.bernoulli

scipy.special.**bernoulli**(*n*)

Bernoulli numbers B0..Bn (inclusive).

Parameters

n [int] Indicated the number of terms in the Bernoulli series to generate.

Returns

ndarray The Bernoulli numbers `[B(0), B(1), ..., B(n)]`.

References

[1], [2]

Examples

```
>>> from scipy.special import bernoulli, zeta
>>> bernoulli(4)
array([ 1.        , -0.5       ,  0.16666667,  0.        , -0.03333333])
```

The Wikipedia article ([2]) points out the relationship between the Bernoulli numbers and the zeta function, `B_n^+ = -n * zeta(1 - n)` for `n > 0`:

```
>>> n = np.arange(1, 5)
>>> -n * zeta(1 - n)
array([ 0.5       ,  0.16666667, -0.        , -0.03333333])
```

Note that, in the notation used in the wikipedia article, *bernoulli* computes `B_n^-` (i.e. it used the convention that `B_1` is -1/2). The relation given above is for `B_n^+`, so the sign of 0.5 does not match the output of `bernoulli(4)`.

scipy.special.binom

scipy.special.**binom**(*n*, *k*) **= <ufunc 'binom'>**

Binomial coefficient

See also:

comb

The number of combinations of N things taken k at a time.

scipy.special.diric

scipy.special.**diric**(*x*, *n*)

Periodic sinc function, also called the Dirichlet function.

The Dirichlet function is defined as:

```
diric(x, n) = sin(x * n/2) / (n * sin(x / 2)),
```

where *n* is a positive integer.

Parameters

x	[array_like] Input data
n	[int] Integer defining the periodicity.

Returns

diric	[ndarray]

Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-8*np.pi, 8*np.pi, num=201)
>>> plt.figure(figsize=(8, 8));
>>> for idx, n in enumerate([2, 3, 4, 9]):
...     plt.subplot(2, 2, idx+1)
...     plt.plot(x, special.diric(x, n))
...     plt.title('diric, n={}'.format(n))
>>> plt.show()
```

The following example demonstrates that *diric* gives the magnitudes (modulo the sign and scaling) of the Fourier coefficients of a rectangular pulse.

Suppress output of values that are effectively 0:

```
>>> np.set_printoptions(suppress=True)
```

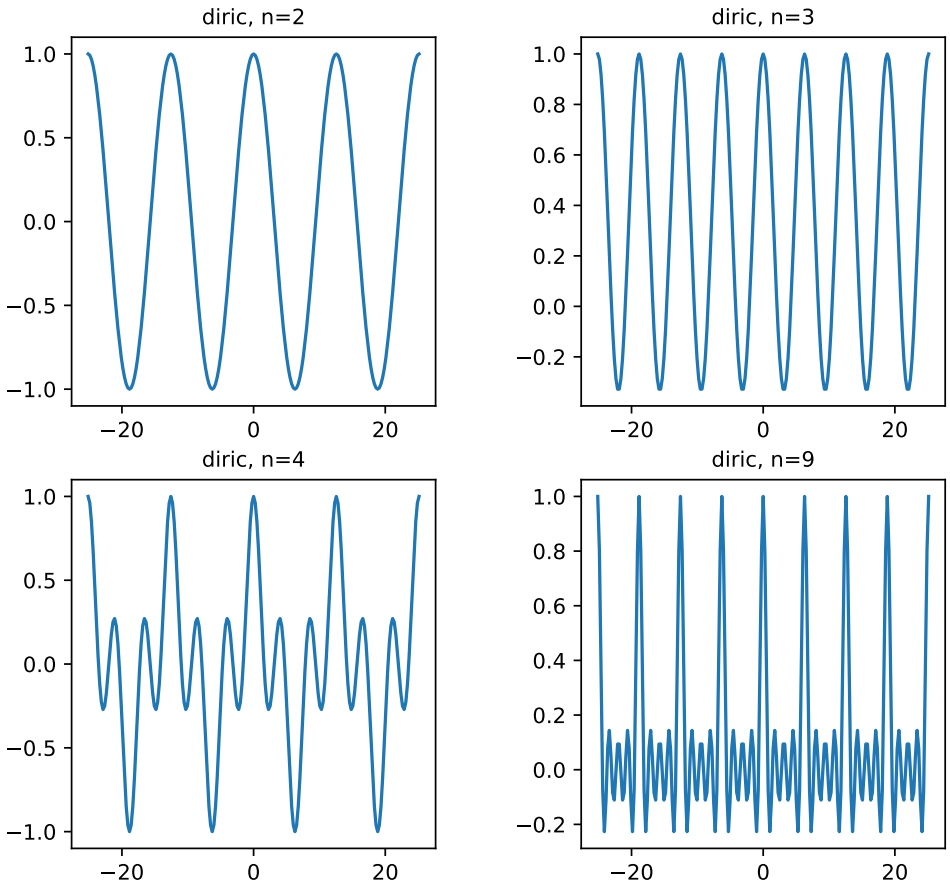
Create a signal *x* of length *m* with *k* ones:

```
>>> m = 8
>>> k = 3
>>> x = np.zeros(m)
>>> x[:k] = 1
```

Use the FFT to compute the Fourier transform of *x*, and inspect the magnitudes of the coefficients:

```
>>> np.abs(np.fft.fft(x))
array([ 3.        ,  2.41421356,  1.        ,  0.41421356,  1.        ,
        0.41421356,  1.        ,  2.41421356])
```

Now find the same values (up to sign) using *diric*. We multiply by *k* to account for the different scaling conventions of `numpy.fft.fft` and *diric*:



diric, n=2
diric, n=3
diric, n=4
diric, n=9
1.0
0.5
0.0
−0.5
−1.0
0.8
0.6
0.4
0.2
−0.2
−20
0
20

```
>>> theta = np.linspace(0, 2*np.pi, m, endpoint=False)
>>> k * special.diric(theta, k)
array([ 3.        ,  2.41421356,  1.        , -0.41421356, -1.        ,
       -0.41421356,  1.        ,  2.41421356])
```

scipy.special.euler

scipy.special.**euler**(*n*)

Euler numbers E(0), E(1), …, E(n).

The Euler numbers [1] are also known as the secant numbers.

Because `euler(n)` returns floating point values, it does not give exact values for large *n*. The first inexact value is E(22).

Parameters

n [int] The highest index of the Euler number to be returned.

Returns

ndarray The Euler numbers [E(0), E(1), …, E(n)]. The odd Euler numbers, which are all zero, are included.

References

[1], [2]

Examples

```
>>> from scipy.special import euler
>>> euler(6)
array([  1.,   0.,  -1.,   0.,   5.,   0., -61.])
```

```
>>> euler(13).astype(np.int64)
array([      1,       0,      -1,       0,       5,       0,     -61,
            0,    1385,       0,  -50521,       0, 2702765,       0])
```

```
>>> euler(22)[-1]  # Exact value of E(22) is -69348874393137901.
-69348874393137976.0
```

scipy.special.expn

scipy.special.**expn**(*n*, *x*, *out=None*) **= <ufunc 'expn'>**

Generalized exponential integral En.

For integer $n \geq 0$ and real $x \geq 0$ the generalized exponential integral is defined as [dlmf]

$$E_n(x) = x^{n-1} \int_x^\infty \frac{e^{-t}}{t^n} dt.$$

Parameters

n: array_like
Non-negative integers
x: array_like
Real argument
out: ndarray, optional
Optional output array for the function results

Returns

scalar or ndarray
Values of the generalized exponential integral

See also:

exp1

special case of E_n for $n = 1$

expi

related to E_n when $n = 1$

References

[dlmf]

Examples

```
>>> import scipy.special as sc
```

Its domain is nonnegative n and x.

```
>>> sc.expn(-1, 1.0), sc.expn(1, -1.0)
(nan, nan)
```

It has a pole at `x = 0` for `n = 1, 2`; for larger `n` it is equal to `1 / (n - 1)`.

```
>>> sc.expn([0, 1, 2, 3, 4], 0)
array([       inf,        inf, 1.        , 0.5       , 0.33333333])
```

For n equal to 0 it reduces to `exp(-x) / x`.

```
>>> x = np.array([1, 2, 3, 4])
>>> sc.expn(0, x)
array([0.36787944, 0.06766764, 0.01659569, 0.00457891])
>>> np.exp(-x) / x
array([0.36787944, 0.06766764, 0.01659569, 0.00457891])
```

For n equal to 1 it reduces to *exp1*.

```
>>> sc.expn(1, x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
>>> sc.exp1(x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
```

scipy.special.exp1

scipy.special.**exp1**(*z*, *out=None*) **= <ufunc 'exp1'>**

Exponential integral E1.

For complex $z \neq 0$ the exponential integral can be defined as [1]

$$E_1(z) = \int_z^\infty \frac{e^{-t}}{t} dt,$$

where the path of the integral does not cross the negative real axis or pass through the origin.

Parameters

z: array_like
Real or complex argument.

out: ndarray, optional
Optional output array for the function results

Returns

scalar or ndarray
Values of the exponential integral E1

See also:

expi

exponential integral Ei

expn

generalization of E_1

Notes

For $x > 0$ it is related to the exponential integral Ei (see *expi*) via the relation

$$E_1(x) = -Ei(-x).$$

References

[1]

Examples

```
>>> import scipy.special as sc
```

It has a pole at 0.

```
>>> sc.exp1(0)
inf
```

It has a branch cut on the negative real axis.

```
>>> sc.exp1(-1)
nan
>>> sc.exp1(complex(-1, 0))
(-1.8951178163559368-3.141592653589793j)
>>> sc.exp1(complex(-1, -0.0))
(-1.8951178163559368+3.141592653589793j)
```

It approaches 0 along the positive real axis.

```
>>> sc.exp1([1, 10, 100, 1000])
array([2.19383934e-01, 4.15696893e-06, 3.68359776e-46, 0.00000000e+00])
```

It is related to *expi*.

```
>>> x = np.array([1, 2, 3, 4])
>>> sc.exp1(x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
>>> -sc.expi(-x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
```

scipy.special.expi

scipy.special.**expi**(*x*, *out=None*) **= <ufunc 'expi'>**

Exponential integral Ei.

For real x, the exponential integral is defined as [1]

$$Ei(x) = \int_{-\infty}^{x} \frac{e^t}{t} dt.$$

For $x > 0$ the integral is understood as a Cauchy principle value.

It is extended to the complex plane by analytic continuation of the function on the interval $(0, \infty)$. The complex variant has a branch cut on the negative real axis.

Parameters

x: array_like
Real or complex valued argument

out: ndarray, optional
Optional output array for the function results

Returns

scalar or ndarray
Values of the exponential integral

See also:

exp1

Exponential integral E_1

expn

Generalized exponential integral E_n

Notes

The exponential integrals E_1 and Ei satisfy the relation

$$E_1(x) = -Ei(-x)$$

for $x > 0$.

References

[1]

Examples

```
>>> import scipy.special as sc
```

It is related to *exp1*.

```
>>> x = np.array([1, 2, 3, 4])
>>> -sc.expi(-x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
>>> sc.exp1(x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
```

The complex variant has a branch cut on the negative real axis.

```
>>> import scipy.special as sc
>>> sc.expi(-1 + 1e-12j)
(-0.21938393439552062+3.1415926535894254j)
>>> sc.expi(-1 - 1e-12j)
(-0.21938393439552062-3.1415926535894254j)
```

As the complex variant approaches the branch cut, the real parts approach the value of the real variant.

```
>>> sc.expi(-1)
-0.21938393439552062
```

The SciPy implementation returns the real variant for complex values on the branch cut.

```
>>> sc.expi(complex(-1, 0.0))
(-0.21938393439552062-0j)
>>> sc.expi(complex(-1, -0.0))
(-0.21938393439552062-0j)
```

scipy.special.factorial

scipy.special.**factorial**(*n*, *exact=False*)

The factorial of a number or array of numbers.

The factorial of non-negative integer *n* is the product of all positive integers less than or equal to *n*:

```
n! = n * (n - 1) * (n - 2) * ... * 1
```

Parameters

n : [int or array_like of ints] Input values. If `n < 0`, the return value is 0.

exact : [bool, optional] If True, calculate the answer exactly using long integer arithmetic. If False, result is approximated in floating point rapidly using the *gamma* function. Default is False.

Returns

nf : [float or int or ndarray] Factorial of *n*, as integer or float depending on *exact*.

Notes

For arrays with `exact=True`, the factorial is computed only once, for the largest input, with each other result computed in the process. The output dtype is increased to `int64` or `object` if necessary.

With `exact=False` the factorial is approximated using the gamma function:

$$n! = \Gamma(n+1)$$

Examples

```
>>> from scipy.special import factorial
>>> arr = np.array([3, 4, 5])
>>> factorial(arr, exact=False)
array([   6.,   24.,  120.])
>>> factorial(arr, exact=True)
array([  6,  24, 120])
>>> factorial(5, exact=True)
120
```

scipy.special.factorial2

scipy.special.**factorial2**(*n*, *exact=False*)

Double factorial.

This is the factorial with every second value skipped. E.g., `7!! = 7 * 5 * 3 * 1`. It can be approximated numerically as:

```
n!! = special.gamma(n/2+1)*2**((m+1)/2)/sqrt(pi)  n odd
    = 2**(n/2) * (n/2)!                           n even
```

Parameters

n [int or array_like] Calculate `n!!`. Arrays are only supported with *exact* set to False. If `n < 0`, the return value is 0.

exact [bool, optional] The result can be approximated rapidly using the gamma-formula above (default). If *exact* is set to True, calculate the answer exactly using integer arithmetic.

Returns

nff [float or int] Double factorial of *n*, as an int or a float depending on *exact*.

Examples

```
>>> from scipy.special import factorial2
>>> factorial2(7, exact=False)
array(105.00000000000001)
>>> factorial2(7, exact=True)
105
```

scipy.special.factorialk

scipy.special.**factorialk**(*n*, *k*, *exact=True*)

Multifactorial of n of order k, n(!!...!).

This is the multifactorial of n skipping k values. For example,

factorialk(17, 4) = 17!!!! = 17 * 13 * 9 * 5 * 1

In particular, for any integer `n`, we have

factorialk(n, 1) = factorial(n)
factorialk(n, 2) = factorial2(n)

Parameters

n [int] Calculate multifactorial. If *n* < 0, the return value is 0.

k [int] Order of multifactorial.

exact [bool, optional] If exact is set to True, calculate the answer exactly using integer arithmetic.

Returns

val [int] Multifactorial of *n*.

Raises

NotImplementedError
Raises when exact is False

Examples

```
>>> from scipy.special import factorialk
>>> factorialk(5, 1, exact=True)
120
>>> factorialk(5, 3, exact=True)
10
```

scipy.special.shichi

scipy.special.**shichi**(*x*, *out=None*) **= <ufunc 'shichi'>**

Hyperbolic sine and cosine integrals.

The hyperbolic sine integral is

$$\int_0^x \frac{\sinh t}{t} dt$$

and the hyperbolic cosine integral is

$$\gamma + \log(x) + \int_0^x \frac{\cosh t - 1}{t} dt$$

where γ is Euler's constant and $\log$ is the principle branch of the logarithm.

Parameters

x [array_like] Real or complex points at which to compute the hyperbolic sine and cosine integrals.

Returns

si [ndarray] Hyperbolic sine integral at `x`
ci [ndarray] Hyperbolic cosine integral at `x`

Notes

For real arguments with `x < 0`, `chi` is the real part of the hyperbolic cosine integral. For such points `chi(x)` and `chi(x + 0j)` differ by a factor of `1j*pi`.

For real arguments the function is computed by calling Cephes' [1] *shichi* routine. For complex arguments the algorithm is based on Mpmath's [2] *shi* and *chi* routines.

References

[1], [2]

scipy.special.sici

scipy.special.**sici**(*x*, *out=None*) **= <ufunc 'sici'>**

Sine and cosine integrals.

The sine integral is

$$\int_0^x \frac{\sin t}{t} dt$$

and the cosine integral is

$$\gamma + \log(x) + \int_0^x \frac{\cos t - 1}{t} dt$$

where γ is Euler's constant and $\log$ is the principle branch of the logarithm.

Parameters

x [array_like] Real or complex points at which to compute the sine and cosine integrals.

Returns

si [ndarray] Sine integral at `x`
ci [ndarray] Cosine integral at `x`

Notes

For real arguments with `x < 0`, `ci` is the real part of the cosine integral. For such points `ci(x)` and `ci(x + 0j)` differ by a factor of `1j*pi`.

For real arguments the function is computed by calling Cephes' [1] *sici* routine. For complex arguments the algorithm is based on Mpmath's [2] *si* and *ci* routines.

References

[1], [2]

scipy.special.softmax

`scipy.special.`**`softmax`**(*x*, *axis=None*)
Softmax function

The softmax function transforms each element of a collection by computing the exponential of each element divided by the sum of the exponentials of all the elements. That is, if *x* is a one-dimensional numpy array:

```
softmax(x) = np.exp(x)/sum(np.exp(x))
```

Parameters

x [array_like] Input array.
axis [int or tuple of ints, optional] Axis to compute values along. Default is None and softmax will be computed over the entire array *x*.

Returns

s [ndarray] An array the same shape as *x*. The result will sum to 1 along the specified axis.

Notes

The formula for the softmax function $\sigma(x)$ for a vector $x = \{x_0, x_1, ..., x_{n-1}\}$ is

$$\sigma(x)_j = \frac{e^{x_j}}{\sum_k e^{x_k}}$$

The *softmax* function is the gradient of *logsumexp*.

New in version 1.2.0.

Examples

```
>>> from scipy.special import softmax
>>> np.set_printoptions(precision=5)
```

```
>>> x = np.array([[1, 0.5, 0.2, 3],
...               [1,  -1,   7, 3],
...               [2,  12,  13, 3]])
...
```

Compute the softmax transformation over the entire array.

```
>>> m = softmax(x)
>>> m
array([[  4.48309e-06,   2.71913e-06,   2.01438e-06,   3.31258e-05],
       [  4.48309e-06,   6.06720e-07,   1.80861e-03,   3.31258e-05],
       [  1.21863e-05,   2.68421e-01,   7.29644e-01,   3.31258e-05]])
```

```
>>> m.sum()
1.0000000000000002
```

Compute the softmax transformation along the first axis (i.e., the columns).

```
>>> m = softmax(x, axis=0)
```

```
>>> m
array([[  2.11942e-01,   1.01300e-05,   2.75394e-06,   3.33333e-01],
       [  2.11942e-01,   2.26030e-06,   2.47262e-03,   3.33333e-01],
       [  5.76117e-01,   9.99988e-01,   9.97525e-01,   3.33333e-01]])
```

```
>>> m.sum(axis=0)
array([ 1.,  1.,  1.,  1.])
```

Compute the softmax transformation along the second axis (i.e., the rows).

```
>>> m = softmax(x, axis=1)
>>> m
array([[  1.05877e-01,   6.42177e-02,   4.75736e-02,   7.82332e-01],
       [  2.42746e-03,   3.28521e-04,   9.79307e-01,   1.79366e-02],
       [  1.22094e-05,   2.68929e-01,   7.31025e-01,   3.31885e-05]])
```

```
>>> m.sum(axis=1)
array([ 1.,  1.,  1.])
```

scipy.special.log_softmax

scipy.special.**log_softmax**(*x*, *axis=None*)

Logarithm of softmax function:

```
log_softmax(x) = log(softmax(x))
```

Parameters

x	[array_like] Input array.
axis	[int or tuple of ints, optional] Axis to compute values along. Default is None and softmax will be computed over the entire array *x*.

Returns

s	[ndarray or scalar] An array with the same shape as *x*. Exponential of the result will sum to 1 along the specified axis. If *x* is a scalar, a scalar is returned.

Notes

log_softmax is more accurate than `np.log(softmax(x))` with inputs that make *softmax* saturate (see examples below).

New in version 1.5.0.

Examples

```
>>> from scipy.special import log_softmax
>>> from scipy.special import softmax
>>> np.set_printoptions(precision=5)
```

```
>>> x = np.array([1000.0, 1.0])
```

```
>>> y = log_softmax(x)
>>> y
array([   0., -999.])
```

```
>>> with np.errstate(divide='ignore'):
...   y = np.log(softmax(x))
...
>>> y
array([  0., -inf])
```

scipy.special.spence

scipy.special.**spence**(*z*, *out=None*) **= <ufunc 'spence'>**

Spence's function, also known as the dilogarithm.

It is defined to be

$$\int_1^z \frac{\log(t)}{1-t}dt$$

for complex z, where the contour of integration is taken to avoid the branch cut of the logarithm. Spence's function is analytic everywhere except the negative real axis where it has a branch cut.

Parameters

z [array_like] Points at which to evaluate Spence's function

Returns

s [ndarray] Computed values of Spence's function

Notes

There is a different convention which defines Spence's function by the integral

$$-\int_0^z \frac{\log(1-t)}{t}dt;$$

this is our `spence(1 - z)`.

scipy.special.zeta

scipy.special.**zeta**(*x*, *q=None*, *out=None*)

Riemann or Hurwitz zeta function.

Parameters

x [array_like of float] Input data, must be real
q [array_like of float, optional] Input data, must be real. Defaults to Riemann zeta.
out [ndarray, optional] Output array for the computed values.

Returns

out [array_like] Values of zeta(x).

See also:

`zetac`

Notes

The two-argument version is the Hurwitz zeta function

$$\zeta(x, q) = \sum_{k=0}^{\infty} \frac{1}{(k+q)^x};$$

see [dlmf] for details. The Riemann zeta function corresponds to the case when `q = 1`.

References

[dlmf]

Examples

```
>>> from scipy.special import zeta, polygamma, factorial
```

Some specific values:

```
>>> zeta(2), np.pi**2/6
(1.6449340668482266, 1.6449340668482264)
```

```
>>> zeta(4), np.pi**4/90
(1.0823232337111381, 1.082323233711138)
```

Relation to the *polygamma* function:

```
>>> m = 3
>>> x = 1.25
>>> polygamma(m, x)
array(2.782144009188397)
>>> (-1)**(m+1) * factorial(m) * zeta(m+1, x)
2.7821440091883969
```

scipy.special.zetac

scipy.special.**zetac**(*x*) **= <ufunc 'zetac'>**

Riemann zeta function minus 1.

This function is defined as

$$\zeta(x) = \sum_{k=2}^{\infty} 1/k^x,$$

where `x > 1`. For `x < 1` the analytic continuation is computed. For more information on the Riemann zeta function, see [dlmf].

Parameters

x [array_like of float] Values at which to compute zeta(x) - 1 (must be real).

Returns

out [array_like] Values of zeta(x) - 1.

See also:

zeta

References

[dlmf]

Examples

```
>>> from scipy.special import zetac, zeta
```

Some special values:

```
>>> zetac(2), np.pi**2/6 - 1
(0.64493406684822641, 0.6449340668482264)
```

```
>>> zetac(-1), -1.0/12 - 1
(-1.0833333333333333, -1.0833333333333333)
```

Compare `zetac(x)` to `zeta(x) - 1` for large *x*:

```
>>> zetac(60), zeta(60) - 1
(8.673617380119933e-19, 0.0)
```

Convenience functions

cbrt(x)	Element-wise cube root of *x*.
exp10(x)	Compute `10**x` element-wise.
exp2(x)	Compute `2**x` element-wise.
radian(d, m, s[, out])	Convert from degrees to radians.
cosdg(x[, out])	Cosine of the angle *x* given in degrees.
sindg(x[, out])	Sine of the angle *x* given in degrees.
tandg(x[, out])	Tangent of angle *x* given in degrees.
cotdg(x[, out])	Cotangent of the angle *x* given in degrees.
log1p(x[, out])	Calculates log(1 + x) for use when *x* is near zero.
expm1(x)	Compute `exp(x) - 1`.
cosm1(x[, out])	cos(x) - 1 for use when *x* is near zero.
round(x[, out])	Round to the nearest integer.
xlogy(x, y)	Compute `x*log(y)` so that the result is 0 if `x = 0`.
xlog1py(x, y)	Compute `x*log1p(y)` so that the result is 0 if `x = 0`.
logsumexp(a[, axis, b, keepdims, return_sign])	Compute the log of the sum of exponentials of input elements.
exprel(x)	Relative error exponential, `(exp(x) - 1)/x`.
sinc(x)	Return the normalized sinc function.

scipy.special.cbrt

scipy.special.**cbrt**(*x*) = <ufunc 'cbrt'>

Element-wise cube root of *x*.

Parameters

x [array_like] *x* must contain real numbers.

Returns

float The cube root of each value in *x*.

Examples

```
>>> from scipy.special import cbrt
```

```
>>> cbrt(8)
2.0
>>> cbrt([-8, -3, 0.125, 1.331])
array([-2.        , -1.44224957,  0.5       ,  1.1       ])
```

scipy.special.exp10

scipy.special.**exp10**(*x*) = <ufunc 'exp10'>

Compute `10**x` element-wise.

Parameters

x [array_like] *x* must contain real numbers.

Returns

float `10**x`, computed element-wise.

Examples

```
>>> from scipy.special import exp10
```

```
>>> exp10(3)
1000.0
>>> x = np.array([[-1, -0.5, 0], [0.5, 1, 1.5]])
>>> exp10(x)
array([[  0.1       ,   0.31622777,   1.        ],
       [  3.16227766,  10.        ,  31.6227766 ]])
```

scipy.special.exp2

scipy.special.**exp2**(*x*) **= <ufunc 'exp2'>**

Compute `2**x` element-wise.

Parameters

x [array_like] *x* must contain real numbers.

Returns

float `2**x`, computed element-wise.

Examples

```
>>> from scipy.special import exp2
```

```
>>> exp2(3)
8.0
>>> x = np.array([[-1, -0.5, 0], [0.5, 1, 1.5]])
>>> exp2(x)
array([[ 0.5       ,  0.70710678,  1.        ],
       [ 1.41421356,  2.        ,  2.82842712]])
```

scipy.special.radian

scipy.special.**radian**(*d*, *m*, *s*, *out=None*) **= <ufunc 'radian'>**

Convert from degrees to radians.

Returns the angle given in (d)egrees, (m)inutes, and (s)econds in radians.

Parameters

d [array_like] Degrees, can be real-valued.
m [array_like] Minutes, can be real-valued.
s [array_like] Seconds, can be real-valued.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Values of the inputs in radians.

Examples

```
>>> import scipy.special as sc
```

There are many ways to specify an angle.

```
>>> sc.radian(90, 0, 0)
1.5707963267948966
>>> sc.radian(0, 60 * 90, 0)
1.5707963267948966
```

(continues on next page)

(continued from previous page)

```
>>> sc.radian(0, 0, 60**2 * 90)
1.5707963267948966
```

The inputs can be real-valued.

```
>>> sc.radian(1.5, 0, 0)
0.02617993877991494
>>> sc.radian(1, 30, 0)
0.02617993877991494
```

scipy.special.cosdg

scipy.special.**cosdg**(*x*, *out=None*) **= <ufunc 'cosdg'>**

Cosine of the angle *x* given in degrees.

Parameters

x	[array_like] Angle, given in degrees.
out	[ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Cosine of the input.

See also:

sindg, **tandg**, **cotdg**

Examples

```
>>> import scipy.special as sc
```

It is more accurate than using cosine directly.

```
>>> x = 90 + 180 * np.arange(3)
>>> sc.cosdg(x)
array([-0.,  0., -0.])
>>> np.cos(x * np.pi / 180)
array([ 6.1232340e-17, -1.8369702e-16,  3.0616170e-16])
```

scipy.special.sindg

scipy.special.**sindg**(*x*, *out=None*) **= <ufunc 'sindg'>**

Sine of the angle *x* given in degrees.

Parameters

x	[array_like] Angle, given in degrees.
out	[ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Sine at the input.

See also:

cosdg, **tandg**, **cotdg**

Examples

```
>>> import scipy.special as sc
```

It is more accurate than using sine directly.

```
>>> x = 180 * np.arange(3)
>>> sc.sindg(x)
array([ 0., -0.,  0.])
>>> np.sin(x * np.pi / 180)
array([ 0.0000000e+00,  1.2246468e-16, -2.4492936e-16])
```

scipy.special.tandg

scipy.special.**tandg**(*x*, *out=None*) **= <ufunc 'tandg'>**
Tangent of angle *x* given in degrees.

Parameters

x [array_like] Angle, given in degrees.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Tangent at the input.

See also:

sindg, **cosdg**, **cotdg**

Examples

```
>>> import scipy.special as sc
```

It is more accurate than using tangent directly.

```
>>> x = 180 * np.arange(3)
>>> sc.tandg(x)
array([0., 0., 0.])
>>> np.tan(x * np.pi / 180)
array([ 0.0000000e+00, -1.2246468e-16, -2.4492936e-16])
```

scipy.special.cotdg

scipy.special.**cotdg**(*x*, *out=None*) **= <ufunc 'cotdg'>**

Cotangent of the angle *x* given in degrees.

Parameters

x [array_like] Angle, given in degrees.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Cotangent at the input.

See also:

sindg, **cosdg**, **tandg**

Examples

```
>>> import scipy.special as sc
```

It is more accurate than using cotangent directly.

```
>>> x = 90 + 180 * np.arange(3)
>>> sc.cotdg(x)
array([0., 0., 0.])
>>> 1 / np.tan(x * np.pi / 180)
array([6.1232340e-17, 1.8369702e-16, 3.0616170e-16])
```

scipy.special.log1p

scipy.special.**log1p**(*x*, *out=None*) **= <ufunc 'log1p'>**

Calculates log(1 + x) for use when *x* is near zero.

Parameters

x [array_like] Real or complex valued input.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Values of `log(1 + x)`.

See also:

expm1, **cosm1**

Examples

```
>>> import scipy.special as sc
```

It is more accurate than using `log(1 + x)` directly for `x` near 0. Note that in the below example `1 + 1e-17 == 1` to double precision.

```
>>> sc.log1p(1e-17)
1e-17
>>> np.log(1 + 1e-17)
0.0
```

scipy.special.expm1

scipy.special.**expm1**(*x*) **= <ufunc 'expm1'>**

Compute `exp(x) - 1`.

When *x* is near zero, `exp(x)` is near 1, so the numerical calculation of `exp(x) - 1` can suffer from catastrophic loss of precision. `expm1(x)` is implemented to avoid the loss of precision that occurs when *x* is near zero.

Parameters

x [array_like] *x* must contain real numbers.

Returns

float `exp(x) - 1` computed element-wise.

Examples

```
>>> from scipy.special import expm1
```

```
>>> expm1(1.0)
1.7182818284590451
>>> expm1([-0.2, -0.1, 0, 0.1, 0.2])
array([-0.18126925, -0.09516258,  0.        ,  0.10517092,  0.22140276])
```

The exact value of `exp(7.5e-13) - 1` is:

```
7.50000000000281250000000070312500000001318...*10**-13.
```

Here is what `expm1(7.5e-13)` gives:

```
>>> expm1(7.5e-13)
7.5000000000028135e-13
```

Compare that to `exp(7.5e-13) - 1`, where the subtraction results in a "catastrophic" loss of precision:

```
>>> np.exp(7.5e-13) - 1
7.5006667543675576e-13
```

scipy.special.cosm1

scipy.special.**cosm1**(*x*, *out=None*) **= <ufunc 'cosm1'>**

cos(x) - 1 for use when *x* is near zero.

Parameters

x [array_like] Real valued argument.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Values of `cos(x) - 1`.

See also:

expm1, **log1p**

Examples

```
>>> import scipy.special as sc
```

It is more accurate than computing `cos(x) - 1` directly for `x` around 0.

```
>>> x = 1e-30
>>> np.cos(x) - 1
0.0
>>> sc.cosm1(x)
-5.0000000000000005e-61
```

scipy.special.round

scipy.special.**round**(*x*, *out=None*) **= <ufunc 'round'>**

Round to the nearest integer.

Returns the nearest integer to *x*. If *x* ends in 0.5 exactly, the nearest even integer is chosen.

Parameters

x [array_like] Real valued input.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
The nearest integers to the elements of *x*. The result is of floating type, not integer type.

Examples

```
>>> import scipy.special as sc
```

It rounds to even.

```
>>> sc.round([0.5, 1.5])
array([0., 2.])
```

scipy.special.xlogy

scipy.special.**xlogy**(*x*, *y*) **= <ufunc 'xlogy'>**

Compute `x*log(y)` so that the result is 0 if `x = 0`.

Parameters

x	[array_like] Multiplier
y	[array_like] Argument

Returns

z	[array_like] Computed x*log(y)

Notes

New in version 0.13.0.

scipy.special.xlog1py

scipy.special.**xlog1py**(*x*, *y*) **= <ufunc 'xlog1py'>**

Compute `x*log1p(y)` so that the result is 0 if `x = 0`.

Parameters

x	[array_like] Multiplier
y	[array_like] Argument

Returns

z	[array_like] Computed x*log1p(y)

Notes

New in version 0.13.0.

scipy.special.logsumexp

scipy.special.**logsumexp**(*a*, *axis=None*, *b=None*, *keepdims=False*, *return_sign=False*)

Compute the log of the sum of exponentials of input elements.

Parameters

a [array_like] Input array.

axis [None or int or tuple of ints, optional] Axis or axes over which the sum is taken. By default *axis* is None, and all elements are summed.
New in version 0.11.0.

keepdims [bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array.
New in version 0.15.0.

b [array-like, optional] Scaling factor for exp(a) must be of the same shape as a or broadcastable to a. These values may be negative in order to implement subtraction.
New in version 0.12.0.

return_sign [bool, optional] If this is set to True, the result will be a pair containing sign information; if False, results that are negative will be returned as NaN. Default is False (no sign information).
New in version 0.16.0.

Returns

res [ndarray] The result, `np.log(np.sum(np.exp(a)))` calculated in a numerically more stable way. If *b* is given then `np.log(np.sum(b*np.exp(a)))` is returned.

sgn [ndarray] If return_sign is True, this will be an array of floating-point numbers matching res and +1, 0, or -1 depending on the sign of the result. If False, only one result is returned.

See also:

numpy.logaddexp*, *numpy.logaddexp2

Notes

NumPy has a logaddexp function which is very similar to *logsumexp*, but only handles two arguments. *logaddexp.reduce* is similar to this function, but may be less stable.

Examples

```
>>> from scipy.special import logsumexp
>>> a = np.arange(10)
>>> np.log(np.sum(np.exp(a)))
9.4586297444267107
>>> logsumexp(a)
9.4586297444267107
```

With weights

```
>>> a = np.arange(10)
>>> b = np.arange(10, 0, -1)
>>> logsumexp(a, b=b)
9.9170178533034665
```

(continues on next page)

(continued from previous page)

```
>>> np.log(np.sum(b*np.exp(a)))
9.9170178533034647
```

Returning a sign flag

```
>>> logsumexp([1,2],b=[1,-1],return_sign=True)
(1.5413248546129181, -1.0)
```

Notice that *logsumexp* does not directly support masked arrays. To use it on a masked array, convert the mask into zero weights:

```
>>> a = np.ma.array([np.log(2), 2, np.log(3)],
...                 mask=[False, True, False])
>>> b = (~a.mask).astype(int)
>>> logsumexp(a.data, b=b), np.log(5)
1.6094379124341005, 1.6094379124341005
```

scipy.special.exprel

scipy.special.**exprel**(*x*) **= <ufunc 'exprel'>**

Relative error exponential, `(exp(x) - 1)/x`.

When *x* is near zero, `exp(x)` is near 1, so the numerical calculation of `exp(x) - 1` can suffer from catastrophic loss of precision. `exprel(x)` is implemented to avoid the loss of precision that occurs when *x* is near zero.

Parameters

x [ndarray] Input array. *x* must contain real numbers.

Returns

float `(exp(x) - 1)/x`, computed element-wise.

See also:

expm1

Notes

New in version 0.17.0.

Examples

```
>>> from scipy.special import exprel
```

```
>>> exprel(0.01)
1.0050167084168056
>>> exprel([-0.25, -0.1, 0, 0.1, 0.25])
array([ 0.88479687,  0.95162582,  1.        ,  1.05170918,  1.13610167])
```

Compare `exprel(5e-9)` to the naive calculation. The exact value is `1.0000000250000000416...`.

```
>>> exprel(5e-9)
1.0000000025
```

```
>>> (np.exp(5e-9) - 1)/5e-9
0.99999999392252903
```

scipy.special.sinc

scipy.special.**sinc**(x)

Return the normalized sinc function.

The sinc function is $\sin(\pi x)/(\pi x)$.

Note: Note the normalization factor of `pi` used in the definition. This is the most commonly used definition in signal processing. Use `sinc(x / np.pi)` to obtain the unnormalized sinc function $\sin(x)/(x)$ that is more common in mathematics.

Parameters

x [ndarray] Array (possibly multi-dimensional) of values for which to to calculate `sinc(x)`.

Returns

out [ndarray] `sinc(x)`, which has the same shape as the input.

Notes

`sinc(0)` is the limit value 1.

The name sinc is short for "sine cardinal" or "sinus cardinalis".

The sinc function is used in various signal processing applications, including in anti-aliasing, in the construction of a Lanczos resampling filter, and in interpolation.

For bandlimited interpolation of discrete-time signals, the ideal interpolation kernel is proportional to the sinc function.

3.3.29 Statistical functions (`scipy.stats`)

This module contains a large number of probability distributions, summary and frequency statistics, correlation functions and statistical tests, masked statistics, kernel density estimation, quasi-Monte Carlo functionality, and more.

Statistics is a very large area, and there are topics that are out of scope for SciPy and are covered by other packages. Some of the most important ones are:

- statsmodels: regression, linear models, time series analysis, extensions to topics also covered by `scipy.stats`.
- Pandas: tabular data, time series functionality, interfaces to other statistical languages.
- PyMC3: Bayesian statistical modeling, probabilistic machine learning.

- scikit-learn: classification, regression, model selection.
- Seaborn: statistical data visualization.
- rpy2: Python to R bridge.

Probability distributions

Each univariate distribution is an instance of a subclass of *rv_continuous* (*rv_discrete* for discrete distributions):

rv_continuous([momtype, a, b, xtol, …])	A generic continuous random variable class meant for subclassing.
rv_discrete([a, b, name, badvalue, …])	A generic discrete random variable class meant for subclassing.
rv_histogram(histogram, *args, **kwargs)	Generates a distribution given by a histogram.

scipy.stats.rv_continuous

class scipy.stats.**rv_continuous**(*momtype=1*, *a=None*, *b=None*, *xtol=1e-14*, *badvalue=None*, *name=None*, *longname=None*, *shapes=None*, *extradoc=None*, *seed=None*)

A generic continuous random variable class meant for subclassing.

rv_continuous is a base class to construct specific distribution classes and instances for continuous random variables. It cannot be used directly as a distribution.

Parameters

momtype [int, optional] The type of generic moment calculation to use: 0 for pdf, 1 (default) for ppf.

a [float, optional] Lower bound of the support of the distribution, default is minus infinity.

b [float, optional] Upper bound of the support of the distribution, default is plus infinity.

xtol [float, optional] The tolerance for fixed point calculation for generic ppf.

badvalue [float, optional] The value in a result arrays that indicates a value that for which some argument restriction is violated, default is np.nan.

name [str, optional] The name of the instance. This string is used to construct the default example for distributions.

longname [str, optional] This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: *longname* exists for backwards compatibility, do not use for new subclasses.

shapes [str, optional] The shape of the distribution. For example `"m, n"` for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signature of the private methods, `_pdf` and `_cdf` of the instance.

extradoc [str, optional, deprecated] This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: *extradoc* exists for backwards compatibility, do not use for new subclasses.

seed [{None, int, `numpy.random.Generator`,] `numpy.random.RandomState`}, optional
If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Notes

Public methods of an instance of a distribution class (e.g., pdf, cdf) check their arguments and pass valid arguments to private, computational methods (_pdf, _cdf). For pdf(x), x is valid if it is within the support of the distribution. Whether a shape parameter is valid is decided by an _argcheck method (which defaults to checking that its arguments are strictly positive.)

Subclassing

New random variables can be defined by subclassing the *rv_continuous* class and re-defining at least the _pdf or the _cdf method (normalized to location 0 and scale 1).

If positive argument checking is not correct for your RV then you will also need to re-define the _argcheck method.

For most of the scipy.stats distributions, the support interval doesn't depend on the shape parameters. x being in the support interval is equivalent to self.a <= x <= self.b. If either of the endpoints of the support do depend on the shape parameters, then i) the distribution must implement the _get_support method; and ii) those dependent endpoints must be omitted from the distribution's call to the rv_continuous initializer.

Correct, but potentially slow defaults exist for the remaining methods but for speed and/or accuracy you can override:

```
_logpdf, _cdf, _logcdf, _ppf, _rvs, _isf, _sf, _logsf
```

The default method _rvs relies on the inverse of the cdf, _ppf, applied to a uniform random variate. In order to generate random variates efficiently, either the default _ppf needs to be overwritten (e.g. if the inverse cdf can expressed in an explicit form) or a sampling method needs to be implemented in a custom _rvs method.

If possible, you should override _isf, _sf or _logsf. The main reason would be to improve numerical accuracy: for example, the survival function _sf is computed as 1 - _cdf which can result in loss of precision if _cdf(x) is close to one.

Methods that can be overwritten by subclasses

```
_rvs
_pdf
_cdf
_sf
_ppf
_isf
_stats
_munp
_entropy
_argcheck
_get_support
```

There are additional (internal and private) generic methods that can be useful for cross-checking and for debugging, but might work in all cases when directly called.

A note on shapes: subclasses need not specify them explicitly. In this case, *shapes* will be automatically deduced from the signatures of the overridden methods (*pdf*, *cdf* etc). If, for some reason, you prefer to avoid relying on introspection, you can specify shapes explicitly as an argument to the instance constructor.

Frozen Distributions

Normally, you must provide shape parameters (and, optionally, location and scale parameters to each call of a method of a distribution.

Alternatively, the object may be called (as a function) to fix the shape, location, and scale parameters returning a "frozen" continuous RV object:

rv = generic(<shape(s)>, loc=0, scale=1)

rv_frozen object with the same methods but holding the given shape, location, and scale fixed

Statistics

Statistics are computed using numerical integration by default. For speed you can redefine this using `_stats`:

- take shape parameters and return mu, mu2, g1, g2
- If you can't compute one of these, return it as None
- Can also be defined with a keyword argument `moments`, which is a string composed of "m", "v", "s", and/or "k". Only the components appearing in string should be computed and returned in the order "m", "v", "s", or "k" with missing values returned as None.

Alternatively, you can override `_munp`, which takes `n` and shape parameters and returns the n-th non-central moment of the distribution.

Examples

To create a new Gaussian distribution, we would do the following:

```
>>> from scipy.stats import rv_continuous
>>> class gaussian_gen(rv_continuous):
...     "Gaussian distribution"
...     def _pdf(self, x):
...         return np.exp(-x**2 / 2.) / np.sqrt(2.0 * np.pi)
>>> gaussian = gaussian_gen(name='gaussian')
```

`scipy.stats` distributions are *instances*, so here we subclass *rv_continuous* and create an instance. With this, we now have a fully functional distribution with all relevant methods automagically generated by the framework.

Note that above we defined a standard normal distribution, with zero mean and unit variance. Shifting and scaling of the distribution can be done by using `loc` and `scale` parameters: `gaussian.pdf(x, loc, scale)` essentially computes `y = (x - loc) / scale` and `gaussian._pdf(y) / scale`.

Attributes

random_state
: Get or set the generator object for generating random variates.

Methods

rvs(*args, **kwds)	Random variates of given type.
pdf(x, *args, **kwds)	Probability density function at x of the given RV.
logpdf(x, *args, **kwds)	Log of the probability density function at x of the given RV.
cdf(x, *args, **kwds)	Cumulative distribution function of the given RV.
logcdf(x, *args, **kwds)	Log of the cumulative distribution function at x of the given RV.
sf(x, *args, **kwds)	Survival function (1 - *cdf*) at x of the given RV.
logsf(x, *args, **kwds)	Log of the survival function of the given RV.

continues on next page

Table 257 – continued from previous page

ppf(q, *args, **kwds)	Percent point function (inverse of *cdf*) at q of the given RV.
isf(q, *args, **kwds)	Inverse survival function (inverse of *sf*) at q of the given RV.
moment(n, *args, **kwds)	n-th order non-central moment of distribution.
stats(*args, **kwds)	Some statistics of the given RV.
entropy(*args, **kwds)	Differential entropy of the RV.
expect([func, args, loc, scale, lb, ub, …])	Calculate expected value of a function with respect to the distribution by numerical integration.
median(*args, **kwds)	Median of the distribution.
mean(*args, **kwds)	Mean of the distribution.
std(*args, **kwds)	Standard deviation of the distribution.
var(*args, **kwds)	Variance of the distribution.
interval(alpha, *args, **kwds)	Confidence interval with equal areas around the median.
__call__(*args, **kwds)	Freeze the distribution for the given arguments.
fit(data, *args, **kwds)	Return estimates of shape (if applicable), location, and scale parameters from data.
fit_loc_scale(data, *args)	Estimate loc and scale parameters from data using 1st and 2nd moments.
nnlf(theta, x)	Negative loglikelihood function.
support(*args, **kwargs)	Support of the distribution.

scipy.stats.rv_continuous.rvs

rv_continuous.**rvs**(**args*, ***kwds*)

Random variates of given type.

Parameters

arg1, arg2, arg3,…
: [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc
: [array_like, optional] Location parameter (default=0).

scale
: [array_like, optional] Scale parameter (default=1).

size
: [int or tuple of ints, optional] Defining number of random variates (default is 1).

random_state
: [{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional
If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Returns

rvs
: [ndarray or scalar] Random variates of given *size*.

scipy.stats.rv_continuous.pdf

rv_continuous.**pdf**(*x*, **args*, ***kwds*)
Probability density function at x of the given RV.

Parameters

x [array_like] quantiles
arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

pdf [ndarray] Probability density function evaluated at x

scipy.stats.rv_continuous.logpdf

rv_continuous.**logpdf**(*x*, **args*, ***kwds*)
Log of the probability density function at x of the given RV.

This uses a more numerically accurate calculation if available.

Parameters

x [array_like] quantiles
arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

logpdf [array_like] Log of the probability density function evaluated at x

scipy.stats.rv_continuous.cdf

rv_continuous.**cdf**(*x*, **args*, ***kwds*)
Cumulative distribution function of the given RV.

Parameters

x [array_like] quantiles
arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

cdf [ndarray] Cumulative distribution function evaluated at *x*

scipy.stats.rv_continuous.logcdf

rv_continuous.**logcdf**(*x*, **args*, ***kwds*)

Log of the cumulative distribution function at x of the given RV.

Parameters

x [array_like] quantiles

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

logcdf [array_like] Log of the cumulative distribution function evaluated at x

scipy.stats.rv_continuous.sf

rv_continuous.**sf**(*x*, **args*, ***kwds*)

Survival function (1 - *cdf*) at x of the given RV.

Parameters

x [array_like] quantiles

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

sf [array_like] Survival function evaluated at x

scipy.stats.rv_continuous.logsf

rv_continuous.**logsf**(*x*, **args*, ***kwds*)

Log of the survival function of the given RV.

Returns the log of the "survival function," defined as (1 - *cdf*), evaluated at *x*.

Parameters

x [array_like] quantiles

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

logsf [ndarray] Log of the survival function evaluated at *x*.

scipy.stats.rv_continuous.ppf

rv_continuous.**ppf**(*q*, **args*, ***kwds*)
Percent point function (inverse of *cdf*) at q of the given RV.

Parameters

q [array_like] lower tail probability
arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

x [array_like] quantile corresponding to the lower tail probability q.

scipy.stats.rv_continuous.isf

rv_continuous.**isf**(*q*, **args*, ***kwds*)
Inverse survival function (inverse of *sf*) at q of the given RV.

Parameters

q [array_like] upper tail probability
arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

x [ndarray or scalar] Quantile corresponding to the upper tail probability q.

scipy.stats.rv_continuous.moment

rv_continuous.**moment**(*n*, **args*, ***kwds*)
n-th order non-central moment of distribution.

Parameters

n [int, n >= 1] Order of moment.
arg1, arg2, arg3,… [float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

scipy.stats.rv_continuous.stats

rv_continuous.**stats**(**args*, ***kwds*)

Some statistics of the given RV.

Parameters

arg1, arg2, arg3,…
: [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc
: [array_like, optional] location parameter (default=0)

scale
: [array_like, optional (continuous RVs only)] scale parameter (default=1)

moments
: [str, optional] composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

Returns

stats
: [sequence] of requested moments.

scipy.stats.rv_continuous.entropy

rv_continuous.**entropy**(**args*, ***kwds*)

Differential entropy of the RV.

Parameters

arg1, arg2, arg3,…
: [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc
: [array_like, optional] Location parameter (default=0).

scale
: [array_like, optional (continuous distributions only).] Scale parameter (default=1).

Notes

Entropy is defined base *e*:

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

scipy.stats.rv_continuous.expect

rv_continuous.**expect**(*func=None*, *args=()*, *loc=0*, *scale=1*, *lb=None*, *ub=None*, *conditional=False*, ***kwds*)

Calculate expected value of a function with respect to the distribution by numerical integration.

The expected value of a function `f(x)` with respect to a distribution `dist` is defined as:

```
        ub
E[f(x)] = Integral(f(x) * dist.pdf(x)),
        lb
```

where `ub` and `lb` are arguments and `x` has the `dist.pdf(x)` distribution. If the bounds `lb` and `ub` correspond to the support of the distribution, e.g. `[-inf, inf]` in the default case, then the integral is the unrestricted expectation of `f(x)`. Also, the function `f(x)` may be defined such that `f(x)` is `0` outside a finite interval in which case the expectation is calculated within the finite range `[lb, ub]`.

Parameters

func [callable, optional] Function for which integral is calculated. Takes only one argument. The default is the identity mapping f(x) = x.

args [tuple, optional] Shape parameters of the distribution.

loc [float, optional] Location parameter (default=0).

scale [float, optional] Scale parameter (default=1).

lb, ub [scalar, optional] Lower and upper bound for integration. Default is set to the support of the distribution.

conditional [bool, optional] If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.

Additional keyword arguments are passed to the integration routine.

Returns

expect [float] The calculated expected value.

Notes

The integration behavior of this function is inherited from *scipy.integrate.quad*. Neither this function nor *scipy.integrate.quad* can verify whether the integral exists or is finite. For example `cauchy(0).mean()` returns `np.nan` and `cauchy(0).expect()` returns `0.0`.

The function is not vectorized.

Examples

To understand the effect of the bounds of integration consider

```
>>> from scipy.stats import expon
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0)
0.6321205588285578
```

This is close to

```
>>> expon(1).cdf(2.0) - expon(1).cdf(0.0)
0.6321205588285577
```

If `conditional=True`

```
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0, conditional=True)
1.0000000000000002
```

The slight deviation from 1 is due to numerical integration.

scipy.stats.rv_continuous.median

rv_continuous.**median**(**args*, ***kwds*)

Median of the distribution.

Parameters

arg1, arg2, arg3,…
: [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc
: [array_like, optional] Location parameter, Default is 0.

scale
: [array_like, optional] Scale parameter, Default is 1.

Returns

median
: [float] The median of the distribution.

See also:

rv_discrete.ppf
: Inverse of the CDF

scipy.stats.rv_continuous.mean

rv_continuous.**mean**(**args*, ***kwds*)

Mean of the distribution.

Parameters

arg1, arg2, arg3,…
: [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc
: [array_like, optional] location parameter (default=0)

scale
: [array_like, optional] scale parameter (default=1)

Returns

mean
: [float] the mean of the distribution

scipy.stats.rv_continuous.std

rv_continuous.**std**(**args*, ***kwds*)

Standard deviation of the distribution.

Parameters

arg1, arg2, arg3,…
: [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc
: [array_like, optional] location parameter (default=0)

scale
: [array_like, optional] scale parameter (default=1)

Returns

std
: [float] standard deviation of the distribution

scipy.stats.rv_continuous.var

rv_continuous.**var**(**args*, ***kwds*)
Variance of the distribution.

Parameters

arg1, arg2, arg3,…
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

var [float] the variance of the distribution

scipy.stats.rv_continuous.interval

rv_continuous.**interval**(*alpha*, **args*, ***kwds*)
Confidence interval with equal areas around the median.

Parameters

alpha [array_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].
arg1, arg2, …
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] location parameter, Default is 0.
scale [array_like, optional] scale parameter, Default is 1.

Returns

a, b [ndarray of float] end-points of range that contain `100 * alpha %` of the rv's possible values.

scipy.stats.rv_continuous.__call__

rv_continuous.**__call__**(**args*, ***kwds*)
Freeze the distribution for the given arguments.

Parameters

arg1, arg2, arg3,…
[array_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

Returns

rv_frozen [rv_frozen instance] The frozen distribution.

scipy.stats.rv_continuous.fit

rv_continuous.**fit**(*data*, **args*, ***kwds*)

Return estimates of shape (if applicable), location, and scale parameters from data. The default estimation method is Maximum Likelihood Estimation (MLE), but Method of Moments (MM) is also available.

Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, `self._fitstart(data)` is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments `f0`, `f1`, …, `fn` (for shape parameters) and `floc` and `fscale` (for location and scale parameters, respectively).

Parameters

data [array_like] Data to use in estimating the distribution parameters.

arg1, arg2, arg3,…
[floats, optional] Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to `_fitstart(data)`). No default value.

kwds [floats, optional]
- *loc*: initial guess of the distribution's location parameter.
- *scale*: initial guess of the distribution's scale parameter.

Special keyword arguments are recognized as holding certain parameters fixed:
- f0…fn : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fa` and `fix_a` are equivalent to `f0`, and `fb` and `fix_b` are equivalent to `f1`.
- floc : hold location parameter fixed to specified value.
- fscale : hold scale parameter fixed to specified value.
- optimizer : The optimizer to use. The optimizer must take `func`, and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.
- method : The method to use. The default is "MLE" (Maximum Likelihood Estimate); "MM" (Method of Moments) is also available.

Returns

parameter_tuple
[tuple of floats] Estimates for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

Notes

With `method="MLE"` (default), the fit is computed by minimizing the negative log-likelihood function. A large, finite penalty (rather than infinite negative log-likelihood) is applied for observations beyond the support of the distribution.

With `method="MM"`, the fit is computed by minimizing the L2 norm of the relative errors between the first *k* raw (about zero) data moments and the corresponding distribution moments, where *k* is the number of non-fixed parameters. More precisely, the objective function is:

```
(((data_moments - dist_moments)
  / np.maximum(np.abs(data_moments), 1e-8))**2).sum()
```

where the constant `1e-8` avoids division by zero in case of vanishing data moments. Typically, this error norm can be reduced to zero. Note that the standard method of moments can produce parameters for which some data are outside the support of the fitted distribution; this implementation does nothing to prevent this.

For either method, the returned answer is not guaranteed to be globally optimal; it may only be locally optimal, or the optimization may fail altogether. If the data contain any of `np.nan`, `np.inf`, or `-np.inf`, the *fit* method will raise a `RuntimeError`.

Examples

Generate some data to fit: draw random variates from the *beta* distribution

```
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (`a`, `b`, `loc` and `scale`):

```
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let's keep `loc` and `scale` fixed:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using `f`-keywords. To keep the zero-th shape parameter `a` equal 1, use `f0=1` or, equivalently, `fa=1`:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. `norm` for example just returns estimates for location and scale:

```
>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```

scipy.stats.rv_continuous.fit_loc_scale

`rv_continuous.`**`fit_loc_scale`**(*data*, **args*)

Estimate loc and scale parameters from data using 1st and 2nd moments.

Parameters

data [array_like] Data to fit.

arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

Returns

Lhat [float] Estimated location parameter for the data.

Shat [float] Estimated scale parameter for the data.

scipy.stats.rv_continuous.nnlf

rv_continuous.**nnlf**(*theta*, *x*)
Negative loglikelihood function.

Notes

This is `-sum(log pdf(x, theta), axis=0)` where *theta* are the parameters (including loc and scale).

scipy.stats.rv_continuous.support

rv_continuous.**support**(**args*, ***kwargs*)
Support of the distribution.

Parameters

arg1, arg2, …
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] location parameter, Default is 0.
scale [array_like, optional] scale parameter, Default is 1.

Returns

a, b [array_like] end-points of the distribution's support.

scipy.stats.rv_discrete

class scipy.stats.**rv_discrete**(*a=0*, *b=inf*, *name=None*, *badvalue=None*, *moment_tol=1e-08*, *values=None*, *inc=1*, *longname=None*, *shapes=None*, *extradoc=None*, *seed=None*)
A generic discrete random variable class meant for subclassing.

rv_discrete is a base class to construct specific distribution classes and instances for discrete random variables. It can also be used to construct an arbitrary distribution defined by a list of support points and corresponding probabilities.

Parameters

a [float, optional] Lower bound of the support of the distribution, default: 0
b [float, optional] Upper bound of the support of the distribution, default: plus infinity
moment_tol
[float, optional] The tolerance for the generic calculation of moments.
values [tuple of two array_like, optional] `(xk, pk)` where `xk` are integers and `pk` are the non-zero probabilities between 0 and 1 with `sum(pk) = 1`. `xk` and `pk` must have the same shape.
inc [integer, optional] Increment for the support of the distribution. Default is 1. (other values have not been tested)
badvalue [float, optional] The value in a result arrays that indicates a value that for which some argument restriction is violated, default is np.nan.
name [str, optional] The name of the instance. This string is used to construct the default example for distributions.
longname [str, optional] This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: *longname* exists for backwards compatibility, do not use for new subclasses.

shapes [str, optional] The shape of the distribution. For example "m, n" for a distribution that takes two integers as the two shape arguments for all its methods If not provided, shape parameters will be inferred from the signatures of the private methods, `_pmf` and `_cdf` of the instance.

extradoc [str, optional] This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: *extradoc* exists for backwards compatibility, do not use for new subclasses.

seed [{None, int, `numpy.random.Generator`,] `numpy.random.RandomState`}, optional
If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Notes

This class is similar to *rv_continuous*. Whether a shape parameter is valid is decided by an `_argcheck` method (which defaults to checking that its arguments are strictly positive.) The main differences are:

- the support of the distribution is a set of integers
- instead of the probability density function, `pdf` (and the corresponding private `_pdf`), this class defines the *probability mass function*, *pmf* (and the corresponding private `_pmf`.)
- scale parameter is not defined.

To create a new discrete distribution, we would do the following:

```
>>> from scipy.stats import rv_discrete
>>> class poisson_gen(rv_discrete):
...     "Poisson distribution"
...     def _pmf(self, k, mu):
...         return exp(-mu) * mu**k / factorial(k)
```

and create an instance:

```
>>> poisson = poisson_gen(name="poisson")
```

Note that above we defined the Poisson distribution in the standard form. Shifting the distribution can be done by providing the `loc` parameter to the methods of the instance. For example, `poisson.pmf(x, mu, loc)` delegates the work to `poisson._pmf(x-loc, mu)`.

Discrete distributions from a list of probabilities

Alternatively, you can construct an arbitrary discrete rv defined on a finite set of values `xk` with `Prob{X=xk} = pk` by using the `values` keyword argument to the *rv_discrete* constructor.

Examples

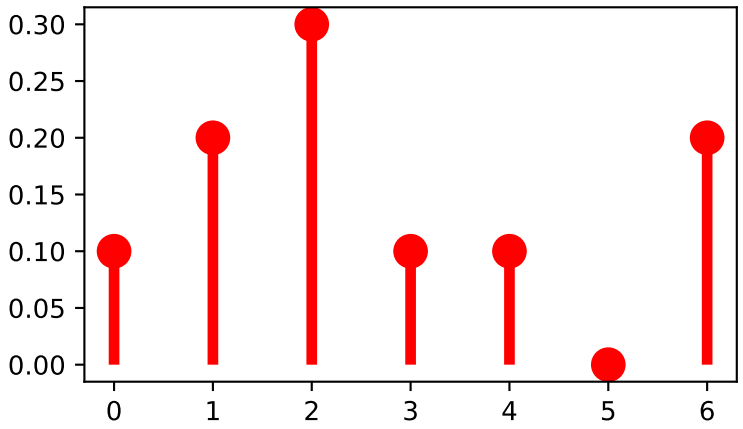
Custom made discrete distribution:

```
>>> from scipy import stats
>>> xk = np.arange(7)
>>> pk = (0.1, 0.2, 0.3, 0.1, 0.1, 0.0, 0.2)
>>> custm = stats.rv_discrete(name='custm', values=(xk, pk))
>>>
>>> import matplotlib.pyplot as plt
```

(continues on next page)

(continued from previous page)

```
>>> fig, ax = plt.subplots(1, 1)
>>> ax.plot(xk, custm.pmf(xk), 'ro', ms=12, mec='r')
>>> ax.vlines(xk, 0, custm.pmf(xk), colors='r', lw=4)
>>> plt.show()
```



Random number generation:

```
>>> R = custm.rvs(size=100)
```

Attributes

random_state
Get or set the generator object for generating random variates.

Methods

rvs(*args, **kwargs)	Random variates of given type.
pmf(k, *args, **kwds)	Probability mass function at k of the given RV.
logpmf(k, *args, **kwds)	Log of the probability mass function at k of the given RV.
cdf(k, *args, **kwds)	Cumulative distribution function of the given RV.
logcdf(k, *args, **kwds)	Log of the cumulative distribution function at k of the given RV.
sf(k, *args, **kwds)	Survival function (1 - *cdf*) at k of the given RV.
logsf(k, *args, **kwds)	Log of the survival function of the given RV.
ppf(q, *args, **kwds)	Percent point function (inverse of *cdf*) at q of the given RV.
isf(q, *args, **kwds)	Inverse survival function (inverse of *sf*) at q of the given RV.
moment(n, *args, **kwds)	n-th order non-central moment of distribution.
stats(*args, **kwds)	Some statistics of the given RV.

continues on next page

Table 258 – continued from previous page

entropy(*args, **kwds)	Differential entropy of the RV.
expect([func, args, loc, lb, ub, …])	Calculate expected value of a function with respect to the distribution for discrete distribution by numerical summation.
median(*args, **kwds)	Median of the distribution.
mean(*args, **kwds)	Mean of the distribution.
std(*args, **kwds)	Standard deviation of the distribution.
var(*args, **kwds)	Variance of the distribution.
interval(alpha, *args, **kwds)	Confidence interval with equal areas around the median.
__call__(*args, **kwds)	Freeze the distribution for the given arguments.
support(*args, **kwargs)	Support of the distribution.

scipy.stats.rv_discrete.rvs

rv_discrete.**rvs**(**args*, ***kwargs*)

Random variates of given type.

Parameters

arg1, arg2, arg3,…
: [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc
: [array_like, optional] Location parameter (default=0).

size
: [int or tuple of ints, optional] Defining number of random variates (Default is 1). Note that *size* has to be given as keyword, not as positional argument.

random_state
: [{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional
If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Returns

rvs
: [ndarray or scalar] Random variates of given *size*.

scipy.stats.rv_discrete.pmf

rv_discrete.**pmf**(*k*, **args*, ***kwds*)

Probability mass function at k of the given RV.

Parameters

k
: [array_like] Quantiles.

arg1, arg2, arg3,…
: [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc
: [array_like, optional] Location parameter (default=0).

Returns

pmf
: [array_like] Probability mass function evaluated at k

scipy.stats.rv_discrete.logpmf

rv_discrete.**logpmf**(*k*, **args*, ***kwds*)

Log of the probability mass function at k of the given RV.

Parameters

k [array_like] Quantiles.

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] Location parameter. Default is 0.

Returns

logpmf [array_like] Log of the probability mass function evaluated at k.

scipy.stats.rv_discrete.cdf

rv_discrete.**cdf**(*k*, **args*, ***kwds*)

Cumulative distribution function of the given RV.

Parameters

k [array_like, int] Quantiles.

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] Location parameter (default=0).

Returns

cdf [ndarray] Cumulative distribution function evaluated at *k*.

scipy.stats.rv_discrete.logcdf

rv_discrete.**logcdf**(*k*, **args*, ***kwds*)

Log of the cumulative distribution function at k of the given RV.

Parameters

k [array_like, int] Quantiles.

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] Location parameter (default=0).

Returns

logcdf [array_like] Log of the cumulative distribution function evaluated at k.

scipy.stats.rv_discrete.sf

rv_discrete.**sf**(*k*, **args*, ***kwds*)
Survival function (1 - *cdf*) at k of the given RV.

Parameters

k [array_like] Quantiles.
arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] Location parameter (default=0).

Returns

sf [array_like] Survival function evaluated at k.

scipy.stats.rv_discrete.logsf

rv_discrete.**logsf**(*k*, **args*, ***kwds*)
Log of the survival function of the given RV.

Returns the log of the "survival function," defined as 1 - *cdf*, evaluated at *k*.

Parameters

k [array_like] Quantiles.
arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] Location parameter (default=0).

Returns

logsf [ndarray] Log of the survival function evaluated at *k*.

scipy.stats.rv_discrete.ppf

rv_discrete.**ppf**(*q*, **args*, ***kwds*)
Percent point function (inverse of *cdf*) at q of the given RV.

Parameters

q [array_like] Lower tail probability.
arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] Location parameter (default=0).

Returns

k [array_like] Quantile corresponding to the lower tail probability, q.

scipy.stats.rv_discrete.isf

rv_discrete.**isf**(*q*, **args*, ***kwds*)

Inverse survival function (inverse of *sf*) at q of the given RV.

Parameters

q [array_like] Upper tail probability.

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] Location parameter (default=0).

Returns

k [ndarray or scalar] Quantile corresponding to the upper tail probability, q.

scipy.stats.rv_discrete.moment

rv_discrete.**moment**(*n*, **args*, ***kwds*)

n-th order non-central moment of distribution.

Parameters

n [int, n >= 1] Order of moment.

arg1, arg2, arg3,… [float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

scipy.stats.rv_discrete.stats

rv_discrete.**stats**(**args*, ***kwds*)

Some statistics of the given RV.

Parameters

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional (continuous RVs only)] scale parameter (default=1)

moments [str, optional] composed of letters [‘mvsk’] defining which moments to compute: ‘m’ = mean, ‘v’ = variance, ‘s’ = (Fisher’s) skew, ‘k’ = (Fisher’s) kurtosis. (default is ‘mv’)

Returns

stats [sequence] of requested moments.

scipy.stats.rv_discrete.entropy

rv_discrete.**entropy**(**args*, ***kwds*)

Differential entropy of the RV.

Parameters

arg1, arg2, arg3,…
: [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc
: [array_like, optional] Location parameter (default=0).

scale
: [array_like, optional (continuous distributions only).] Scale parameter (default=1).

Notes

Entropy is defined base *e*:

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

scipy.stats.rv_discrete.expect

rv_discrete.**expect**(*func=None*, *args=()*, *loc=0*, *lb=None*, *ub=None*, *conditional=False*, *maxcount=1000*, *tolerance=1e-10*, *chunksize=32*)

Calculate expected value of a function with respect to the distribution for discrete distribution by numerical summation.

Parameters

func
: [callable, optional] Function for which the expectation value is calculated. Takes only one argument. The default is the identity mapping f(k) = k.

args
: [tuple, optional] Shape parameters of the distribution.

loc
: [float, optional] Location parameter. Default is 0.

lb, ub
: [int, optional] Lower and upper bound for the summation, default is set to the support of the distribution, inclusive (`lb <= k <= ub`).

conditional
: [bool, optional] If true then the expectation is corrected by the conditional probability of the summation interval. The return value is the expectation of the function, *func*, conditional on being in the given interval (k such that `lb <= k <= ub`). Default is False.

maxcount
: [int, optional] Maximal number of terms to evaluate (to avoid an endless loop for an infinite sum). Default is 1000.

tolerance
: [float, optional] Absolute tolerance for the summation. Default is 1e-10.

chunksize
: [int, optional] Iterate over the support of a distributions in chunks of this size. Default is 32.

Returns

expect
: [float] Expected value.

Notes

For heavy-tailed distributions, the expected value may or may not exist, depending on the function, *func*. If it does exist, but the sum converges slowly, the accuracy of the result may be rather low. For instance, for `zipf(4)`, accuracy for mean, variance in example is only 1e-5. increasing *maxcount* and/or *chunksize* may improve the result, but may also make zipf very slow.

The function is not vectorized.

scipy.stats.rv_discrete.median

`rv_discrete.`**`median`**`(*args, **kwds)`

Median of the distribution.

Parameters

arg1, arg2, arg3,…
: [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc
: [array_like, optional] Location parameter, Default is 0.

scale
: [array_like, optional] Scale parameter, Default is 1.

Returns

median
: [float] The median of the distribution.

See also:

`rv_discrete.ppf`

Inverse of the CDF

scipy.stats.rv_discrete.mean

`rv_discrete.`**`mean`**`(*args, **kwds)`

Mean of the distribution.

Parameters

arg1, arg2, arg3,…
: [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc
: [array_like, optional] location parameter (default=0)

scale
: [array_like, optional] scale parameter (default=1)

Returns

mean
: [float] the mean of the distribution

scipy.stats.rv_discrete.std

rv_discrete.**std**(**args*, ***kwds*)
Standard deviation of the distribution.

Parameters

arg1, arg2, arg3,…
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

std [float] standard deviation of the distribution

scipy.stats.rv_discrete.var

rv_discrete.**var**(**args*, ***kwds*)
Variance of the distribution.

Parameters

arg1, arg2, arg3,…
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

var [float] the variance of the distribution

scipy.stats.rv_discrete.interval

rv_discrete.**interval**(*alpha*, **args*, ***kwds*)
Confidence interval with equal areas around the median.

Parameters

alpha [array_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].
arg1, arg2, …
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] location parameter, Default is 0.
scale [array_like, optional] scale parameter, Default is 1.

Returns

a, b [ndarray of float] end-points of range that contain `100 * alpha %` of the rv's possible values.

scipy.stats.rv_discrete.__call__

rv_discrete.**__call__**(**args*, ***kwds*)
Freeze the distribution for the given arguments.

Parameters

arg1, arg2, arg3,…
[array_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

Returns

rv_frozen [rv_frozen instance] The frozen distribution.

scipy.stats.rv_discrete.support

rv_discrete.**support**(**args*, ***kwargs*)
Support of the distribution.

Parameters

arg1, arg2, …
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] location parameter, Default is 0.
scale [array_like, optional] scale parameter, Default is 1.

Returns

a, b [array_like] end-points of the distribution's support.

scipy.stats.rv_histogram

class scipy.stats.**rv_histogram**(*histogram*, **args*, ***kwargs*)
Generates a distribution given by a histogram. This is useful to generate a template distribution from a binned datasample.

As a subclass of the *rv_continuous* class, *rv_histogram* inherits from it a collection of generic methods (see *rv_continuous* for the full list), and implements them based on the properties of the provided binned datasample.

Parameters

histogram [tuple of array_like] Tuple containing two array_like objects The first containing the content of n bins The second containing the (n+1) bin boundaries In particular the return value np.histogram is accepted

Notes

There are no additional shape parameters except for the loc and scale. The pdf is defined as a stepwise function from the provided histogram The cdf is a linear interpolation of the pdf.

New in version 0.19.0.

Examples

Create a scipy.stats distribution from a numpy histogram

```
>>> import scipy.stats
>>> import numpy as np
>>> data = scipy.stats.norm.rvs(size=100000, loc=0, scale=1.5, random_
↪state=123)
>>> hist = np.histogram(data, bins=100)
>>> hist_dist = scipy.stats.rv_histogram(hist)
```

Behaves like an ordinary scipy rv_continuous distribution

```
>>> hist_dist.pdf(1.0)
0.20538577847618705
>>> hist_dist.cdf(2.0)
0.90818568543056499
```

PDF is zero above (below) the highest (lowest) bin of the histogram, defined by the max (min) of the original dataset

```
>>> hist_dist.pdf(np.max(data))
0.0
>>> hist_dist.cdf(np.max(data))
1.0
>>> hist_dist.pdf(np.min(data))
7.7591907244498314e-05
>>> hist_dist.cdf(np.min(data))
0.0
```

PDF and CDF follow the histogram

```
>>> import matplotlib.pyplot as plt
>>> X = np.linspace(-5.0, 5.0, 100)
>>> plt.title("PDF from Template")
>>> plt.hist(data, density=True, bins=100)
>>> plt.plot(X, hist_dist.pdf(X), label='PDF')
>>> plt.plot(X, hist_dist.cdf(X), label='CDF')
>>> plt.show()
```

Attributes

random_state
: Get or set the generator object for generating random variates.

Methods

__call__(*args, **kwds)	Freeze the distribution for the given arguments.
cdf(x, *args, **kwds)	Cumulative distribution function of the given RV.
entropy(*args, **kwds)	Differential entropy of the RV.
expect([func, args, loc, scale, lb, ub, …])	Calculate expected value of a function with respect to the distribution by numerical integration.

continues on next page

Table 259 – continued from previous page

fit(data, *args, **kwds)	Return estimates of shape (if applicable), location, and scale parameters from data.
fit_loc_scale(data, *args)	Estimate loc and scale parameters from data using 1st and 2nd moments.
freeze(*args, **kwds)	Freeze the distribution for the given arguments.
interval(alpha, *args, **kwds)	Confidence interval with equal areas around the median.
isf(q, *args, **kwds)	Inverse survival function (inverse of *sf*) at q of the given RV.
logcdf(x, *args, **kwds)	Log of the cumulative distribution function at x of the given RV.
logpdf(x, *args, **kwds)	Log of the probability density function at x of the given RV.
logsf(x, *args, **kwds)	Log of the survival function of the given RV.
mean(*args, **kwds)	Mean of the distribution.
median(*args, **kwds)	Median of the distribution.
moment(n, *args, **kwds)	n-th order non-central moment of distribution.
nnlf(theta, x)	Negative loglikelihood function.
pdf(x, *args, **kwds)	Probability density function at x of the given RV.
ppf(q, *args, **kwds)	Percent point function (inverse of *cdf*) at q of the given RV.
rvs(*args, **kwds)	Random variates of given type.
sf(x, *args, **kwds)	Survival function (1 - *cdf*) at x of the given RV.
stats(*args, **kwds)	Some statistics of the given RV.
std(*args, **kwds)	Standard deviation of the distribution.
support(*args, **kwargs)	Support of the distribution.
var(*args, **kwds)	Variance of the distribution.

scipy.stats.rv_histogram.__call__

rv_histogram.**__call__**(**args*, ***kwds*)

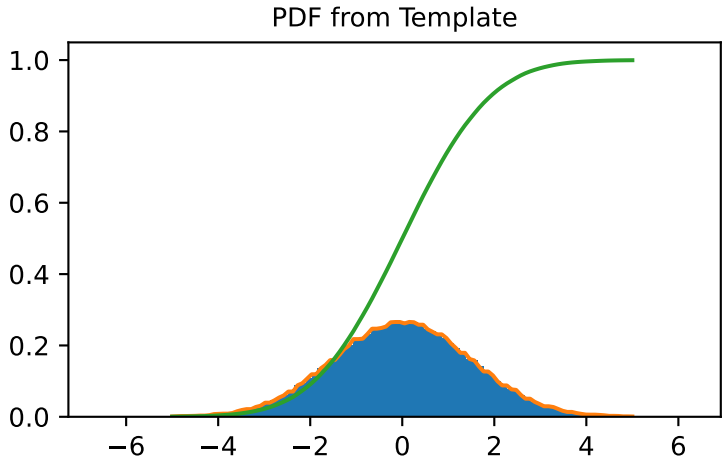
Freeze the distribution for the given arguments.

Parameters

arg1, arg2, arg3,…
: [array_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

Returns

rv_frozen [rv_frozen instance] The frozen distribution.



scipy.stats.rv_histogram.cdf

rv_histogram.**cdf**(*x*, **args*, ***kwds*)
Cumulative distribution function of the given RV.

Parameters

x [array_like] quantiles
arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

cdf [ndarray] Cumulative distribution function evaluated at *x*

scipy.stats.rv_histogram.entropy

rv_histogram.**entropy**(**args*, ***kwds*)
Differential entropy of the RV.

Parameters

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] Location parameter (default=0).
scale [array_like, optional (continuous distributions only).] Scale parameter (default=1).

Notes

Entropy is defined base *e*:

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

scipy.stats.rv_histogram.expect

rv_histogram.**expect**(*func=None*, *args=()*, *loc=0*, *scale=1*, *lb=None*, *ub=None*, *conditional=False*, ***kwds*)

Calculate expected value of a function with respect to the distribution by numerical integration.

The expected value of a function `f(x)` with respect to a distribution `dist` is defined as:

```
        ub
E[f(x)] = Integral(f(x) * dist.pdf(x)),
        lb
```

where `ub` and `lb` are arguments and `x` has the `dist.pdf(x)` distribution. If the bounds `lb` and `ub` correspond to the support of the distribution, e.g. `[-inf, inf]` in the default case, then the integral is the unrestricted expectation of `f(x)`. Also, the function `f(x)` may be defined such that `f(x)` is `0` outside a finite interval in which case the expectation is calculated within the finite range `[lb, ub]`.

Parameters

func [callable, optional] Function for which integral is calculated. Takes only one argument. The default is the identity mapping f(x) = x.

args [tuple, optional] Shape parameters of the distribution.

loc [float, optional] Location parameter (default=0).

scale [float, optional] Scale parameter (default=1).

lb, ub [scalar, optional] Lower and upper bound for integration. Default is set to the support of the distribution.

conditional [bool, optional] If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.

Additional keyword arguments are passed to the integration routine.

Returns

expect [float] The calculated expected value.

Notes

The integration behavior of this function is inherited from *scipy.integrate.quad*. Neither this function nor *scipy.integrate.quad* can verify whether the integral exists or is finite. For example `cauchy(0).mean()` returns `np.nan` and `cauchy(0).expect()` returns `0.0`.

The function is not vectorized.

Examples

To understand the effect of the bounds of integration consider

```
>>> from scipy.stats import expon
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0)
0.6321205588285578
```

This is close to

```
>>> expon(1).cdf(2.0) - expon(1).cdf(0.0)
0.6321205588285577
```

If `conditional=True`

```
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0, conditional=True)
1.0000000000000002
```

The slight deviation from 1 is due to numerical integration.

scipy.stats.rv_histogram.fit

`rv_histogram.`**`fit`**(*data*, **args*, ***kwds*)

Return estimates of shape (if applicable), location, and scale parameters from data. The default estimation method is Maximum Likelihood Estimation (MLE), but Method of Moments (MM) is also available.

Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, `self._fitstart(data)` is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments `f0`, `f1`, …, `fn` (for shape parameters) and `floc` and `fscale` (for location and scale parameters, respectively).

Parameters

data [array_like] Data to use in estimating the distribution parameters.

arg1, arg2, arg3,…
[floats, optional] Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to `_fitstart(data)`). No default value.

kwds [floats, optional]

- *loc*: initial guess of the distribution's location parameter.
- *scale*: initial guess of the distribution's scale parameter.

Special keyword arguments are recognized as holding certain parameters fixed:

- f0…fn : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fa` and `fix_a` are equivalent to `f0`, and `fb` and `fix_b` are equivalent to `f1`.
- floc : hold location parameter fixed to specified value.
- fscale : hold scale parameter fixed to specified value.
- optimizer : The optimizer to use. The optimizer must take `func`, and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.
- method : The method to use. The default is "MLE" (Maximum Likelihood Estimate); "MM" (Method of Moments) is also available.

Returns

parameter_tuple
: [tuple of floats] Estimates for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

Notes

With `method="MLE"` (default), the fit is computed by minimizing the negative log-likelihood function. A large, finite penalty (rather than infinite negative log-likelihood) is applied for observations beyond the support of the distribution.

With `method="MM"`, the fit is computed by minimizing the L2 norm of the relative errors between the first *k* raw (about zero) data moments and the corresponding distribution moments, where *k* is the number of non-fixed parameters. More precisely, the objective function is:

```
(((data_moments - dist_moments)
  / np.maximum(np.abs(data_moments), 1e-8))**2).sum()
```

where the constant `1e-8` avoids division by zero in case of vanishing data moments. Typically, this error norm can be reduced to zero. Note that the standard method of moments can produce parameters for which some data are outside the support of the fitted distribution; this implementation does nothing to prevent this.

For either method, the returned answer is not guaranteed to be globally optimal; it may only be locally optimal, or the optimization may fail altogether. If the data contain any of `np.nan`, `np.inf`, or `-np.inf`, the *fit* method will raise a `RuntimeError`.

Examples

Generate some data to fit: draw random variates from the *beta* distribution

```
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (`a`, `b`, `loc` and `scale`):

```
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let's keep `loc` and `scale` fixed:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using `f`-keywords. To keep the zero-th shape parameter `a` equal 1, use `f0=1` or, equivalently, `fa=1`:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. `norm` for example just returns estimates for location and scale:

```
>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```

scipy.stats.rv_histogram.fit_loc_scale

rv_histogram.**fit_loc_scale**(*data*, **args*)

Estimate loc and scale parameters from data using 1st and 2nd moments.

Parameters

data [array_like] Data to fit.

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

Returns

Lhat [float] Estimated location parameter for the data.

Shat [float] Estimated scale parameter for the data.

scipy.stats.rv_histogram.freeze

rv_histogram.**freeze**(**args*, ***kwds*)

Freeze the distribution for the given arguments.

Parameters

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

Returns

rv_frozen [rv_frozen instance] The frozen distribution.

scipy.stats.rv_histogram.interval

rv_histogram.**interval**(*alpha*, **args*, ***kwds*)

Confidence interval with equal areas around the median.

Parameters

alpha [array_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].

arg1, arg2, … [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] location parameter, Default is 0.

scale [array_like, optional] scale parameter, Default is 1.

Returns

a, b [ndarray of float] end-points of range that contain `100 * alpha %` of the rv's possible values.

scipy.stats.rv_histogram.isf

`rv_histogram.`**`isf`**(*q*, **args*, ***kwds*)

Inverse survival function (inverse of *sf*) at q of the given RV.

Parameters

q [array_like] upper tail probability

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

x [ndarray or scalar] Quantile corresponding to the upper tail probability q.

scipy.stats.rv_histogram.logcdf

`rv_histogram.`**`logcdf`**(*x*, **args*, ***kwds*)

Log of the cumulative distribution function at x of the given RV.

Parameters

x [array_like] quantiles

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

logcdf [array_like] Log of the cumulative distribution function evaluated at x

scipy.stats.rv_histogram.logpdf

`rv_histogram.`**`logpdf`**(*x*, **args*, ***kwds*)

Log of the probability density function at x of the given RV.

This uses a more numerically accurate calculation if available.

Parameters

x [array_like] quantiles

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

logpdf [array_like] Log of the probability density function evaluated at x

scipy.stats.rv_histogram.logsf

rv_histogram.**logsf**(*x*, **args*, ***kwds*)

Log of the survival function of the given RV.

Returns the log of the "survival function," defined as (1 - `cdf`), evaluated at *x*.

Parameters

x [array_like] quantiles

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

logsf [ndarray] Log of the survival function evaluated at *x*.

scipy.stats.rv_histogram.mean

rv_histogram.**mean**(**args*, ***kwds*)

Mean of the distribution.

Parameters

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

mean [float] the mean of the distribution

scipy.stats.rv_histogram.median

rv_histogram.**median**(**args*, ***kwds*)

Median of the distribution.

Parameters

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] Location parameter, Default is 0.

scale [array_like, optional] Scale parameter, Default is 1.

Returns

median [float] The median of the distribution.

See also:

`rv_discrete.ppf`

Inverse of the CDF

scipy.stats.rv_histogram.moment

`rv_histogram.`**`moment`**(*n*, **args*, ***kwds*)

n-th order non-central moment of distribution.

Parameters

n [int, n >= 1] Order of moment.

arg1, arg2, arg3,… [float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

scipy.stats.rv_histogram.nnlf

`rv_histogram.`**`nnlf`**(*theta*, *x*)

Negative loglikelihood function.

Notes

This is `-sum(log pdf(x, theta), axis=0)` where *theta* are the parameters (including loc and scale).

scipy.stats.rv_histogram.pdf

`rv_histogram.`**`pdf`**(*x*, **args*, ***kwds*)

Probability density function at x of the given RV.

Parameters

x [array_like] quantiles

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

pdf [ndarray] Probability density function evaluated at x

scipy.stats.rv_histogram.ppf

rv_histogram.**ppf**(*q*, **args*, ***kwds*)
Percent point function (inverse of *cdf*) at q of the given RV.

Parameters

q [array_like] lower tail probability
arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

x [array_like] quantile corresponding to the lower tail probability q.

scipy.stats.rv_histogram.rvs

rv_histogram.**rvs**(**args*, ***kwds*)
Random variates of given type.

Parameters

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] Location parameter (default=0).
scale [array_like, optional] Scale parameter (default=1).
size [int or tuple of ints, optional] Defining number of random variates (default is 1).
random_state [{None, int, `numpy.random.Generator`,] `numpy.random.RandomState`}, optional
If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Returns

rvs [ndarray or scalar] Random variates of given *size*.

scipy.stats.rv_histogram.sf

rv_histogram.**sf**(*x*, **args*, ***kwds*)
Survival function (1 - *cdf*) at x of the given RV.

Parameters

x [array_like] quantiles
arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

sf [array_like] Survival function evaluated at x

scipy.stats.rv_histogram.stats

rv_histogram.**stats**(**args*, ***kwds*)

Some statistics of the given RV.

Parameters

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional (continuous RVs only)] scale parameter (default=1)

moments [str, optional] composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

Returns

stats [sequence] of requested moments.

scipy.stats.rv_histogram.std

rv_histogram.**std**(**args*, ***kwds*)

Standard deviation of the distribution.

Parameters

arg1, arg2, arg3,… [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

std [float] standard deviation of the distribution

scipy.stats.rv_histogram.support

rv_histogram.**support**(**args*, ***kwargs*)

Support of the distribution.

Parameters

arg1, arg2, … [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] location parameter, Default is 0.

scale [array_like, optional] scale parameter, Default is 1.

Returns

a, b [array_like] end-points of the distribution's support.

scipy.stats.rv_histogram.var

rv_histogram.**var**(**args*, ***kwds*)
Variance of the distribution.

Parameters

arg1, arg2, arg3,…
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

var [float] the variance of the distribution

Continuous distributions

alpha	An alpha continuous random variable.
anglit	An anglit continuous random variable.
arcsine	An arcsine continuous random variable.
argus	Argus distribution
beta	A beta continuous random variable.
betaprime	A beta prime continuous random variable.
bradford	A Bradford continuous random variable.
burr	A Burr (Type III) continuous random variable.
burr12	A Burr (Type XII) continuous random variable.
cauchy	A Cauchy continuous random variable.
chi	A chi continuous random variable.
chi2	A chi-squared continuous random variable.
cosine	A cosine continuous random variable.
crystalball	Crystalball distribution
dgamma	A double gamma continuous random variable.
dweibull	A double Weibull continuous random variable.
erlang	An Erlang continuous random variable.
expon	An exponential continuous random variable.
exponnorm	An exponentially modified Normal continuous random variable.
exponweib	An exponentiated Weibull continuous random variable.
exponpow	An exponential power continuous random variable.
f	An F continuous random variable.
fatiguelife	A fatigue-life (Birnbaum-Saunders) continuous random variable.
fisk	A Fisk continuous random variable.
foldcauchy	A folded Cauchy continuous random variable.
foldnorm	A folded normal continuous random variable.
genlogistic	A generalized logistic continuous random variable.
gennorm	A generalized normal continuous random variable.
genpareto	A generalized Pareto continuous random variable.
genexpon	A generalized exponential continuous random variable.
genextreme	A generalized extreme value continuous random variable.
gausshyper	A Gauss hypergeometric continuous random variable.

continues on next page

Table 260 – continued from previous page

gamma	A gamma continuous random variable.
gengamma	A generalized gamma continuous random variable.
genhalflogistic	A generalized half-logistic continuous random variable.
genhyperbolic	A generalized hyperbolic continuous random variable.
geninvgauss	A Generalized Inverse Gaussian continuous random variable.
gilbrat	A Gilbrat continuous random variable.
gompertz	A Gompertz (or truncated Gumbel) continuous random variable.
gumbel_r	A right-skewed Gumbel continuous random variable.
gumbel_l	A left-skewed Gumbel continuous random variable.
halfcauchy	A Half-Cauchy continuous random variable.
halflogistic	A half-logistic continuous random variable.
halfnorm	A half-normal continuous random variable.
halfgennorm	The upper half of a generalized normal continuous random variable.
hypsecant	A hyperbolic secant continuous random variable.
invgamma	An inverted gamma continuous random variable.
invgauss	An inverse Gaussian continuous random variable.
invweibull	An inverted Weibull continuous random variable.
johnsonsb	A Johnson SB continuous random variable.
johnsonsu	A Johnson SU continuous random variable.
kappa4	Kappa 4 parameter distribution.
kappa3	Kappa 3 parameter distribution.
ksone	Kolmogorov-Smirnov one-sided test statistic distribution.
kstwo	Kolmogorov-Smirnov two-sided test statistic distribution.
kstwobign	Limiting distribution of scaled Kolmogorov-Smirnov two-sided test statistic.
laplace	A Laplace continuous random variable.
laplace_asymmetric	An asymmetric Laplace continuous random variable.
levy	A Levy continuous random variable.
levy_l	A left-skewed Levy continuous random variable.
levy_stable	A Levy-stable continuous random variable.
logistic	A logistic (or Sech-squared) continuous random variable.
loggamma	A log gamma continuous random variable.
loglaplace	A log-Laplace continuous random variable.
lognorm	A lognormal continuous random variable.
loguniform	A loguniform or reciprocal continuous random variable.
lomax	A Lomax (Pareto of the second kind) continuous random variable.
maxwell	A Maxwell continuous random variable.
mielke	A Mielke Beta-Kappa / Dagum continuous random variable.
moyal	A Moyal continuous random variable.
nakagami	A Nakagami continuous random variable.
ncx2	A non-central chi-squared continuous random variable.
ncf	A non-central F distribution continuous random variable.
nct	A non-central Student's t continuous random variable.
norm	A normal continuous random variable.
norminvgauss	A Normal Inverse Gaussian continuous random variable.

continues on next page

Table 260 – continued from previous page

pareto	A Pareto continuous random variable.
pearson3	A pearson type III continuous random variable.
powerlaw	A power-function continuous random variable.
powerlognorm	A power log-normal continuous random variable.
powernorm	A power normal continuous random variable.
rdist	An R-distributed (symmetric beta) continuous random variable.
rayleigh	A Rayleigh continuous random variable.
rice	A Rice continuous random variable.
recipinvgauss	A reciprocal inverse Gaussian continuous random variable.
semicircular	A semicircular continuous random variable.
skewcauchy	A skewed Cauchy random variable.
skewnorm	A skew-normal random variable.
studentized_range	A studentized range continuous random variable.
t	A Student's t continuous random variable.
trapezoid	A trapezoidal continuous random variable.
triang	A triangular continuous random variable.
truncexpon	A truncated exponential continuous random variable.
truncnorm	A truncated normal continuous random variable.
tukeylambda	A Tukey-Lamdba continuous random variable.
uniform	A uniform continuous random variable.
vonmises	A Von Mises continuous random variable.
vonmises_line	A Von Mises continuous random variable.
wald	A Wald continuous random variable.
weibull_min	Weibull minimum continuous random variable.
weibull_max	Weibull maximum continuous random variable.
wrapcauchy	A wrapped Cauchy continuous random variable.

scipy.stats.alpha

scipy.stats.**alpha = <scipy.stats._continuous_distns.alpha_gen object>**

An alpha continuous random variable.

As an instance of the *rv_continuous* class, *alpha* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *alpha* ([1], [2]) is:

$$f(x, a) = \frac{1}{x^2 \Phi(a) \sqrt{2\pi}} * \exp(-\frac{1}{2}(a - 1/x)^2)$$

where Φ is the normal CDF, $x > 0$, and $a > 0$.

alpha takes `a` as a shape parameter.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `alpha.pdf(x, a, loc, scale)` is identically equivalent to `alpha.pdf(y, a) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1], [2]

Examples

```
>>> from scipy.stats import alpha
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 3.57
>>> mean, var, skew, kurt = alpha.stats(a, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(alpha.ppf(0.01, a),
...                 alpha.ppf(0.99, a), 100)
>>> ax.plot(x, alpha.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='alpha pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = alpha(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

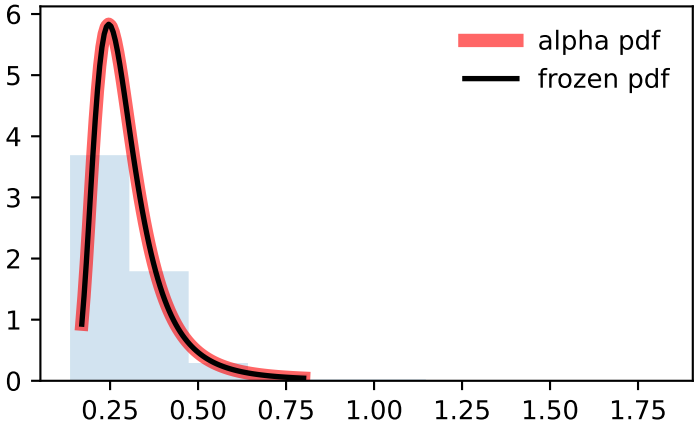
```
>>> vals = alpha.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], alpha.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = alpha.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(a, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, a, loc=0, scale=1)	Probability density function.
logpdf(x, a, loc=0, scale=1)	Log of the probability density function.
cdf(x, a, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, a, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, a, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, a, loc=0, scale=1)	Log of the survival function.
ppf(q, a, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, a, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, a, loc=0, scale=1)	Non-central moment of order n
stats(a, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(a, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(a, loc=0, scale=1)	Median of the distribution.
mean(a, loc=0, scale=1)	Mean of the distribution.
var(a, loc=0, scale=1)	Variance of the distribution.
std(a, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, a, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.anglit

scipy.stats.**anglit = <scipy.stats._continuous_distns.anglit_gen object>**

An anglit continuous random variable.

As an instance of the *rv_continuous* class, *anglit* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *anglit* is:

$$f(x) = \sin(2x + \pi/2) = \cos(2x)$$

for $-\pi/4 \leq x \leq \pi/4$.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `anglit.pdf(x, loc, scale)` is identically equivalent to `anglit.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import anglit
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = anglit.stats(moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(anglit.ppf(0.01),
...                 anglit.ppf(0.99), 100)
>>> ax.plot(x, anglit.pdf(x),
...         'r-', lw=5, alpha=0.6, label='anglit pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = anglit()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

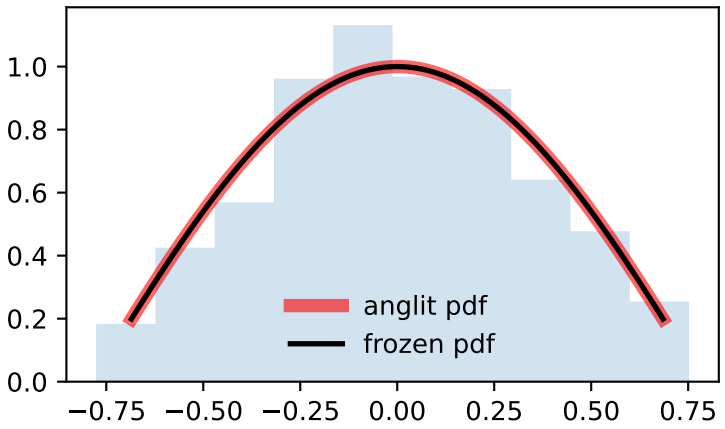
```
>>> vals = anglit.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], anglit.cdf(vals))
True
```

Generate random numbers:

```
>>> r = anglit.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, loc=0, scale=1)	Probability density function.
logpdf(x, loc=0, scale=1)	Log of the probability density function.
cdf(x, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, loc=0, scale=1)	Log of the survival function.
ppf(q, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, loc=0, scale=1)	Non-central moment of order n
stats(loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(loc=0, scale=1)	Median of the distribution.
mean(loc=0, scale=1)	Mean of the distribution.
var(loc=0, scale=1)	Variance of the distribution.
std(loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.arcsine

scipy.stats.**arcsine = <scipy.stats._continuous_distns.arcsine_gen object>**

An arcsine continuous random variable.

As an instance of the *rv_continuous* class, *arcsine* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *arcsine* is:

$$f(x) = \frac{1}{\pi\sqrt{x(1-x)}}$$

for $0 < x < 1$.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `arcsine.pdf(x, loc, scale)` is identically equivalent to `arcsine.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import arcsine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = arcsine.stats(moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(arcsine.ppf(0.01),
...                 arcsine.ppf(0.99), 100)
>>> ax.plot(x, arcsine.pdf(x),
...         'r-', lw=5, alpha=0.6, label='arcsine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = arcsine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

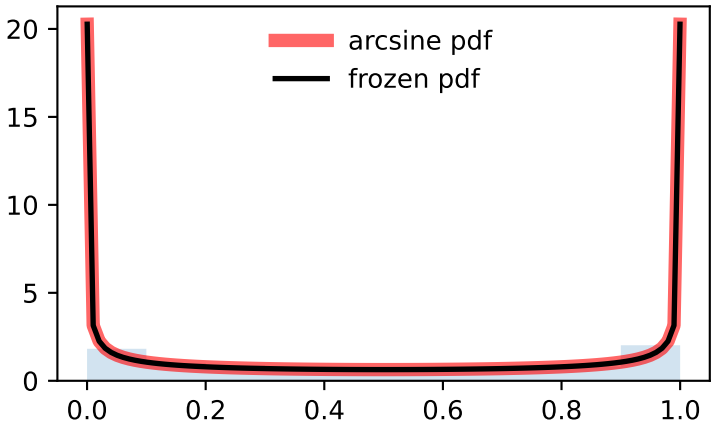
```
>>> vals = arcsine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], arcsine.cdf(vals))
True
```

Generate random numbers:

```
>>> r = arcsine.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, loc=0, scale=1)	Probability density function.
logpdf(x, loc=0, scale=1)	Log of the probability density function.
cdf(x, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, loc=0, scale=1)	Log of the survival function.
ppf(q, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, loc=0, scale=1)	Non-central moment of order n
stats(loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(loc=0, scale=1)	Median of the distribution.
mean(loc=0, scale=1)	Mean of the distribution.
var(loc=0, scale=1)	Variance of the distribution.
std(loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.argus

scipy.stats.**argus = <scipy.stats._continuous_distns.argus_gen object>**

Argus distribution

As an instance of the *rv_continuous* class, *argus* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *argus* is:

$$f(x, \chi) = \frac{\chi^3}{\sqrt{2\pi}\Psi(\chi)} x\sqrt{1-x^2}\exp(-\chi^2(1-x^2)/2)$$

for $0 < x < 1$ and $\chi > 0$, where

$$\Psi(\chi) = \Phi(\chi) - \chi\phi(\chi) - 1/2$$

with Φ and ϕ being the CDF and PDF of a standard normal distribution, respectively.

argus takes χ as shape a parameter.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `argus.pdf(x, chi, loc, scale)` is identically equivalent to `argus.pdf(y, chi) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

New in version 0.19.0.

References

[1]

Examples

```
>>> from scipy.stats import argus
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> chi = 1
>>> mean, var, skew, kurt = argus.stats(chi, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(argus.ppf(0.01, chi),
...                 argus.ppf(0.99, chi), 100)
>>> ax.plot(x, argus.pdf(x, chi),
...         'r-', lw=5, alpha=0.6, label='argus pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = argus(chi)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

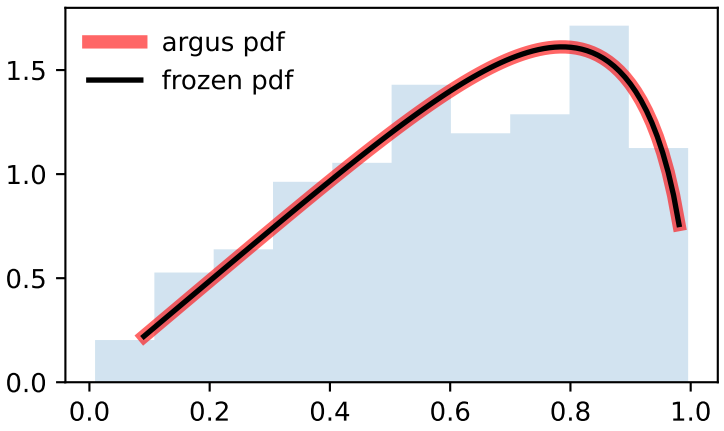
```
>>> vals = argus.ppf([0.001, 0.5, 0.999], chi)
>>> np.allclose([0.001, 0.5, 0.999], argus.cdf(vals, chi))
True
```

Generate random numbers:

```
>>> r = argus.rvs(chi, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(chi, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, chi, loc=0, scale=1)	Probability density function.
logpdf(x, chi, loc=0, scale=1)	Log of the probability density function.
cdf(x, chi, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, chi, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, chi, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, chi, loc=0, scale=1)	Log of the survival function.
ppf(q, chi, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).

expect(func, args=(chi,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(chi, loc=0, scale=1)	Median of the distribution.
mean(chi, loc=0, scale=1)	Mean of the distribution.
var(chi, loc=0, scale=1)	Variance of the distribution.
std(chi, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, chi, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.beta

scipy.stats.**beta = <scipy.stats._continuous_distns.beta_gen object>**

A beta continuous random variable.

As an instance of the *rv_continuous* class, *beta* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *beta* is:

$$f(x, a, b) = \frac{\Gamma(a+b) x^{a-1} (1-x)^{b-1}}{\Gamma(a) \Gamma(b)}$$

for $0 <= x <= 1$, $a > 0$, $b > 0$, where Γ is the gamma function (*scipy.special.gamma*).

beta takes a and b as shape parameters.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `beta.pdf(x, a, b, loc, scale)` is identically equivalent to `beta.pdf(y, a, b) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import beta
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 2.31, 0.627
>>> mean, var, skew, kurt = beta.stats(a, b, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(beta.ppf(0.01, a, b),
...                 beta.ppf(0.99, a, b), 100)
>>> ax.plot(x, beta.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='beta pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = beta(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

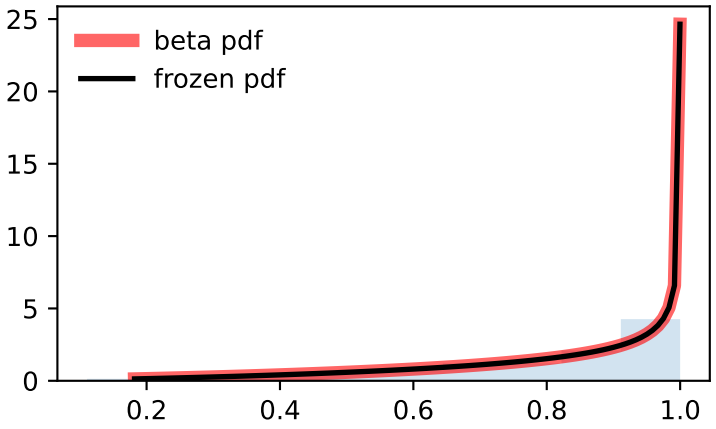
```
>>> vals = beta.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], beta.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = beta.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(a, b, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, a, b, loc=0, scale=1)	Probability density function.
logpdf(x, a, b, loc=0, scale=1)	Log of the probability density function.
cdf(x, a, b, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, a, b, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, a, b, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, a, b, loc=0, scale=1)	Log of the survival function.
ppf(q, a, b, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, a, b, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, a, b, loc=0, scale=1)	Non-central moment of order n
stats(a, b, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(a, b, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(a, b, loc=0, scale=1)	Median of the distribution.
mean(a, b, loc=0, scale=1)	Mean of the distribution.
var(a, b, loc=0, scale=1)	Variance of the distribution.
std(a, b, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, a, b, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.betaprime

scipy.stats.**betaprime = <scipy.stats._continuous_distns.betaprime_gen object>**

A beta prime continuous random variable.

As an instance of the *rv_continuous* class, *betaprime* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *betaprime* is:

$$f(x, a, b) = \frac{x^{a-1}(1+x)^{-a-b}}{\beta(a, b)}$$

for $x >= 0$, $a > 0$, $b > 0$, where $\beta(a, b)$ is the beta function (see *scipy.special.beta*).

betaprime takes `a` and `b` as shape parameters.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `betaprime.pdf(x, a, b, loc, scale)` is identically equivalent to `betaprime.pdf(y, a, b) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import betaprime
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 5, 6
>>> mean, var, skew, kurt = betaprime.stats(a, b, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(betaprime.ppf(0.01, a, b),
...                 betaprime.ppf(0.99, a, b), 100)
>>> ax.plot(x, betaprime.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='betaprime pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = betaprime(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

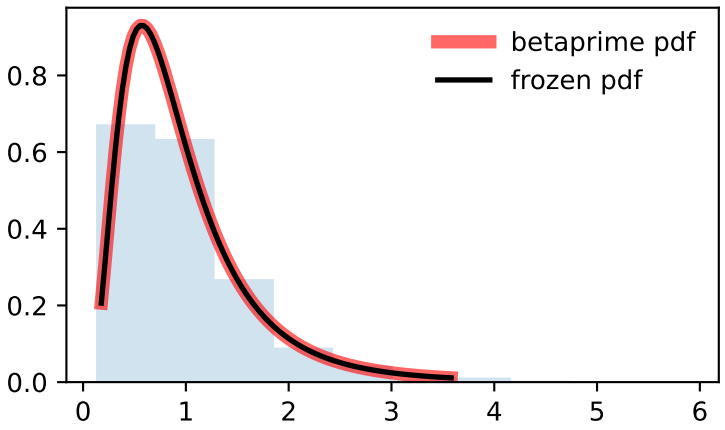
```
>>> vals = betaprime.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], betaprime.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = betaprime.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(a, b, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, a, b, loc=0, scale=1)	Probability density function.
logpdf(x, a, b, loc=0, scale=1)	Log of the probability density function.
cdf(x, a, b, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, a, b, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, a, b, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, a, b, loc=0, scale=1)	Log of the survival function.
ppf(q, a, b, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, a, b, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, a, b, loc=0, scale=1)	Non-central moment of order n
stats(a, b, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(a, b, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(a, b, loc=0, scale=1)	Median of the distribution.
mean(a, b, loc=0, scale=1)	Mean of the distribution.
var(a, b, loc=0, scale=1)	Variance of the distribution.
std(a, b, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, a, b, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.bradford

scipy.stats.**bradford = <scipy.stats._continuous_distns.bradford_gen object>**

A Bradford continuous random variable.

As an instance of the *rv_continuous* class, *bradford* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *bradford* is:

$$f(x, c) = \frac{c}{\log(1+c)(1+cx)}$$

for $0 <= x <= 1$ and $c > 0$.

bradford takes `c` as a shape parameter for c.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `bradford.pdf(x, c, loc, scale)` is identically equivalent to `bradford.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import bradford
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.299
>>> mean, var, skew, kurt = bradford.stats(c, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(bradford.ppf(0.01, c),
...                 bradford.ppf(0.99, c), 100)
>>> ax.plot(x, bradford.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='bradford pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = bradford(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

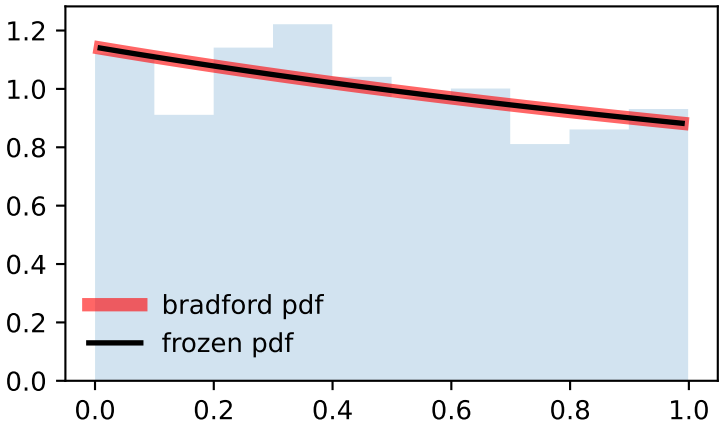
```
>>> vals = bradford.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], bradford.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = bradford.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, loc=0, scale=1)	Probability density function.
logpdf(x, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, c, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, c, loc=0, scale=1)	Log of the survival function.
ppf(q, c, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, c, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, c, loc=0, scale=1)	Non-central moment of order n
stats(c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(c, loc=0, scale=1)	Median of the distribution.
mean(c, loc=0, scale=1)	Mean of the distribution.
var(c, loc=0, scale=1)	Variance of the distribution.
std(c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.burr

scipy.stats.**burr = <scipy.stats._continuous_distns.burr_gen object>**

A Burr (Type III) continuous random variable.

As an instance of the *rv_continuous* class, *burr* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

fisk

a special case of either *burr* or *burr12* with d=1

burr12

Burr Type XII distribution

mielke

Mielke Beta-Kappa / Dagum distribution

Notes

The probability density function for *burr* is:

$$f(x, c, d) = cdx^{-c-1}/(1 + x^{-c})^{d+1}$$

for $x >= 0$ and $c, d > 0$.

burr takes c and d as shape parameters.

This is the PDF corresponding to the third CDF given in Burr's list; specifically, it is equation (11) in Burr's paper [1]. The distribution is also commonly referred to as the Dagum distribution [2]. If the parameter $c < 1$ then the mean of the distribution does not exist and if $c < 2$ the variance does not exist [2]. The PDF is finite at the left endpoint $x = 0$ if $c * d >= 1$.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `burr.pdf(x, c, d, loc, scale)` is identically equivalent to `burr.pdf(y, c, d) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1], [2], [3]

Examples

```
>>> from scipy.stats import burr
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c, d = 10.5, 4.3
>>> mean, var, skew, kurt = burr.stats(c, d, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(burr.ppf(0.01, c, d),
...                 burr.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr.pdf(x, c, d),
...         'r-', lw=5, alpha=0.6, label='burr pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = burr(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

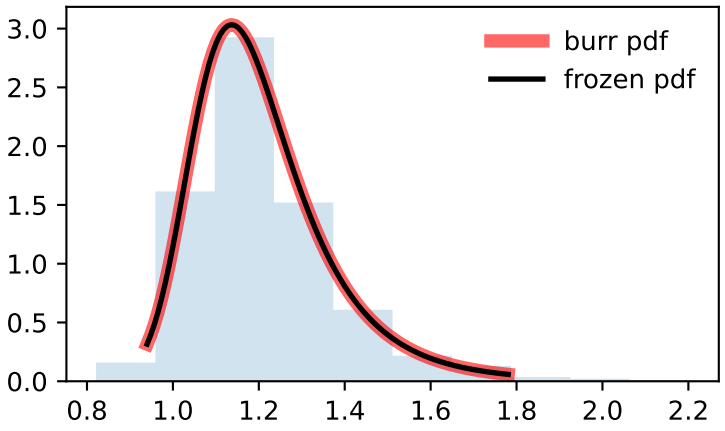
```
>>> vals = burr.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = burr.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(c, d, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, d, loc=0, scale=1)	Probability density function.
logpdf(x, c, d, loc=0, scale=1)	Log of the probability density function.
cdf(x, c, d, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, c, d, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, c, d, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, c, d, loc=0, scale=1)	Log of the survival function.
ppf(q, c, d, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, c, d, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, c, d, loc=0, scale=1)	Non-central moment of order n
stats(c, d, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, d, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(c, d), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(c, d, loc=0, scale=1)	Median of the distribution.
mean(c, d, loc=0, scale=1)	Mean of the distribution.
var(c, d, loc=0, scale=1)	Variance of the distribution.
std(c, d, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, d, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.burr12

scipy.stats.**burr12 = <scipy.stats._continuous_distns.burr12_gen object>**

A Burr (Type XII) continuous random variable.

As an instance of the *rv_continuous* class, *burr12* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

fisk

a special case of either *burr* or *burr12* with `d=1`

burr

Burr Type III distribution

Notes

The probability density function for *burr* is:

$$f(x, c, d) = cdx^{c-1}/(1 + x^c)^{d+1}$$

for $x >= 0$ and $c, d > 0$.

burr12 takes `c` and `d` as shape parameters for c and d.

This is the PDF corresponding to the twelfth CDF given in Burr's list; specifically, it is equation (20) in Burr's paper [1].

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `burr12.pdf(x, c, d, loc, scale)` is identically equivalent to `burr12.pdf(y, c, d) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

The Burr type 12 distribution is also sometimes referred to as the Singh-Maddala distribution from NIST [2].

References

[1], [2], [3]

Examples

```
>>> from scipy.stats import burr12
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c, d = 10, 4
>>> mean, var, skew, kurt = burr12.stats(c, d, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(burr12.ppf(0.01, c, d),
...                 burr12.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr12.pdf(x, c, d),
...         'r-', lw=5, alpha=0.6, label='burr12 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = burr12(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

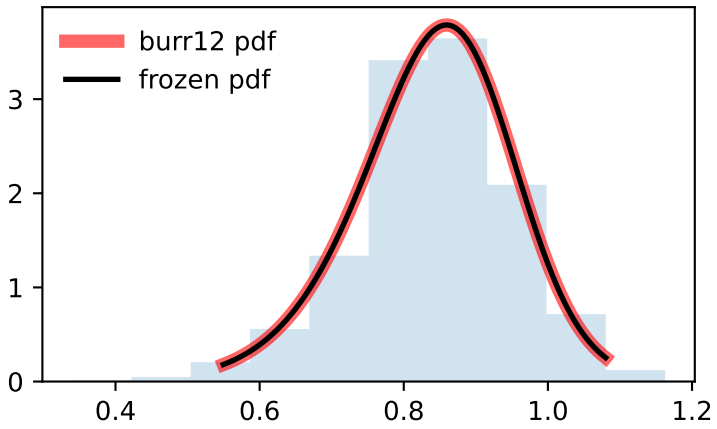
```
>>> vals = burr12.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr12.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = burr12.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(c, d, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, d, loc=0, scale=1)	Probability density function.
logpdf(x, c, d, loc=0, scale=1)	Log of the probability density function.
cdf(x, c, d, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, c, d, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, c, d, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, c, d, loc=0, scale=1)	Log of the survival function.
ppf(q, c, d, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, c, d, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, c, d, loc=0, scale=1)	Non-central moment of order n
stats(c, d, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, d, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(c, d), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(c, d, loc=0, scale=1)	Median of the distribution.
mean(c, d, loc=0, scale=1)	Mean of the distribution.
var(c, d, loc=0, scale=1)	Variance of the distribution.
std(c, d, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, d, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.cauchy

scipy.stats.**cauchy = <scipy.stats._continuous_distns.cauchy_gen object>**

A Cauchy continuous random variable.

As an instance of the *rv_continuous* class, *cauchy* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *cauchy* is

$$f(x) = \frac{1}{\pi(1+x^2)}$$

for a real number x.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `cauchy.pdf(x, loc, scale)` is identically equivalent to `cauchy.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import cauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = cauchy.stats(moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(cauchy.ppf(0.01),
...                 cauchy.ppf(0.99), 100)
>>> ax.plot(x, cauchy.pdf(x),
...         'r-', lw=5, alpha=0.6, label='cauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = cauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

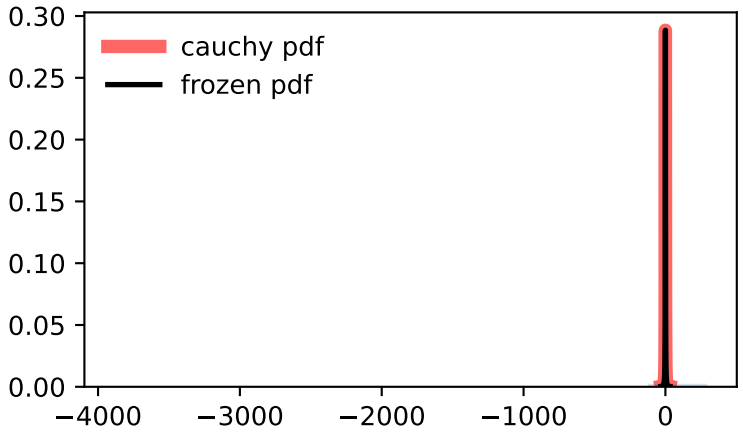
```
>>> vals = cauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cauchy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = cauchy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, loc=0, scale=1)	Probability density function.
logpdf(x, loc=0, scale=1)	Log of the probability density function.
cdf(x, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, loc=0, scale=1)	Log of the survival function.
ppf(q, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, loc=0, scale=1)	Non-central moment of order n
stats(loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(loc=0, scale=1)	Median of the distribution.
mean(loc=0, scale=1)	Mean of the distribution.
var(loc=0, scale=1)	Variance of the distribution.
std(loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.chi

scipy.stats.**chi = <scipy.stats._continuous_distns.chi_gen object>**

A chi continuous random variable.

As an instance of the *rv_continuous* class, *chi* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *chi* is:

$$f(x, k) = \frac{1}{2^{k/2-1}\Gamma\left(k/2\right)} x^{k-1} \exp\left(-x^2/2\right)$$

for $x >= 0$ and $k > 0$ (degrees of freedom, denoted `df` in the implementation). Γ is the gamma function (*scipy.special.gamma*).

Special cases of *chi* are:

- `chi(1, loc, scale)` is equivalent to *halfnorm*
- `chi(2, 0, scale)` is equivalent to *rayleigh*
- `chi(3, 0, scale)` is equivalent to *maxwell*

chi takes `df` as a shape parameter.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi.pdf(x, df, loc, scale)` is identically equivalent to `chi.pdf(y, df) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import chi
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> df = 78
>>> mean, var, skew, kurt = chi.stats(df, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(chi.ppf(0.01, df),
...                 chi.ppf(0.99, df), 100)
>>> ax.plot(x, chi.pdf(x, df),
...         'r-', lw=5, alpha=0.6, label='chi pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = chi(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

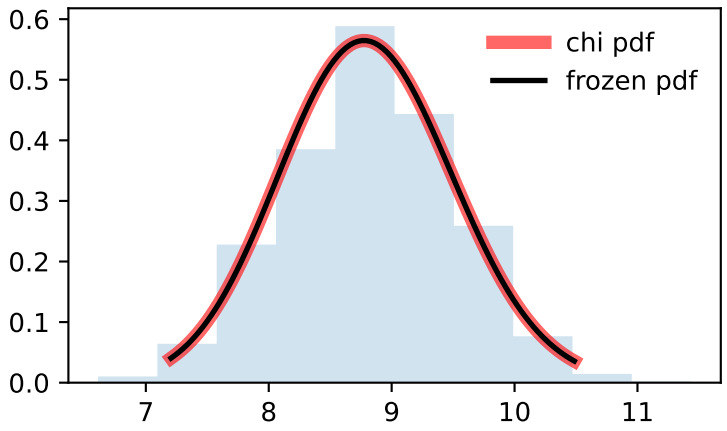
```
>>> vals = chi.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = chi.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(df, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, df, loc=0, scale=1)	Probability density function.
logpdf(x, df, loc=0, scale=1)	Log of the probability density function.
cdf(x, df, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, df, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, df, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, df, loc=0, scale=1)	Log of the survival function.
ppf(q, df, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, df, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, df, loc=0, scale=1)	Non-central moment of order n
stats(df, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(df, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(df,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(df, loc=0, scale=1)	Median of the distribution.
mean(df, loc=0, scale=1)	Mean of the distribution.
var(df, loc=0, scale=1)	Variance of the distribution.
std(df, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, df, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.chi2

scipy.stats.**chi2 = <scipy.stats._continuous_distns.chi2_gen object>**

A chi-squared continuous random variable.

For the noncentral chi-square distribution, see *ncx2*.

As an instance of the *rv_continuous* class, *chi2* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

ncx2

Notes

The probability density function for *chi2* is:

$$f(x, k) = \frac{1}{2^{k/2}\Gamma\left(k/2\right)} x^{k/2-1} \exp\left(-x/2\right)$$

for $x > 0$ and $k > 0$ (degrees of freedom, denoted `df` in the implementation).

chi2 takes `df` as a shape parameter.

The chi-squared distribution is a special case of the gamma distribution, with gamma parameters `a = df/2`, `loc = 0` and `scale = 2`.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi2.pdf(x, df, loc, scale)` is identically equivalent to `chi2.pdf(y, df) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import chi2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> df = 55
>>> mean, var, skew, kurt = chi2.stats(df, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(chi2.ppf(0.01, df),
...                 chi2.ppf(0.99, df), 100)
>>> ax.plot(x, chi2.pdf(x, df),
...         'r-', lw=5, alpha=0.6, label='chi2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = chi2(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

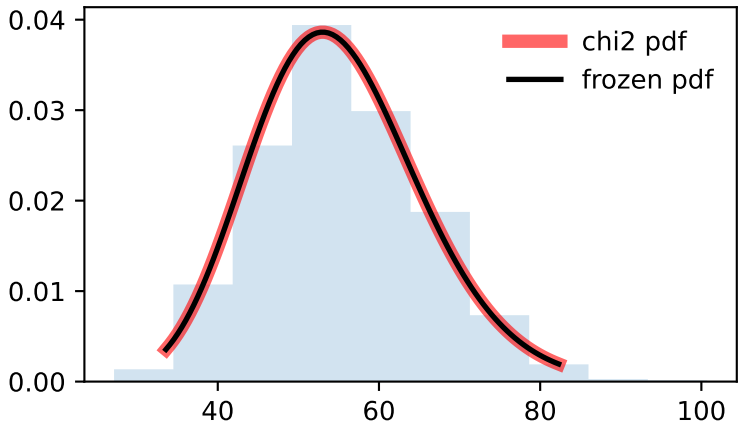
```
>>> vals = chi2.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi2.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = chi2.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(df, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, df, loc=0, scale=1)	Probability density function.
logpdf(x, df, loc=0, scale=1)	Log of the probability density function.
cdf(x, df, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, df, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, df, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, df, loc=0, scale=1)	Log of the survival function.
ppf(q, df, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, df, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, df, loc=0, scale=1)	Non-central moment of order n
stats(df, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(df, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(df,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(df, loc=0, scale=1)	Median of the distribution.
mean(df, loc=0, scale=1)	Mean of the distribution.
var(df, loc=0, scale=1)	Variance of the distribution.
std(df, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, df, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.cosine

scipy.stats.**cosine = <scipy.stats._continuous_distns.cosine_gen object>**

A cosine continuous random variable.

As an instance of the *rv_continuous* class, *cosine* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The cosine distribution is an approximation to the normal distribution. The probability density function for *cosine* is:

$$f(x) = \frac{1}{2\pi}(1+\cos(x))$$

for $-\pi \leq x \leq \pi$.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `cosine.pdf(x, loc, scale)` is identically equivalent to `cosine.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import cosine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = cosine.stats(moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(cosine.ppf(0.01),
...                 cosine.ppf(0.99), 100)
>>> ax.plot(x, cosine.pdf(x),
...         'r-', lw=5, alpha=0.6, label='cosine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = cosine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

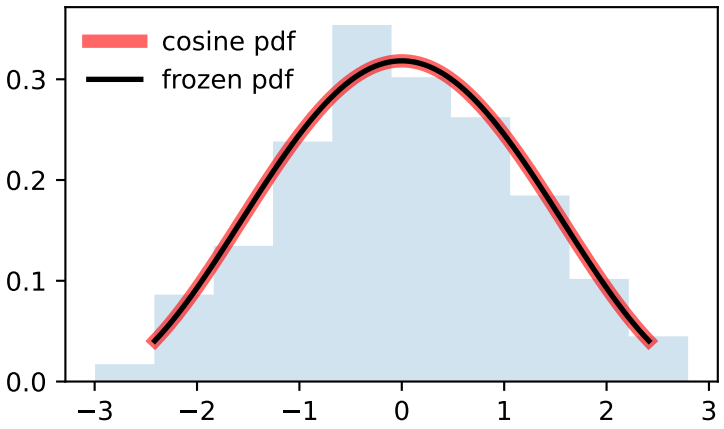
```
>>> vals = cosine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cosine.cdf(vals))
True
```

Generate random numbers:

```
>>> r = cosine.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, loc=0, scale=1)	Probability density function.
logpdf(x, loc=0, scale=1)	Log of the probability density function.
cdf(x, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, loc=0, scale=1)	Log of the survival function.
ppf(q, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, loc=0, scale=1)	Non-central moment of order n
stats(loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(loc=0, scale=1)	Median of the distribution.
mean(loc=0, scale=1)	Mean of the distribution.
var(loc=0, scale=1)	Variance of the distribution.
std(loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.crystalball

scipy.stats.**crystalball = <scipy.stats._continuous_distns.crystalball_gen object>**

Crystalball distribution

As an instance of the *rv_continuous* class, *crystalball* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *crystalball* is:

$$f(x, \beta, m) = \begin{cases} N \exp(-x^2/2), & \text{for } x > -\beta \\ N A (B - x)^{-m} & \text{for } x \leq -\beta \end{cases}$$

where $A = (m/|\beta|)^m \exp(-\beta^2/2)$, $B = m/|\beta| - |\beta|$ and N is a normalisation constant.

crystalball takes $\beta > 0$ and $m > 1$ as shape parameters. β defines the point where the pdf changes from a power-law to a Gaussian distribution. m is the power of the power-law tail.

References

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `crystalball.pdf(x, beta, m, loc, scale)` is identically equivalent to `crystalball.pdf(y, beta, m) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

New in version 0.19.0.

[1]

Examples

```
>>> from scipy.stats import crystalball
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> beta, m = 2, 3
>>> mean, var, skew, kurt = crystalball.stats(beta, m, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(crystalball.ppf(0.01, beta, m),
...                 crystalball.ppf(0.99, beta, m), 100)
>>> ax.plot(x, crystalball.pdf(x, beta, m),
...         'r-', lw=5, alpha=0.6, label='crystalball pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = crystalball(beta, m)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

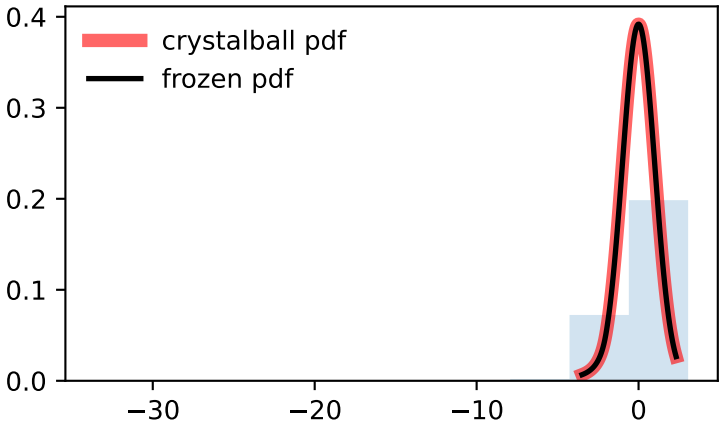
```
>>> vals = crystalball.ppf([0.001, 0.5, 0.999], beta, m)
>>> np.allclose([0.001, 0.5, 0.999], crystalball.cdf(vals, beta, m))
True
```

Generate random numbers:

```
>>> r = crystalball.rvs(beta, m, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(beta, m, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, beta, m, loc=0, scale=1)	Probability density function.
logpdf(x, beta, m, loc=0, scale=1)	Log of the probability density function.
cdf(x, beta, m, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, beta, m, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, beta, m, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, beta, m, loc=0, scale=1)	Log of the survival function.
ppf(q, beta, m, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, beta, m, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, beta, m, loc=0, scale=1)	Non-central moment of order n
stats(beta, m, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(beta, m, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(beta, m), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(beta, m, loc=0, scale=1)	Median of the distribution.
mean(beta, m, loc=0, scale=1)	Mean of the distribution.
var(beta, m, loc=0, scale=1)	Variance of the distribution.
std(beta, m, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, beta, m, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.dgamma

scipy.stats.**dgamma = <scipy.stats._continuous_distns.dgamma_gen object>**

A double gamma continuous random variable.

As an instance of the *rv_continuous* class, *dgamma* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *dgamma* is:

$$f(x, a) = \frac{1}{2\Gamma(a)}|x|^{a-1}\exp(-|x|)$$

for a real number x and $a > 0$. Γ is the gamma function (*scipy.special.gamma*).

dgamma takes `a` as a shape parameter for a.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `dgamma.pdf(x, a, loc, scale)` is identically equivalent to `dgamma.pdf(y, a) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import dgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 1.1
>>> mean, var, skew, kurt = dgamma.stats(a, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(dgamma.ppf(0.01, a),
...                 dgamma.ppf(0.99, a), 100)
>>> ax.plot(x, dgamma.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='dgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = dgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

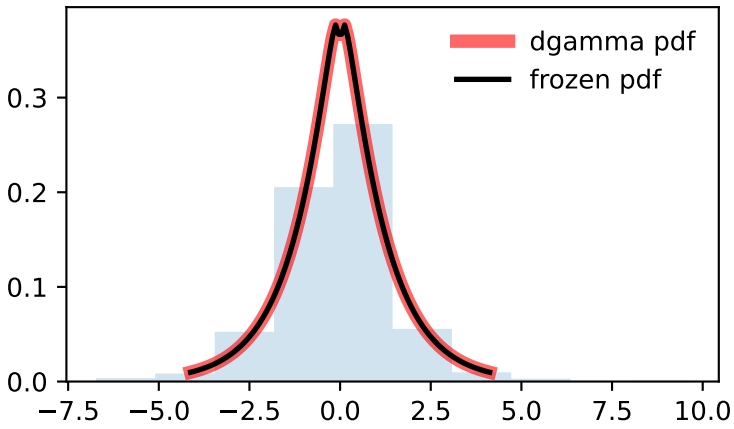
```
>>> vals = dgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], dgamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = dgamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(a, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, a, loc=0, scale=1)	Probability density function.
logpdf(x, a, loc=0, scale=1)	Log of the probability density function.
cdf(x, a, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, a, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, a, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, a, loc=0, scale=1)	Log of the survival function.
ppf(q, a, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, a, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, a, loc=0, scale=1)	Non-central moment of order n
stats(a, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(a, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(a, loc=0, scale=1)	Median of the distribution.
mean(a, loc=0, scale=1)	Mean of the distribution.
var(a, loc=0, scale=1)	Variance of the distribution.
std(a, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, a, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.dweibull

scipy.stats.**dweibull = <scipy.stats._continuous_distns.dweibull_gen object>**

A double Weibull continuous random variable.

As an instance of the *rv_continuous* class, *dweibull* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *dweibull* is given by

$$f(x, c) = c/2|x|^{c-1} \exp(-|x|^c)$$

for a real number x and $c > 0$.

dweibull takes `c` as a shape parameter for c.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `dweibull.pdf(x, c, loc, scale)` is identically equivalent to `dweibull.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import dweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 2.07
>>> mean, var, skew, kurt = dweibull.stats(c, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(dweibull.ppf(0.01, c),
...                 dweibull.ppf(0.99, c), 100)
>>> ax.plot(x, dweibull.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='dweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = dweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

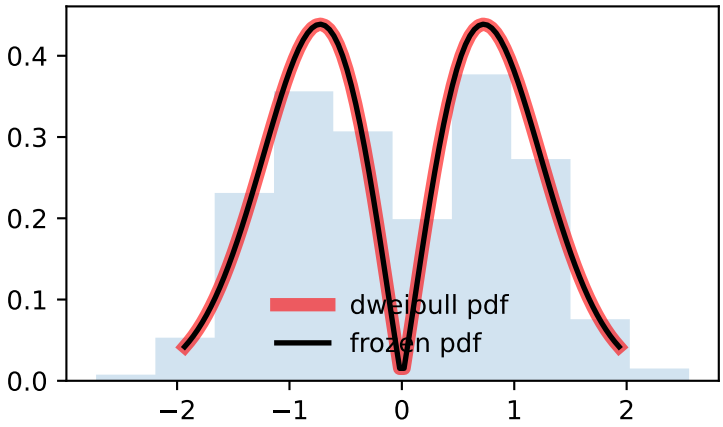
```
>>> vals = dweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], dweibull.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = dweibull.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, loc=0, scale=1)	Probability density function.
logpdf(x, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, c, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, c, loc=0, scale=1)	Log of the survival function.
ppf(q, c, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, c, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, c, loc=0, scale=1)	Non-central moment of order n
stats(c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(c, loc=0, scale=1)	Median of the distribution.
mean(c, loc=0, scale=1)	Mean of the distribution.
var(c, loc=0, scale=1)	Variance of the distribution.
std(c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.erlang

scipy.stats.**erlang = <scipy.stats._continuous_distns.erlang_gen object>**

An Erlang continuous random variable.

As an instance of the *rv_continuous* class, *erlang* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

gamma

Notes

The Erlang distribution is a special case of the Gamma distribution, with the shape parameter a an integer. Note that this restriction is not enforced by *erlang*. It will, however, generate a warning the first time a non-integer value is used for the shape parameter.

Refer to *gamma* for examples.

Methods

rvs(a, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, a, loc=0, scale=1)	Probability density function.
logpdf(x, a, loc=0, scale=1)	Log of the probability density function.
cdf(x, a, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, a, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, a, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, a, loc=0, scale=1)	Log of the survival function.
ppf(q, a, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, a, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, a, loc=0, scale=1)	Non-central moment of order n
stats(a, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(a, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(a, loc=0, scale=1)	Median of the distribution.
mean(a, loc=0, scale=1)	Mean of the distribution.
var(a, loc=0, scale=1)	Variance of the distribution.
std(a, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, a, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.expon

scipy.stats.**expon = <scipy.stats._continuous_distns.expon_gen object>**

An exponential continuous random variable.

As an instance of the *rv_continuous* class, *expon* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *expon* is:

$$f(x) = \exp(-x)$$

for $x \geq 0$.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `expon.pdf(x, loc, scale)` is identically equivalent to `expon.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

A common parameterization for *expon* is in terms of the rate parameter `lambda`, such that `pdf = lambda * exp(-lambda * x)`. This parameterization corresponds to using `scale = 1 / lambda`.

The exponential distribution is a special case of the gamma distributions, with gamma shape parameter `a = 1`.

Examples

```
>>> from scipy.stats import expon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = expon.stats(moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(expon.ppf(0.01),
...                 expon.ppf(0.99), 100)
>>> ax.plot(x, expon.pdf(x),
...         'r-', lw=5, alpha=0.6, label='expon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = expon()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

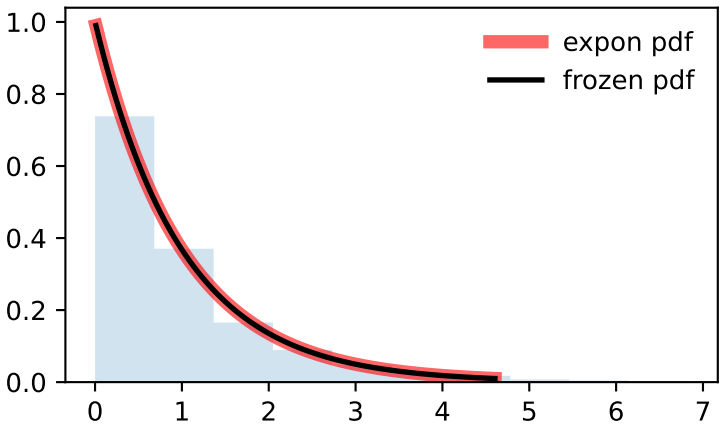
```
>>> vals = expon.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], expon.cdf(vals))
True
```

Generate random numbers:

```
>>> r = expon.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, loc=0, scale=1)	Probability density function.
logpdf(x, loc=0, scale=1)	Log of the probability density function.
cdf(x, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, loc=0, scale=1)	Log of the survival function.
ppf(q, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, loc=0, scale=1)	Non-central moment of order n
stats(loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(loc=0, scale=1)	Median of the distribution.
mean(loc=0, scale=1)	Mean of the distribution.
var(loc=0, scale=1)	Variance of the distribution.
std(loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.exponnorm

scipy.stats.**exponnorm = <scipy.stats._continuous_distns.exponnorm_gen object>**

An exponentially modified Normal continuous random variable.

Also known as the exponentially modified Gaussian distribution [1].

As an instance of the *rv_continuous* class, *exponnorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *exponnorm* is:

$$f(x, K) = \frac{1}{2K} \exp\left(\frac{1}{2K^2} - x/K\right) \operatorname{erfc}\left(-\frac{x - 1/K}{\sqrt{2}}\right)$$

where x is a real number and $K > 0$.

It can be thought of as the sum of a standard normal random variable and an independent exponentially distributed random variable with rate `1/K`.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponnorm.pdf(x, K, loc, scale)` is identically equivalent

to `exponnorm.pdf(y, K) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

An alternative parameterization of this distribution (for example, in the Wikpedia article [1]) involves three parameters, μ, λ and σ.

In the present parameterization this corresponds to having `loc` and `scale` equal to μ and σ, respectively, and shape parameter $K = 1/(\sigma\lambda)$.

New in version 0.16.0.

References

[1]

Examples

```
>>> from scipy.stats import exponnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> K = 1.5
>>> mean, var, skew, kurt = exponnorm.stats(K, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(exponnorm.ppf(0.01, K),
...                 exponnorm.ppf(0.99, K), 100)
>>> ax.plot(x, exponnorm.pdf(x, K),
...         'r-', lw=5, alpha=0.6, label='exponnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = exponnorm(K)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

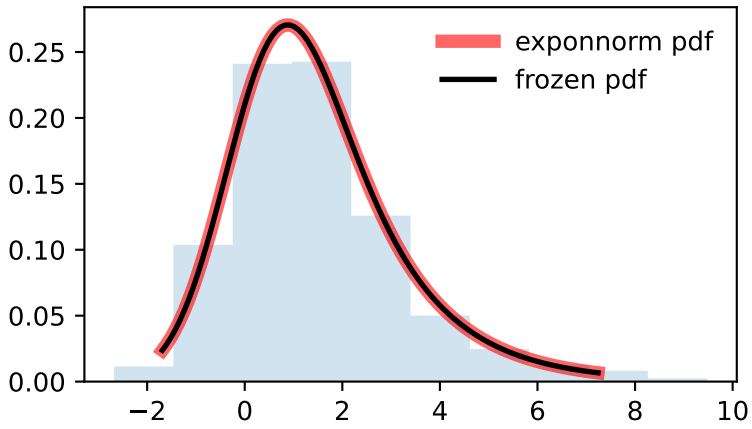
```
>>> vals = exponnorm.ppf([0.001, 0.5, 0.999], K)
>>> np.allclose([0.001, 0.5, 0.999], exponnorm.cdf(vals, K))
True
```

Generate random numbers:

```
>>> r = exponnorm.rvs(K, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(K, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, K, loc=0, scale=1)	Probability density function.
logpdf(x, K, loc=0, scale=1)	Log of the probability density function.
cdf(x, K, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, K, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, K, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, K, loc=0, scale=1)	Log of the survival function.
ppf(q, K, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, K, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, K, loc=0, scale=1)	Non-central moment of order n
stats(K, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(K, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(K,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(K, loc=0, scale=1)	Median of the distribution.

var(K, loc=0, scale=1)	Variance of the distribution.
std(K, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, K, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.exponweib

scipy.stats.**exponweib = <scipy.stats._continuous_distns.exponweib_gen object>**

An exponentiated Weibull continuous random variable.

As an instance of the *rv_continuous* class, *exponweib* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

weibull_min, ***numpy.random.Generator.weibull***

Notes

The probability density function for *exponweib* is:

$$f(x, a, c) = ac[1 - \exp(-x^c)]^{a-1} \exp(-x^c)x^{c-1}$$

and its cumulative distribution function is:

$$F(x, a, c) = [1 - \exp(-x^c)]^a$$

for $x > 0$, $a > 0$, $c > 0$.

exponweib takes a and c as shape parameters:

- a is the exponentiation parameter, with the special case $a = 1$ corresponding to the (non-exponentiated) Weibull distribution *weibull_min*.
- c is the shape parameter of the non-exponentiated Weibull law.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponweib.pdf(x, a, c, loc, scale)` is identically equivalent to `exponweib.pdf(y, a, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

References

https://en.wikipedia.org/wiki/Exponentiated_Weibull_distribution

Examples

```
>>> from scipy.stats import exponweib
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, c = 2.89, 1.95
>>> mean, var, skew, kurt = exponweib.stats(a, c, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(exponweib.ppf(0.01, a, c),
...                 exponweib.ppf(0.99, a, c), 100)
>>> ax.plot(x, exponweib.pdf(x, a, c),
...         'r-', lw=5, alpha=0.6, label='exponweib pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = exponweib(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

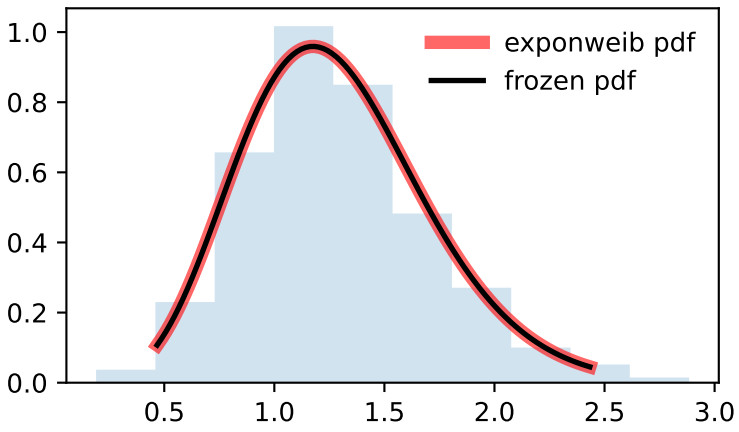
```
>>> vals = exponweib.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], exponweib.cdf(vals, a, c))
True
```

Generate random numbers:

```
>>> r = exponweib.rvs(a, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(a, c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, a, c, loc=0, scale=1)	Probability density function.
logpdf(x, a, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, a, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, a, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, a, c, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, a, c, loc=0, scale=1)	Log of the survival function.
ppf(q, a, c, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, a, c, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, a, c, loc=0, scale=1)	Non-central moment of order n
stats(a, c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(a, c, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(a, c), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(a, c, loc=0, scale=1)	Median of the distribution.
mean(a, c, loc=0, scale=1)	Mean of the distribution.
var(a, c, loc=0, scale=1)	Variance of the distribution.
std(a, c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, a, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.exponpow

scipy.stats.**exponpow = <scipy.stats._continuous_distns.exponpow_gen object>**

An exponential power continuous random variable.

As an instance of the *rv_continuous* class, *exponpow* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *exponpow* is:

$$f(x, b) = bx^{b-1} \exp(1 + x^b - \exp(x^b))$$

for $x \geq 0$, $b > 0$. Note that this is a different distribution from the exponential power distribution that is also known under the names "generalized normal" or "generalized Gaussian".

exponpow takes `b` as a shape parameter for b.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponpow.pdf(x, b, loc, scale)` is identically equivalent to `exponpow.pdf(y, b) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

References

http://www.math.wm.edu/~leemis/chart/UDR/PDFs/Exponentialpower.pdf

Examples

```
>>> from scipy.stats import exponpow
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> b = 2.7
>>> mean, var, skew, kurt = exponpow.stats(b, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(exponpow.ppf(0.01, b),
...                 exponpow.ppf(0.99, b), 100)
>>> ax.plot(x, exponpow.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='exponpow pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = exponpow(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

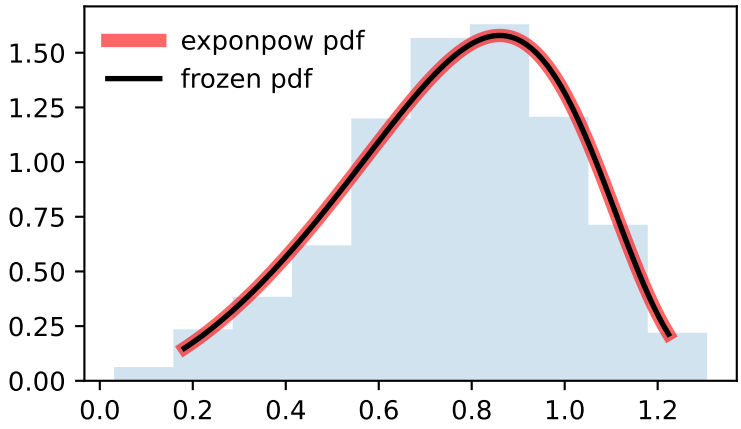
```
>>> vals = exponpow.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], exponpow.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = exponpow.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(b, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, b, loc=0, scale=1)	Probability density function.
logpdf(x, b, loc=0, scale=1)	Log of the probability density function.
cdf(x, b, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, b, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, b, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, b, loc=0, scale=1)	Log of the survival function.
ppf(q, b, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, b, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, b, loc=0, scale=1)	Non-central moment of order n
stats(b, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(b, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(b,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(b, loc=0, scale=1)	Median of the distribution.
mean(b, loc=0, scale=1)	Mean of the distribution.
var(b, loc=0, scale=1)	Variance of the distribution.
std(b, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, b, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.f

scipy.stats.**f = <scipy.stats._continuous_distns.f_gen object>**

An F continuous random variable.

For the noncentral F distribution, see *ncf*.

As an instance of the *rv_continuous* class, *f* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

ncf

Notes

The probability density function for *f* is:

$$f(x, df_1, df_2) = \frac{df_2^{df_2/2} df_1^{df_1/2} x^{df_1/2-1}}{(df_2 + df_1 x)^{(df_1+df_2)/2} B(df_1/2, df_2/2)}$$

for $x > 0$.

f takes `dfn` and `dfd` as shape parameters.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `f.pdf(x, dfn, dfd, loc, scale)` is identically equivalent to `f.pdf(y, dfn, dfd) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import f
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> dfn, dfd = 29, 18
>>> mean, var, skew, kurt = f.stats(dfn, dfd, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(f.ppf(0.01, dfn, dfd),
...                 f.ppf(0.99, dfn, dfd), 100)
>>> ax.plot(x, f.pdf(x, dfn, dfd),
...         'r-', lw=5, alpha=0.6, label='f pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = f(dfn, dfd)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

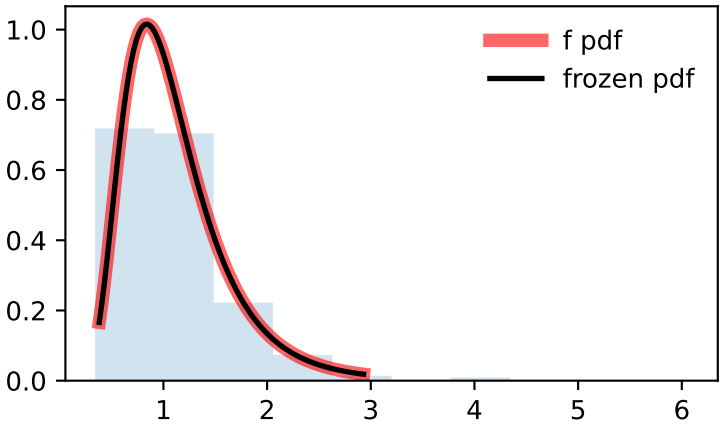
```
>>> vals = f.ppf([0.001, 0.5, 0.999], dfn, dfd)
>>> np.allclose([0.001, 0.5, 0.999], f.cdf(vals, dfn, dfd))
True
```

Generate random numbers:

```
>>> r = f.rvs(dfn, dfd, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(dfn, dfd, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, dfn, dfd, loc=0, scale=1)	Probability density function.
logpdf(x, dfn, dfd, loc=0, scale=1)	Log of the probability density function.
cdf(x, dfn, dfd, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, dfn, dfd, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, dfn, dfd, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, dfn, dfd, loc=0, scale=1)	Log of the survival function.
ppf(q, dfn, dfd, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, dfn, dfd, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, dfn, dfd, loc=0, scale=1)	Non-central moment of order n
stats(dfn, dfd, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(dfn, dfd, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(dfn, dfd), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(dfn, dfd, loc=0, scale=1)	Median of the distribution.
mean(dfn, dfd, loc=0, scale=1)	Mean of the distribution.
var(dfn, dfd, loc=0, scale=1)	Variance of the distribution.
std(dfn, dfd, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, dfn, dfd, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.fatiguelife

scipy.stats.**fatiguelife = <scipy.stats._continuous_distns.fatiguelife_gen object>**

A fatigue-life (Birnbaum-Saunders) continuous random variable.

As an instance of the *rv_continuous* class, *fatiguelife* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *fatiguelife* is:

$$f(x, c) = \frac{x+1}{2c\sqrt{2\pi x^3}} \exp(-\frac{(x-1)^2}{2xc^2})$$

for $x >= 0$ and $c > 0$.

fatiguelife takes `c` as a shape parameter for c.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `fatiguelife.pdf(x, c, loc, scale)` is identically equivalent to `fatiguelife.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that

shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1]

Examples

```
>>> from scipy.stats import fatiguelife
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 29
>>> mean, var, skew, kurt = fatiguelife.stats(c, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(fatiguelife.ppf(0.01, c),
...                 fatiguelife.ppf(0.99, c), 100)
>>> ax.plot(x, fatiguelife.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='fatiguelife pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = fatiguelife(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

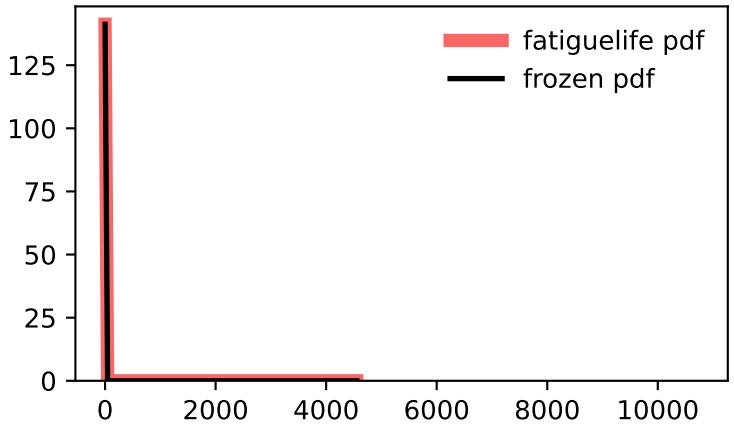
```
>>> vals = fatiguelife.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fatiguelife.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = fatiguelife.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, loc=0, scale=1)	Probability density function.
logpdf(x, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, c, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, c, loc=0, scale=1)	Log of the survival function.
ppf(q, c, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, c, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, c, loc=0, scale=1)	Non-central moment of order n
stats(c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, loc=0, scale=1)	(Differential) entropy of the RV.

mean(c, loc=0, scale=1)	Mean of the distribution.
var(c, loc=0, scale=1)	Variance of the distribution.
std(c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.fisk

scipy.stats.**fisk = <scipy.stats._continuous_distns.fisk_gen object>**

A Fisk continuous random variable.

The Fisk distribution is also known as the log-logistic distribution.

As an instance of the *rv_continuous* class, *fisk* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

burr

Notes

The probability density function for *fisk* is:

$$f(x, c) = cx^{-c-1}(1 + x^{-c})^{-2}$$

for $x >= 0$ and $c > 0$.

fisk takes `c` as a shape parameter for c.

fisk is a special case of *burr* or *burr12* with `d=1`.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `fisk.pdf(x, c, loc, scale)` is identically equivalent to `fisk.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import fisk
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 3.09
>>> mean, var, skew, kurt = fisk.stats(c, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(fisk.ppf(0.01, c),
...                 fisk.ppf(0.99, c), 100)
>>> ax.plot(x, fisk.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='fisk pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = fisk(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

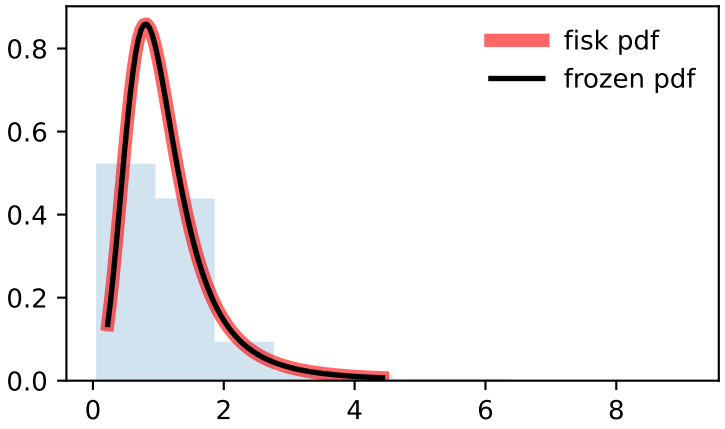
```
>>> vals = fisk.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fisk.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = fisk.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, loc=0, scale=1)	Probability density function.
logpdf(x, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, c, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, c, loc=0, scale=1)	Log of the survival function.
ppf(q, c, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, c, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, c, loc=0, scale=1)	Non-central moment of order n
stats(c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(c, loc=0, scale=1)	Median of the distribution.
mean(c, loc=0, scale=1)	Mean of the distribution.
var(c, loc=0, scale=1)	Variance of the distribution.
std(c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.foldcauchy

scipy.stats.**foldcauchy = <scipy.stats._continuous_distns.foldcauchy_gen object>**

A folded Cauchy continuous random variable.

As an instance of the *rv_continuous* class, *foldcauchy* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *foldcauchy* is:

$$f(x, c) = \frac{1}{\pi(1 + (x - c)^2)} + \frac{1}{\pi(1 + (x + c)^2)}$$

for $x \geq 0$.

foldcauchy takes `c` as a shape parameter for c.

Examples

```
>>> from scipy.stats import foldcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 4.72
>>> mean, var, skew, kurt = foldcauchy.stats(c, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(foldcauchy.ppf(0.01, c),
...                 foldcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, foldcauchy.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='foldcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = foldcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

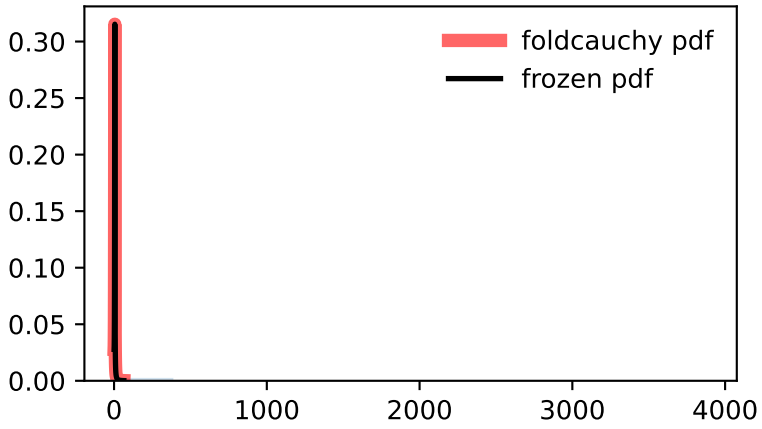
```
>>> vals = foldcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldcauchy.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = foldcauchy.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, loc=0, scale=1)	Probability density function.
logpdf(x, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, c, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, c, loc=0, scale=1)	Log of the survival function.
ppf(q, c, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, c, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, c, loc=0, scale=1)	Non-central moment of order n
stats(c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(c, loc=0, scale=1)	Median of the distribution.
mean(c, loc=0, scale=1)	Mean of the distribution.
var(c, loc=0, scale=1)	Variance of the distribution.
std(c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.foldnorm

scipy.stats.**foldnorm = <scipy.stats._continuous_distns.foldnorm_gen object>**

A folded normal continuous random variable.

As an instance of the *rv_continuous* class, *foldnorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *foldnorm* is:

$$f(x, c) = \sqrt{2/\pi} cosh(cx) \exp(-\frac{x^2+c^2}{2})$$

for $c \geq 0$.

foldnorm takes `c` as a shape parameter for c.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `foldnorm.pdf(x, c, loc, scale)` is identically equivalent to `foldnorm.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import foldnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 1.95
>>> mean, var, skew, kurt = foldnorm.stats(c, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(foldnorm.ppf(0.01, c),
...                 foldnorm.ppf(0.99, c), 100)
>>> ax.plot(x, foldnorm.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='foldnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = foldnorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

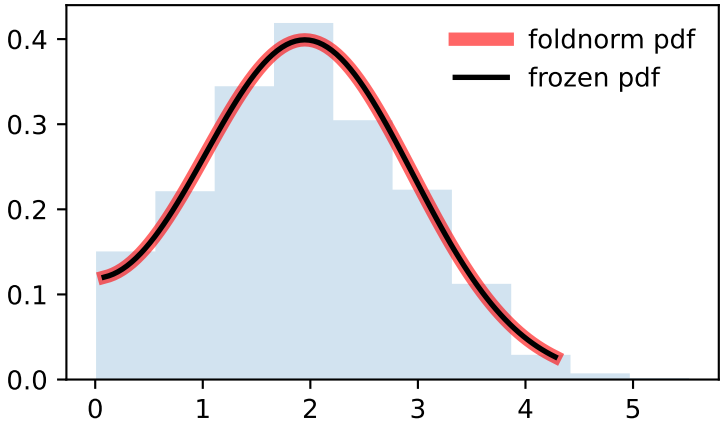
```
>>> vals = foldnorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldnorm.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = foldnorm.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, loc=0, scale=1)	Probability density function.
logpdf(x, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, c, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, c, loc=0, scale=1)	Log of the survival function.
ppf(q, c, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, c, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, c, loc=0, scale=1)	Non-central moment of order n
stats(c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(c, loc=0, scale=1)	Median of the distribution.
mean(c, loc=0, scale=1)	Mean of the distribution.
var(c, loc=0, scale=1)	Variance of the distribution.
std(c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.genlogistic

scipy.stats.**genlogistic = <scipy.stats._continuous_distns.genlogistic_gen object>**

A generalized logistic continuous random variable.

As an instance of the *rv_continuous* class, *genlogistic* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *genlogistic* is:

$$f(x, c) = c\frac{\exp(-x)}{(1+\exp(-x))^{c+1}}$$

for $x >= 0$, $c > 0$.

genlogistic takes `c` as a shape parameter for c.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genlogistic.pdf(x, c, loc, scale)` is identically equivalent to `genlogistic.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import genlogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.412
>>> mean, var, skew, kurt = genlogistic.stats(c, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(genlogistic.ppf(0.01, c),
...                 genlogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genlogistic.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='genlogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = genlogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

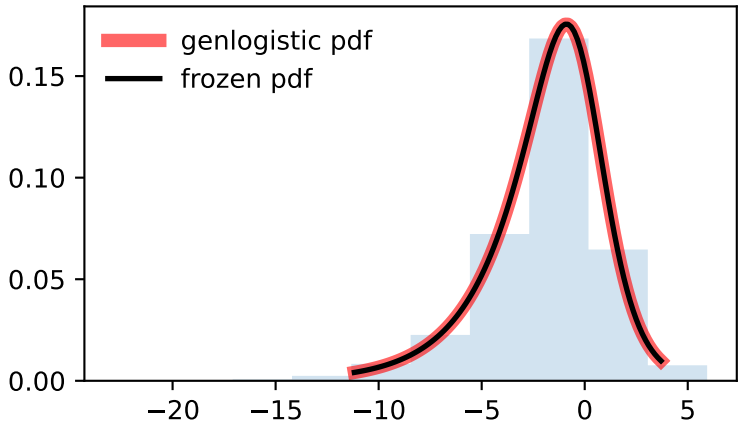
```
>>> vals = genlogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genlogistic.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genlogistic.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, loc=0, scale=1)	Probability density function.
logpdf(x, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, c, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, c, loc=0, scale=1)	Log of the survival function.
ppf(q, c, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, c, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, c, loc=0, scale=1)	Non-central moment of order n
stats(c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(c, loc=0, scale=1)	Median of the distribution.
mean(c, loc=0, scale=1)	Mean of the distribution.
var(c, loc=0, scale=1)	Variance of the distribution.
std(c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.gennorm

scipy.stats.**gennorm = <scipy.stats._continuous_distns.gennorm_gen object>**

A generalized normal continuous random variable.

As an instance of the *rv_continuous* class, *gennorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

laplace

Laplace distribution

norm

normal distribution

Notes

The probability density function for *gennorm* is [1]:

$$f(x, \beta) = \frac{\beta}{2\Gamma(1/\beta)} \exp(-|x|^\beta)$$

Γ is the gamma function (*scipy.special.gamma*).

gennorm takes `beta` as a shape parameter for β. For $\beta = 1$, it is identical to a Laplace distribution. For $\beta = 2$, it is identical to a normal distribution (with `scale=1/sqrt(2)`).

References

[1]

Examples

```
>>> from scipy.stats import gennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> beta = 1.3
>>> mean, var, skew, kurt = gennorm.stats(beta, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(gennorm.ppf(0.01, beta),
...                 gennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, gennorm.pdf(x, beta),
...         'r-', lw=5, alpha=0.6, label='gennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = gennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

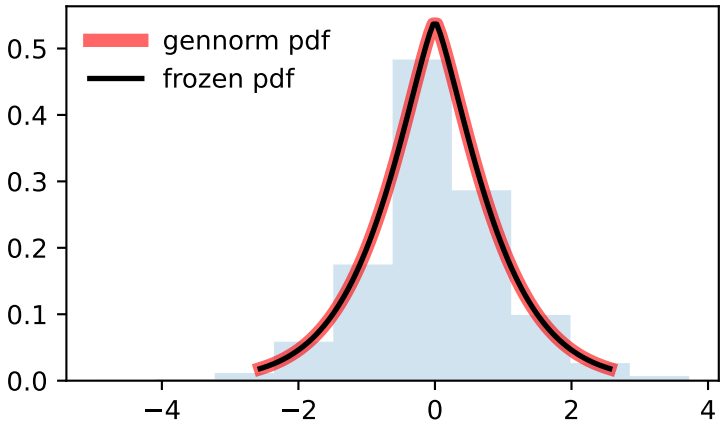
```
>>> vals = gennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], gennorm.cdf(vals, beta))
True
```

Generate random numbers:

```
>>> r = gennorm.rvs(beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(beta, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, beta, loc=0, scale=1)	Probability density function.
logpdf(x, beta, loc=0, scale=1)	Log of the probability density function.
cdf(x, beta, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, beta, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, beta, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, beta, loc=0, scale=1)	Log of the survival function.
ppf(q, beta, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, beta, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, beta, loc=0, scale=1)	Non-central moment of order n
stats(beta, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(beta, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(beta,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(beta, loc=0, scale=1)	Median of the distribution.
mean(beta, loc=0, scale=1)	Mean of the distribution.
var(beta, loc=0, scale=1)	Variance of the distribution.
std(beta, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, beta, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.genpareto

scipy.stats.**genpareto = <scipy.stats._continuous_distns.genpareto_gen object>**

A generalized Pareto continuous random variable.

As an instance of the *rv_continuous* class, *genpareto* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *genpareto* is:

$$f(x, c) = (1 + cx)^{-1-1/c}$$

defined for $x \geq 0$ if $c \geq 0$, and for $0 \leq x \leq -1/c$ if $c < 0$.

genpareto takes `c` as a shape parameter for c.

For $c = 0$, *genpareto* reduces to the exponential distribution, *expon*:

$$f(x, 0) = \exp(-x)$$

For $c = -1$, *genpareto* is uniform on `[0, 1]`:

$$f(x, -1) = 1$$

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genpareto.pdf(x, c, loc, scale)` is identically equivalent to `genpareto.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import genpareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.1
>>> mean, var, skew, kurt = genpareto.stats(c, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(genpareto.ppf(0.01, c),
...                 genpareto.ppf(0.99, c), 100)
>>> ax.plot(x, genpareto.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='genpareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = genpareto(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

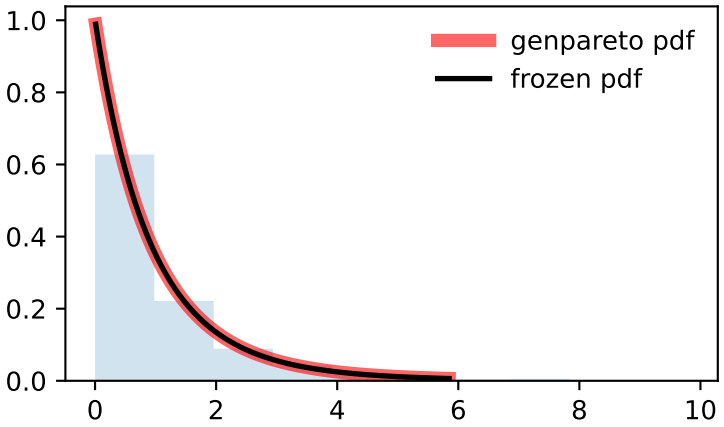
```
>>> vals = genpareto.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genpareto.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genpareto.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, loc=0, scale=1)	Probability density function.
logpdf(x, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, c, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, c, loc=0, scale=1)	Log of the survival function.
ppf(q, c, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, c, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, c, loc=0, scale=1)	Non-central moment of order n
stats(c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(c, loc=0, scale=1)	Median of the distribution.
mean(c, loc=0, scale=1)	Mean of the distribution.
var(c, loc=0, scale=1)	Variance of the distribution.
std(c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.genexpon

scipy.stats.**genexpon = <scipy.stats._continuous_distns.genexpon_gen object>**

A generalized exponential continuous random variable.

As an instance of the *rv_continuous* class, *genexpon* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *genexpon* is:

$$f(x, a, b, c) = (a + b(1 - \exp(-cx))) \exp(-ax - bx + \frac{b}{c}(1 - \exp(-cx)))$$

for $x \geq 0$, $a, b, c > 0$.

genexpon takes a, b and c as shape parameters.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genexpon.pdf(x, a, b, c, loc, scale)` is identically equivalent to `genexpon.pdf(y, a, b, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import genexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b, c = 9.13, 16.2, 3.28
>>> mean, var, skew, kurt = genexpon.stats(a, b, c, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(genexpon.ppf(0.01, a, b, c),
...                 genexpon.ppf(0.99, a, b, c), 100)
>>> ax.plot(x, genexpon.pdf(x, a, b, c),
...         'r-', lw=5, alpha=0.6, label='genexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = genexpon(a, b, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

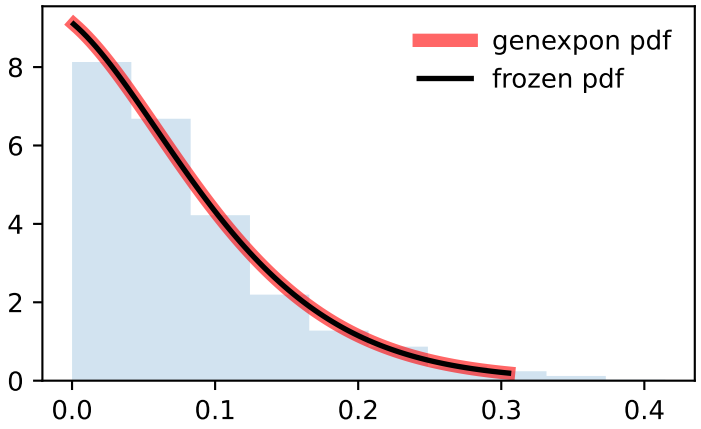
```
>>> vals = genexpon.ppf([0.001, 0.5, 0.999], a, b, c)
>>> np.allclose([0.001, 0.5, 0.999], genexpon.cdf(vals, a, b, c))
True
```

Generate random numbers:

```
>>> r = genexpon.rvs(a, b, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(a, b, c, loc=0, scale=1, size=1, random_state=None)	Random variates.

interval(alpha, a, b, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.genextreme

scipy.stats.**genextreme = <scipy.stats._continuous_distns.genextreme_gen object>**

A generalized extreme value continuous random variable.

As an instance of the *rv_continuous* class, *genextreme* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

gumbel_r

Notes

For $c = 0$, *genextreme* is equal to *gumbel_r*. The probability density function for *genextreme* is:

$$f(x, c) = \begin{cases} \exp(-\exp(-x))\exp(-x) & \text{for } c = 0 \\ \exp(-(1-cx)^{1/c})(1-cx)^{1/c-1} & \text{for } x \le 1/c, c > 0 \end{cases}$$

Note that several sources and software packages use the opposite convention for the sign of the shape parameter c.

genextreme takes `c` as a shape parameter for c.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genextreme.pdf(x, c, loc, scale)` is identically equivalent to `genextreme.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import genextreme
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = -0.1
>>> mean, var, skew, kurt = genextreme.stats(c, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(genextreme.ppf(0.01, c),
...                 genextreme.ppf(0.99, c), 100)
>>> ax.plot(x, genextreme.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='genextreme pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = genextreme(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

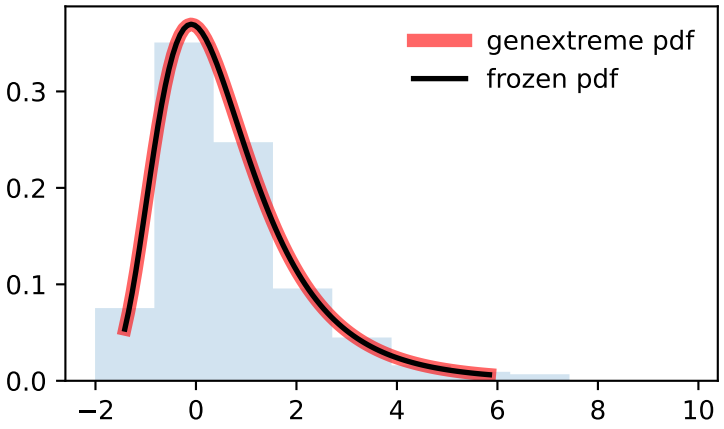
```
>>> vals = genextreme.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genextreme.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genextreme.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, loc=0, scale=1)	Probability density function.
logpdf(x, c, loc=0, scale=1)	Log of the probability density function.

std(c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.gausshyper

scipy.stats.**gausshyper = <scipy.stats._continuous_distns.gausshyper_gen object>**

A Gauss hypergeometric continuous random variable.

As an instance of the *rv_continuous* class, *gausshyper* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *gausshyper* is:

$$f(x, a, b, c, z) = Cx^{a-1}(1-x)^{b-1}(1+zx)^{-c}$$

for $0 \leq x \leq 1$, $a > 0$, $b > 0$, $z > -1$, and $C = \frac{1}{B(a,b)F[2,1](c,a;a+b;-z)}$. $F[2,1]$ is the Gauss hypergeometric function *scipy.special.hyp2f1*.

gausshyper takes a, b, c and z as shape parameters.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gausshyper.pdf(x, a, b, c, z, loc, scale)` is identically equivalent to `gausshyper.pdf(y, a, b, c, z) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1]

Examples

```
>>> from scipy.stats import gausshyper
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b, c, z = 13.8, 3.12, 2.51, 5.18
>>> mean, var, skew, kurt = gausshyper.stats(a, b, c, z, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(gausshyper.ppf(0.01, a, b, c, z),
...                 gausshyper.ppf(0.99, a, b, c, z), 100)
>>> ax.plot(x, gausshyper.pdf(x, a, b, c, z),
...         'r-', lw=5, alpha=0.6, label='gausshyper pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = gausshyper(a, b, c, z)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

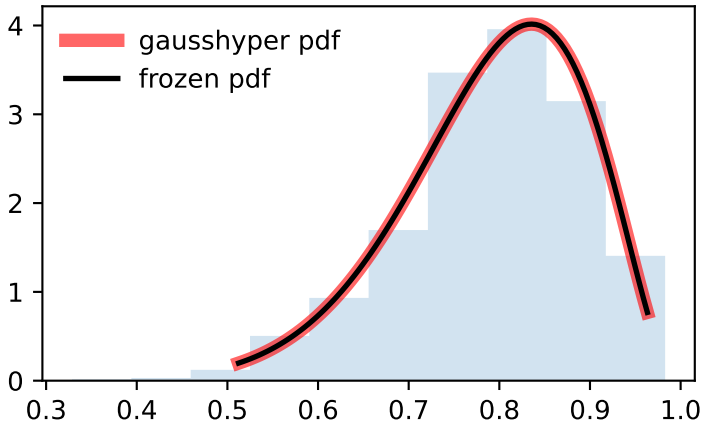
```
>>> vals = gausshyper.ppf([0.001, 0.5, 0.999], a, b, c, z)
>>> np.allclose([0.001, 0.5, 0.999], gausshyper.cdf(vals, a, b, c, z))
True
```

Generate random numbers:

```
>>> r = gausshyper.rvs(a, b, c, z, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(a, b, c, z, loc=0, scale=1, size=1, random_state=None)	Random variates.

logpdf(x, a, b, c, z, loc=0, scale=1)	Log of the probability density function.
cdf(x, a, b, c, z, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, a, b, c, z, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, a, b, c, z, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, a, b, c, z, loc=0, scale=1)	Log of the survival function.
ppf(q, a, b, c, z, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, a, b, c, z, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, a, b, c, z, loc=0, scale=1)	Non-central moment of order n
stats(a, b, c, z, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(a, b, c, z, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(a, b, c, z), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(a, b, c, z, loc=0, scale=1)	Median of the distribution.
mean(a, b, c, z, loc=0, scale=1)	Mean of the distribution.
var(a, b, c, z, loc=0, scale=1)	Variance of the distribution.
std(a, b, c, z, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, a, b, c, z, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.gamma

scipy.stats.**gamma = <scipy.stats._continuous_distns.gamma_gen object>**

A gamma continuous random variable.

As an instance of the *rv_continuous* class, *gamma* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

erlang, **expon**

Notes

The probability density function for *gamma* is:

$$f(x, a) = \frac{x^{a-1} e^{-x}}{\Gamma(a)}$$

for $x \geq 0$, $a > 0$. Here $\Gamma(a)$ refers to the gamma function.

gamma takes `a` as a shape parameter for a.

When a is an integer, *gamma* reduces to the Erlang distribution, and when $a = 1$ to the exponential distribution.

Gamma distributions are sometimes parameterized with two variables, with a probability density function of:

$$f(x, \alpha, \beta) = \frac{\beta^{\alpha} x^{\alpha-1} e^{-\beta x}}{\Gamma(\alpha)}$$

Note that this parameterization is equivalent to the above, with `scale = 1 / beta`.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gamma.pdf(x, a, loc, scale)` is identically equivalent to `gamma.pdf(y, a) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import gamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 1.99
>>> mean, var, skew, kurt = gamma.stats(a, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(gamma.ppf(0.01, a),
...                 gamma.ppf(0.99, a), 100)
>>> ax.plot(x, gamma.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='gamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = gamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

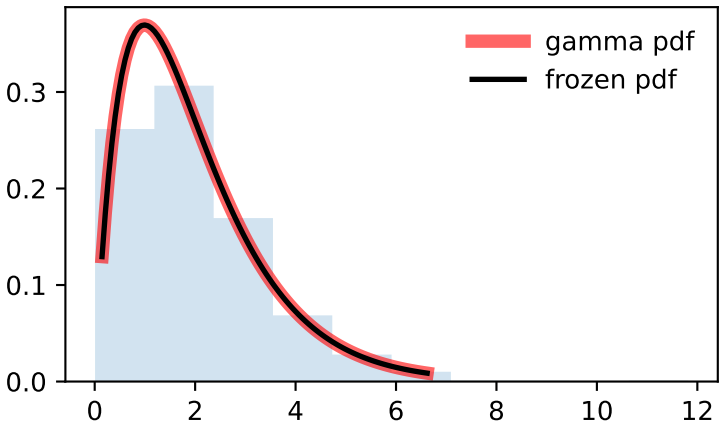
```
>>> vals = gamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], gamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = gamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(a, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, a, loc=0, scale=1)	Probability density function.
logpdf(x, a, loc=0, scale=1)	Log of the probability density function.
cdf(x, a, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, a, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, a, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, a, loc=0, scale=1)	Log of the survival function.
ppf(q, a, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, a, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, a, loc=0, scale=1)	Non-central moment of order n
stats(a, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(a, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(a, loc=0, scale=1)	Median of the distribution.
mean(a, loc=0, scale=1)	Mean of the distribution.
var(a, loc=0, scale=1)	Variance of the distribution.
std(a, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, a, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.gengamma

scipy.stats.**gengamma = <scipy.stats._continuous_distns.gengamma_gen object>**

A generalized gamma continuous random variable.

As an instance of the *rv_continuous* class, *gengamma* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

gamma, **invgamma**, **weibull_min**

Notes

The probability density function for *gengamma* is ([1]):

$$f(x, a, c) = \frac{|c| x^{ca-1} \exp(-x^c)}{\Gamma(a)}$$

for $x \geq 0$, $a > 0$, and $c \neq 0$. Γ is the gamma function (*scipy.special.gamma*).

gengamma takes a and c as shape parameters.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gengamma.pdf(x, a, c, loc, scale)` is identically equivalent to `gengamma.pdf(y, a, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1]

Examples

```
>>> from scipy.stats import gengamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, c = 4.42, -3.12
>>> mean, var, skew, kurt = gengamma.stats(a, c, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(gengamma.ppf(0.01, a, c),
...                 gengamma.ppf(0.99, a, c), 100)
>>> ax.plot(x, gengamma.pdf(x, a, c),
...         'r-', lw=5, alpha=0.6, label='gengamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = gengamma(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

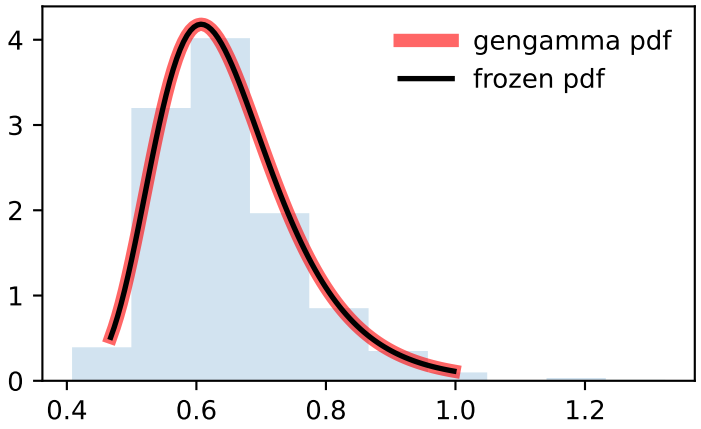
```
>>> vals = gengamma.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], gengamma.cdf(vals, a, c))
True
```

Generate random numbers:

```
>>> r = gengamma.rvs(a, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(a, c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, a, c, loc=0, scale=1)	Probability density function.
logpdf(x, a, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, a, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, a, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, a, c, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, a, c, loc=0, scale=1)	Log of the survival function.
ppf(q, a, c, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, a, c, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, a, c, loc=0, scale=1)	Non-central moment of order n
stats(a, c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(a, c, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(a, c), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(a, c, loc=0, scale=1)	Median of the distribution.
mean(a, c, loc=0, scale=1)	Mean of the distribution.
var(a, c, loc=0, scale=1)	Variance of the distribution.
std(a, c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, a, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.genhalflogistic

scipy.stats.**genhalflogistic = <scipy.stats._continuous_distns.genhalflogistic_gen object>**

A generalized half-logistic continuous random variable.

As an instance of the *rv_continuous* class, *genhalflogistic* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *genhalflogistic* is:

$$f(x, c) = \frac{2(1 - cx)^{1/(c-1)}}{[1 + (1 - cx)^{1/c}]^2}$$

for $0 \leq x \leq 1/c$, and $c > 0$.

genhalflogistic takes `c` as a shape parameter for c.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genhalflogistic.pdf(x, c, loc, scale)` is identically equivalent to `genhalflogistic.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import genhalflogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.773
>>> mean, var, skew, kurt = genhalflogistic.stats(c, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(genhalflogistic.ppf(0.01, c),
...                 genhalflogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genhalflogistic.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='genhalflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = genhalflogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

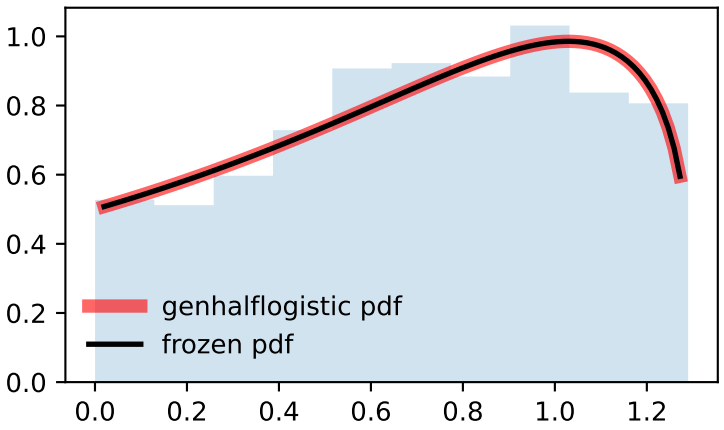
```
>>> vals = genhalflogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genhalflogistic.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genhalflogistic.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, loc=0, scale=1)	Probability density function.
logpdf(x, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, c, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, c, loc=0, scale=1)	Log of the survival function.
ppf(q, c, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, c, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, c, loc=0, scale=1)	Non-central moment of order n
stats(c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(c, loc=0, scale=1)	Median of the distribution.
mean(c, loc=0, scale=1)	Mean of the distribution.
var(c, loc=0, scale=1)	Variance of the distribution.
std(c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.genhyperbolic

scipy.stats.**genhyperbolic = <scipy.stats._continuous_distns.genhyperbolic_gen object>**

A generalized hyperbolic continuous random variable.

As an instance of the *rv_continuous* class, *genhyperbolic* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

t, **norminvgauss**, **geninvgauss**, **laplace**, **cauchy**

Notes

The probability density function for *genhyperbolic* is:

$$f(x, p, a, b) = \frac{(a^2 - b^2)^{p/2}}{\sqrt{2\pi}a^{p-0.5}K_p\left(\sqrt{a^2 - b^2}\right)} e^{bx} \times \frac{K_{p-1/2}(a\sqrt{1+x^2})}{(\sqrt{1+x^2})^{1/2-p}}$$

for $x, p \in (-\infty; \infty)$, $|b| < a$ if $p \geq 0$, $|b| \leq a$ if $p < 0$. $K_p(.)$ denotes the modified Bessel function of the second kind and order p (*scipy.special.kn*)

genhyperbolic takes `p` as a tail parameter, `a` as a shape parameter, `b` as a skewness parameter.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genhyperbolic.pdf(x, p, a, b, loc, scale)` is identically equivalent to `genhyperbolic.pdf(y, p, a, b) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

The original parameterization of the Generalized Hyperbolic Distribution is found in [1] as follows

$$f(x, \lambda, \alpha, \beta, \delta, \mu) = \frac{(\gamma/\delta)^\lambda}{\sqrt{2\pi}K_\lambda(\delta\gamma)} e^{\beta(x-\mu)} \times \frac{K_{\lambda-1/2}(\alpha\sqrt{\delta^2+(x-\mu)^2})}{(\sqrt{\delta^2+(x-\mu)^2}/\alpha)^{1/2-\lambda}}$$

for $x \in (-\infty; \infty)$, $\gamma := \sqrt{\alpha^2 - \beta^2}$, $\lambda, \mu \in (-\infty; \infty)$, $\delta \geq 0, |\beta| < \alpha$ if $\lambda \geq 0$, $\delta > 0, |\beta| \leq \alpha$ if $\lambda < 0$.

The location-scale-based parameterization implemented in SciPy is based on [2], where $a = \alpha\delta$, $b = \beta\delta$, $p = \lambda$, $scale = \delta$ and $loc = \mu$

Moments are implemented based on [3] and [4].

For the distributions that are a special case such as Student's t, it is not recommended to rely on the implementation of genhyperbolic. To avoid potential numerical problems and for performance reasons, the methods of the specific distributions should be used.

References

[1], [2], [3], [4]

Examples

```
>>> from scipy.stats import genhyperbolic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> p, a, b = 0.5, 1.5, -0.5
>>> mean, var, skew, kurt = genhyperbolic.stats(p, a, b, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(genhyperbolic.ppf(0.01, p, a, b),
...                 genhyperbolic.ppf(0.99, p, a, b), 100)
>>> ax.plot(x, genhyperbolic.pdf(x, p, a, b),
...         'r-', lw=5, alpha=0.6, label='genhyperbolic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = genhyperbolic(p, a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

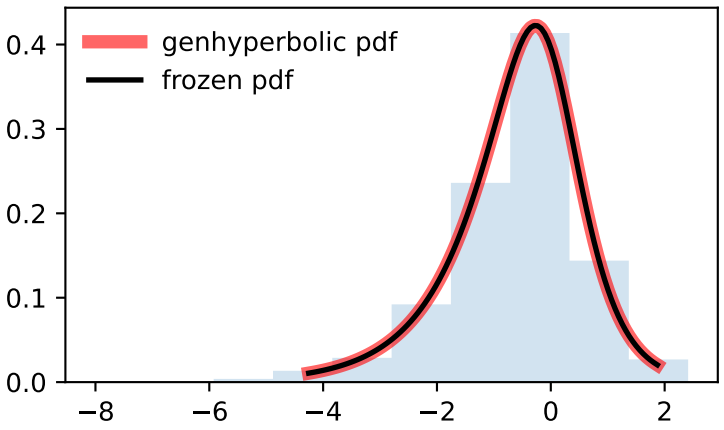
```
>>> vals = genhyperbolic.ppf([0.001, 0.5, 0.999], p, a, b)
>>> np.allclose([0.001, 0.5, 0.999], genhyperbolic.cdf(vals, p, a, b))
True
```

Generate random numbers:

```
>>> r = genhyperbolic.rvs(p, a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(p, a, b, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, p, a, b, loc=0, scale=1)	Probability density function.
logpdf(x, p, a, b, loc=0, scale=1)	Log of the probability density function.
cdf(x, p, a, b, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, p, a, b, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, p, a, b, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, p, a, b, loc=0, scale=1)	Log of the survival function.
ppf(q, p, a, b, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, p, a, b, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, p, a, b, loc=0, scale=1)	Non-central moment of order n
stats(p, a, b, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(p, a, b, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(p, a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(p, a, b, loc=0, scale=1)	Median of the distribution.
mean(p, a, b, loc=0, scale=1)	Mean of the distribution.
var(p, a, b, loc=0, scale=1)	Variance of the distribution.
std(p, a, b, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, p, a, b, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.geninvgauss

scipy.stats.**geninvgauss = <scipy.stats._continuous_distns.geninvgauss_gen object>**

A Generalized Inverse Gaussian continuous random variable.

As an instance of the *rv_continuous* class, *geninvgauss* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *geninvgauss* is:

$$f(x, p, b) = x^{p-1} \exp(-b(x + 1/x)/2)/(2K_p(b))$$

where $x > 0$, and the parameters p, b satisfy $b > 0$ ([1]). K_p is the modified Bessel function of second kind of order p (*scipy.special.kv*).

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `geninvgauss.pdf(x, p, b, loc, scale)` is identically equivalent to `geninvgauss.pdf(y, p, b) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

The inverse Gaussian distribution *stats.invgauss(mu)* is a special case of `geninvgauss` with *p = -1/2*, *b = 1 / mu* and *scale = mu*.

Generating random variates is challenging for this distribution. The implementation is based on [2].

References

[1], [2]

Examples

```
>>> from scipy.stats import geninvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> p, b = 2.3, 1.5
>>> mean, var, skew, kurt = geninvgauss.stats(p, b, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(geninvgauss.ppf(0.01, p, b),
...                 geninvgauss.ppf(0.99, p, b), 100)
>>> ax.plot(x, geninvgauss.pdf(x, p, b),
...         'r-', lw=5, alpha=0.6, label='geninvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = geninvgauss(p, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

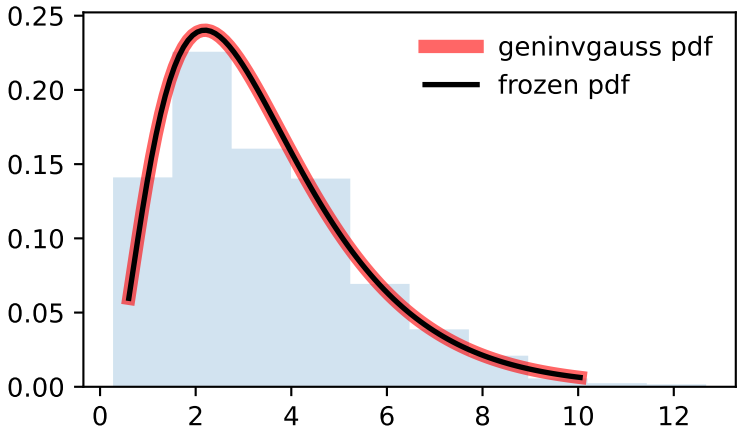
```
>>> vals = geninvgauss.ppf([0.001, 0.5, 0.999], p, b)
>>> np.allclose([0.001, 0.5, 0.999], geninvgauss.cdf(vals, p, b))
True
```

Generate random numbers:

```
>>> r = geninvgauss.rvs(p, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(p, b, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, p, b, loc=0, scale=1)	Probability density function.
logpdf(x, p, b, loc=0, scale=1)	Log of the probability density function.
cdf(x, p, b, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, p, b, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, p, b, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, p, b, loc=0, scale=1)	Log of the survival function.
ppf(q, p, b, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, p, b, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, p, b, loc=0, scale=1)	Non-central moment of order n
stats(p, b, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(p, b, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(p, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(p, b, loc=0, scale=1)	Median of the distribution.
mean(p, b, loc=0, scale=1)	Mean of the distribution.
var(p, b, loc=0, scale=1)	Variance of the distribution.
std(p, b, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, p, b, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.gilbrat

scipy.stats.**gilbrat = <scipy.stats._continuous_distns.gilbrat_gen object>**

A Gilbrat continuous random variable.

As an instance of the *rv_continuous* class, *gilbrat* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *gilbrat* is:

$$f(x) = \frac{1}{x\sqrt{2\pi}} \exp(-\frac{1}{2}(\log(x))^2)$$

gilbrat is a special case of *lognorm* with `s=1`.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gilbrat.pdf(x, loc, scale)` is identically equivalent to `gilbrat.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import gilbrat
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = gilbrat.stats(moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(gilbrat.ppf(0.01),
...                 gilbrat.ppf(0.99), 100)
>>> ax.plot(x, gilbrat.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gilbrat pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = gilbrat()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

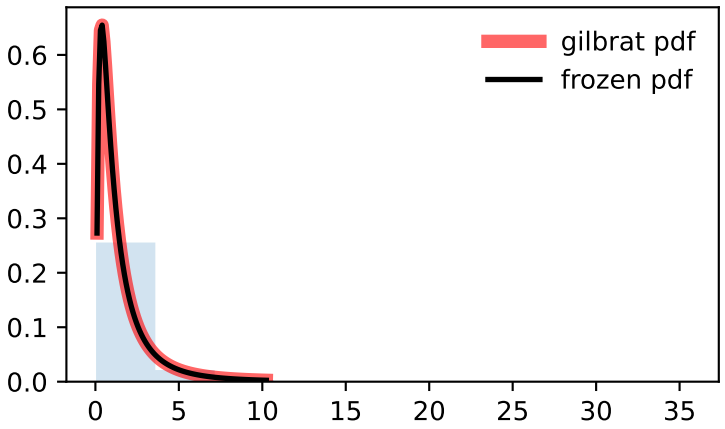
```
>>> vals = gilbrat.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gilbrat.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gilbrat.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, loc=0, scale=1)	Probability density function.
logpdf(x, loc=0, scale=1)	Log of the probability density function.
cdf(x, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, loc=0, scale=1)	Log of the survival function.
ppf(q, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, loc=0, scale=1)	Non-central moment of order n
stats(loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(loc=0, scale=1)	Median of the distribution.
mean(loc=0, scale=1)	Mean of the distribution.
var(loc=0, scale=1)	Variance of the distribution.
std(loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.gompertz

scipy.stats.**gompertz = <scipy.stats._continuous_distns.gompertz_gen object>**

A Gompertz (or truncated Gumbel) continuous random variable.

As an instance of the *rv_continuous* class, *gompertz* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *gompertz* is:

$$f(x, c) = c \exp(x) \exp(-c(e^x - 1))$$

for $x \geq 0$, $c > 0$.

gompertz takes `c` as a shape parameter for c.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gompertz.pdf(x, c, loc, scale)` is identically equivalent to `gompertz.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import gompertz
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.947
>>> mean, var, skew, kurt = gompertz.stats(c, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(gompertz.ppf(0.01, c),
...                 gompertz.ppf(0.99, c), 100)
>>> ax.plot(x, gompertz.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='gompertz pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = gompertz(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

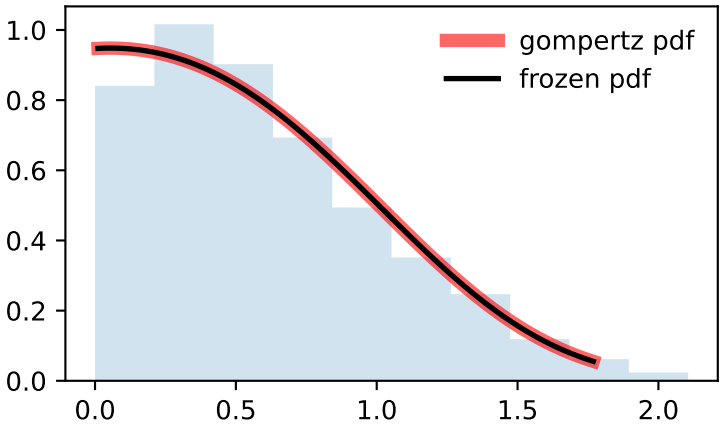
```
>>> vals = gompertz.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], gompertz.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = gompertz.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, loc=0, scale=1)	Probability density function.
logpdf(x, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, c, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, c, loc=0, scale=1)	Log of the survival function.
ppf(q, c, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, c, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, c, loc=0, scale=1)	Non-central moment of order n
stats(c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(c, loc=0, scale=1)	Median of the distribution.
mean(c, loc=0, scale=1)	Mean of the distribution.
var(c, loc=0, scale=1)	Variance of the distribution.
std(c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.gumbel_r

scipy.stats.**gumbel_r = <scipy.stats._continuous_distns.gumbel_r_gen object>**

A right-skewed Gumbel continuous random variable.

As an instance of the *rv_continuous* class, *gumbel_r* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

gumbel_l, **gompertz**, **genextreme**

Notes

The probability density function for *gumbel_r* is:

$$f(x) = \exp(-(x + e^{-x}))$$

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gumbel_r.pdf(x, loc, scale)` is identically equivalent to `gumbel_r.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import gumbel_r
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = gumbel_r.stats(moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(gumbel_r.ppf(0.01),
...                 gumbel_r.ppf(0.99), 100)
>>> ax.plot(x, gumbel_r.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gumbel_r pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = gumbel_r()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

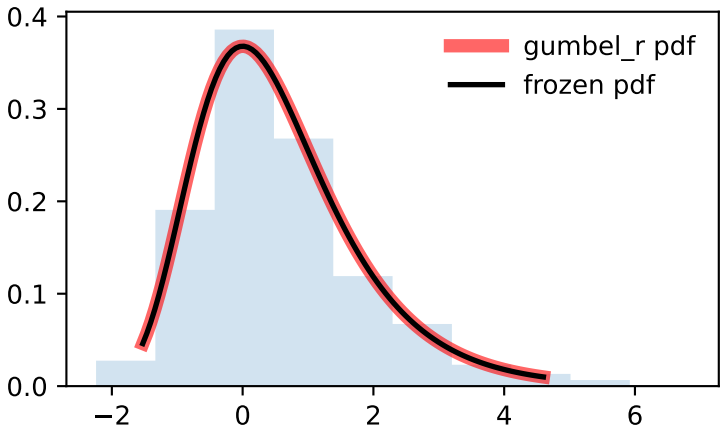
```
>>> vals = gumbel_r.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_r.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gumbel_r.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, loc=0, scale=1)	Probability density function.
logpdf(x, loc=0, scale=1)	Log of the probability density function.
cdf(x, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, loc=0, scale=1)	Log of the survival function.
ppf(q, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, loc=0, scale=1)	Non-central moment of order n
stats(loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(loc=0, scale=1)	Median of the distribution.
mean(loc=0, scale=1)	Mean of the distribution.
var(loc=0, scale=1)	Variance of the distribution.
std(loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.gumbel_l

scipy.stats.**gumbel_l = <scipy.stats._continuous_distns.gumbel_l_gen object>**

A left-skewed Gumbel continuous random variable.

As an instance of the *rv_continuous* class, *gumbel_l* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

gumbel_r, **gompertz**, **genextreme**

Notes

The probability density function for *gumbel_l* is:

$$f(x) = \exp(x - e^x)$$

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gumbel_l.pdf(x, loc, scale)` is identically equivalent to

`gumbel_l.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import gumbel_l
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = gumbel_l.stats(moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(gumbel_l.ppf(0.01),
...                 gumbel_l.ppf(0.99), 100)
>>> ax.plot(x, gumbel_l.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gumbel_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = gumbel_l()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

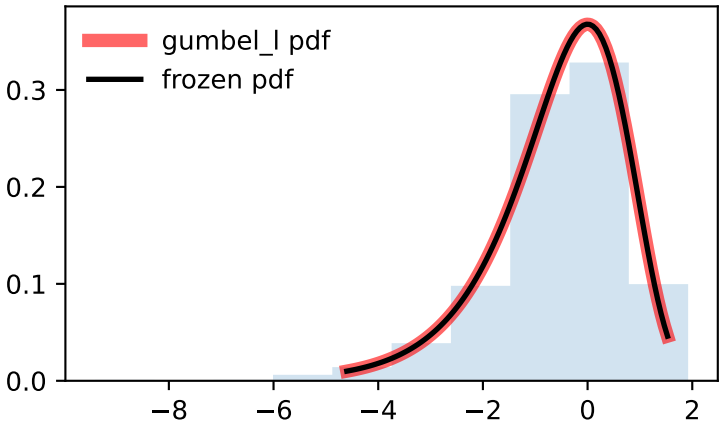
```
>>> vals = gumbel_l.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_l.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gumbel_l.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, loc=0, scale=1)	Probability density function.
logpdf(x, loc=0, scale=1)	Log of the probability density function.
cdf(x, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, loc=0, scale=1)	Log of the survival function.
ppf(q, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, loc=0, scale=1)	Non-central moment of order n
stats(loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(loc=0, scale=1)	Median of the distribution.
mean(loc=0, scale=1)	Mean of the distribution.
var(loc=0, scale=1)	Variance of the distribution.
std(loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.halfcauchy

scipy.stats.**halfcauchy = <scipy.stats._continuous_distns.halfcauchy_gen object>**

A Half-Cauchy continuous random variable.

As an instance of the *rv_continuous* class, *halfcauchy* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *halfcauchy* is:

$$f(x) = \frac{2}{\pi(1+x^2)}$$

for $x \geq 0$.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halfcauchy.pdf(x, loc, scale)` is identically equivalent to `halfcauchy.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import halfcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = halfcauchy.stats(moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(halfcauchy.ppf(0.01),
...                 halfcauchy.ppf(0.99), 100)
>>> ax.plot(x, halfcauchy.pdf(x),
...         'r-', lw=5, alpha=0.6, label='halfcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = halfcauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

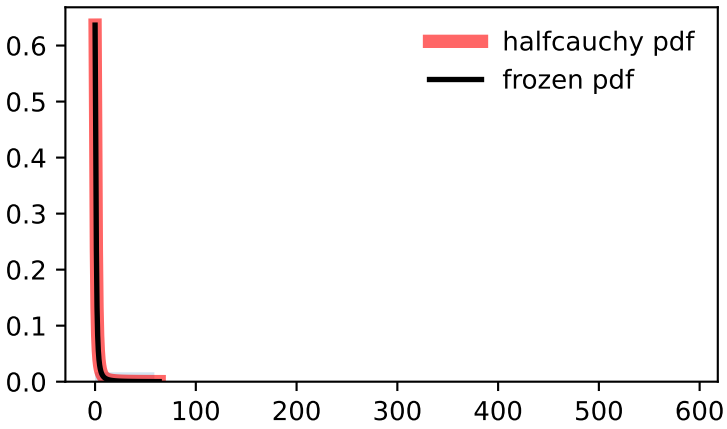
```
>>> vals = halfcauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfcauchy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halfcauchy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, loc=0, scale=1)	Probability density function.
logpdf(x, loc=0, scale=1)	Log of the probability density function.
cdf(x, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, loc=0, scale=1)	Log of the survival function.
ppf(q, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, loc=0, scale=1)	Non-central moment of order n
stats(loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(loc=0, scale=1)	Median of the distribution.
mean(loc=0, scale=1)	Mean of the distribution.
var(loc=0, scale=1)	Variance of the distribution.
std(loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.halflogistic

scipy.stats.**halflogistic = <scipy.stats._continuous_distns.halflogistic_gen object>**

A half-logistic continuous random variable.

As an instance of the *rv_continuous* class, *halflogistic* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *halflogistic* is:

$$f(x) = \frac{2e^{-x}}{(1+e^{-x})^2} = \frac{1}{2}\text{sech}(x/2)^2$$

for $x \geq 0$.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halflogistic.pdf(x, loc, scale)` is identically equivalent to `halflogistic.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import halflogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = halflogistic.stats(moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(halflogistic.ppf(0.01),
...                 halflogistic.ppf(0.99), 100)
>>> ax.plot(x, halflogistic.pdf(x),
...         'r-', lw=5, alpha=0.6, label='halflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = halflogistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

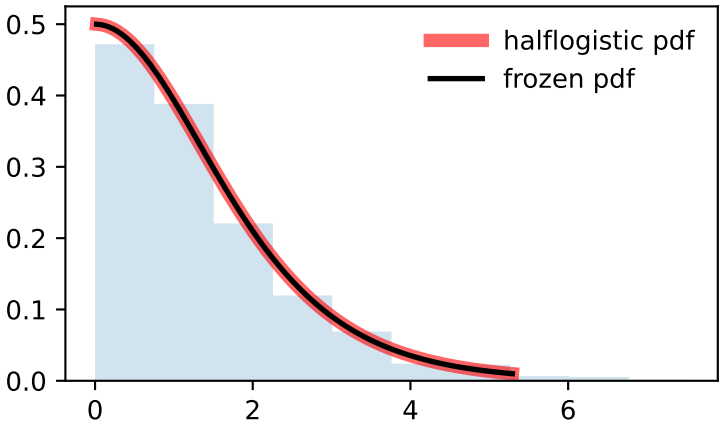
```
>>> vals = halflogistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halflogistic.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halflogistic.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, loc=0, scale=1)	Probability density function.
logpdf(x, loc=0, scale=1)	Log of the probability density function.
cdf(x, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, loc=0, scale=1)	Log of the survival function.
ppf(q, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, loc=0, scale=1)	Non-central moment of order n
stats(loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(loc=0, scale=1)	Median of the distribution.
mean(loc=0, scale=1)	Mean of the distribution.
var(loc=0, scale=1)	Variance of the distribution.
std(loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.halfnorm

scipy.stats.**halfnorm = <scipy.stats._continuous_distns.halfnorm_gen object>**

A half-normal continuous random variable.

As an instance of the *rv_continuous* class, *halfnorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *halfnorm* is:

$$f(x) = \sqrt{2/\pi}\exp(-x^2/2)$$

for $x >= 0$.

halfnorm is a special case of *chi* with `df=1`.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halfnorm.pdf(x, loc, scale)` is identically equivalent to `halfnorm.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import halfnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = halfnorm.stats(moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(halfnorm.ppf(0.01),
...                 halfnorm.ppf(0.99), 100)
>>> ax.plot(x, halfnorm.pdf(x),
...         'r-', lw=5, alpha=0.6, label='halfnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = halfnorm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

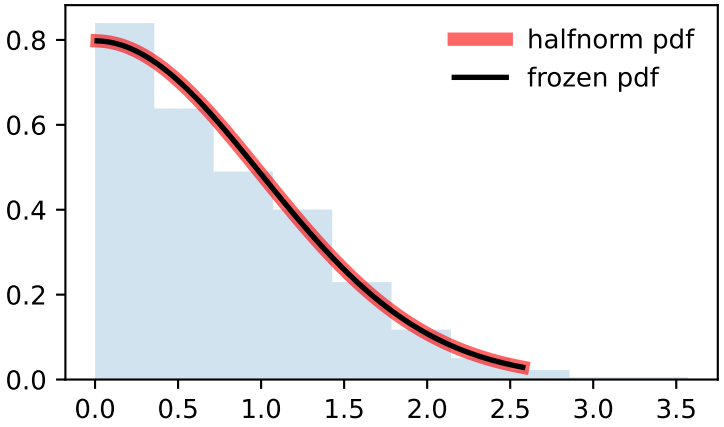
```
>>> vals = halfnorm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfnorm.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halfnorm.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, loc=0, scale=1)	Probability density function.
logpdf(x, loc=0, scale=1)	Log of the probability density function.
cdf(x, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, loc=0, scale=1)	Log of the survival function.
ppf(q, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, loc=0, scale=1)	Non-central moment of order n
stats(loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(loc=0, scale=1)	Median of the distribution.
mean(loc=0, scale=1)	Mean of the distribution.
var(loc=0, scale=1)	Variance of the distribution.
std(loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.halfgennorm

scipy.stats.**halfgennorm = <scipy.stats._continuous_distns.halfgennorm_gen object>**

The upper half of a generalized normal continuous random variable.

As an instance of the *rv_continuous* class, *halfgennorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

gennorm

generalized normal distribution

expon

exponential distribution

halfnorm

half normal distribution

Notes

The probability density function for *halfgennorm* is:

$$f(x, \beta) = \frac{\beta}{\Gamma(1/\beta)} \exp(-|x|^\beta)$$

for $x > 0$. Γ is the gamma function (*scipy.special.gamma*).

gennorm takes `beta` as a shape parameter for β. For $\beta = 1$, it is identical to an exponential distribution. For $\beta = 2$, it is identical to a half normal distribution (with `scale=1/sqrt(2)`).

References

[1]

Examples

```
>>> from scipy.stats import halfgennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> beta = 0.675
>>> mean, var, skew, kurt = halfgennorm.stats(beta, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(halfgennorm.ppf(0.01, beta),
...                 halfgennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, halfgennorm.pdf(x, beta),
...         'r-', lw=5, alpha=0.6, label='halfgennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = halfgennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

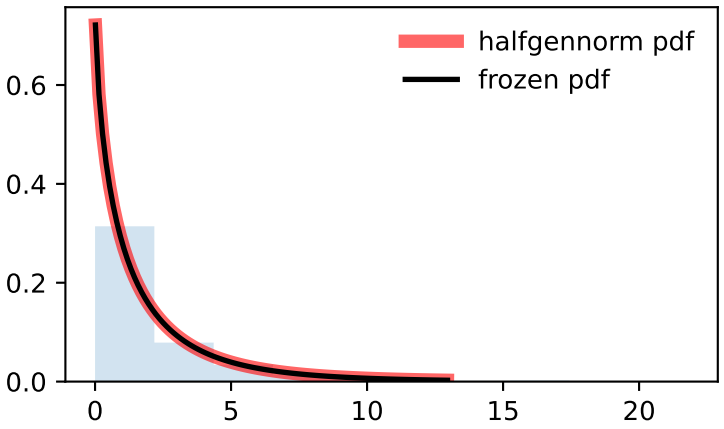
```
>>> vals = halfgennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], halfgennorm.cdf(vals, beta))
True
```

Generate random numbers:

```
>>> r = halfgennorm.rvs(beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(beta, loc=0, scale=1, size=1, random_state=None)	Random variates.

expect(func, args=(beta,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(beta, loc=0, scale=1)	Median of the distribution.
mean(beta, loc=0, scale=1)	Mean of the distribution.
var(beta, loc=0, scale=1)	Variance of the distribution.
std(beta, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, beta, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.hypsecant

scipy.stats.**hypsecant = <scipy.stats._continuous_distns.hypsecant_gen object>**

A hyperbolic secant continuous random variable.

As an instance of the *rv_continuous* class, *hypsecant* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *hypsecant* is:

$$f(x) = \frac{1}{\pi}\text{sech}(x)$$

for a real number x.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `hypsecant.pdf(x, loc, scale)` is identically equivalent to `hypsecant.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import hypsecant
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = hypsecant.stats(moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(hypsecant.ppf(0.01),
...                 hypsecant.ppf(0.99), 100)
>>> ax.plot(x, hypsecant.pdf(x),
...         'r-', lw=5, alpha=0.6, label='hypsecant pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = hypsecant()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

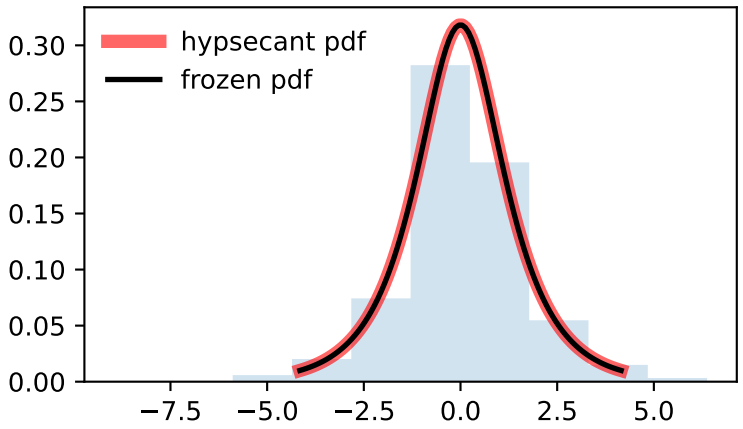
```
>>> vals = hypsecant.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], hypsecant.cdf(vals))
True
```

Generate random numbers:

```
>>> r = hypsecant.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, loc=0, scale=1)	Probability density function.
logpdf(x, loc=0, scale=1)	Log of the probability density function.
cdf(x, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, loc=0, scale=1)	Log of the survival function.
ppf(q, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, loc=0, scale=1)	Non-central moment of order n
stats(loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.

median(loc=0, scale=1)	Median of the distribution.
mean(loc=0, scale=1)	Mean of the distribution.
var(loc=0, scale=1)	Variance of the distribution.
std(loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.invgamma

scipy.stats.**invgamma = <scipy.stats._continuous_distns.invgamma_gen object>**

An inverted gamma continuous random variable.

As an instance of the *rv_continuous* class, *invgamma* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *invgamma* is:

$$f(x, a) = \frac{x^{-a-1}}{\Gamma(a)} \exp(-\frac{1}{x})$$

for $x >= 0$, $a > 0$. Γ is the gamma function (*scipy.special.gamma*).

invgamma takes `a` as a shape parameter for a.

invgamma is a special case of *gengamma* with `c=-1`, and it is a different parameterization of the scaled inverse chi-squared distribution. Specifically, if the scaled inverse chi-squared distribution is parameterized with degrees of freedom ν and scaling parameter τ^2, then it can be modeled using *invgamma* with `a=` $\nu/2$ and `scale=` $\nu\tau^2/2$.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invgamma.pdf(x, a, loc, scale)` is identically equivalent to `invgamma.pdf(y, a) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import invgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 4.07
>>> mean, var, skew, kurt = invgamma.stats(a, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(invgamma.ppf(0.01, a),
...                 invgamma.ppf(0.99, a), 100)
>>> ax.plot(x, invgamma.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='invgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = invgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

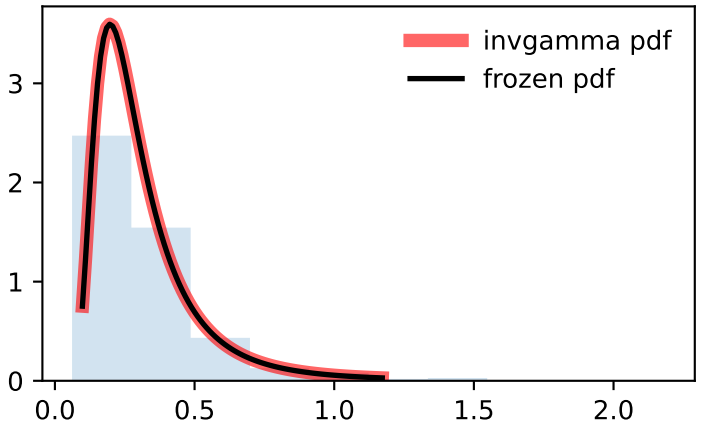
```
>>> vals = invgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], invgamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = invgamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(a, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, a, loc=0, scale=1)	Probability density function.
logpdf(x, a, loc=0, scale=1)	Log of the probability density function.
cdf(x, a, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, a, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, a, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, a, loc=0, scale=1)	Log of the survival function.
ppf(q, a, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, a, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, a, loc=0, scale=1)	Non-central moment of order n
stats(a, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(a, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(a, loc=0, scale=1)	Median of the distribution.
mean(a, loc=0, scale=1)	Mean of the distribution.
var(a, loc=0, scale=1)	Variance of the distribution.
std(a, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, a, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.invgauss

scipy.stats.**invgauss = <scipy.stats._continuous_distns.invgauss_gen object>**

An inverse Gaussian continuous random variable.

As an instance of the *rv_continuous* class, *invgauss* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *invgauss* is:

$$f(x, \mu) = \frac{1}{\sqrt{2\pi x^3}} \exp(-\frac{(x-\mu)^2}{2x\mu^2})$$

for $x >= 0$ and $\mu > 0$.

invgauss takes `mu` as a shape parameter for μ.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invgauss.pdf(x, mu, loc, scale)` is identically equivalent to `invgauss.pdf(y, mu) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import invgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mu = 0.145
>>> mean, var, skew, kurt = invgauss.stats(mu, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(invgauss.ppf(0.01, mu),
...                 invgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, invgauss.pdf(x, mu),
...         'r-', lw=5, alpha=0.6, label='invgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = invgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

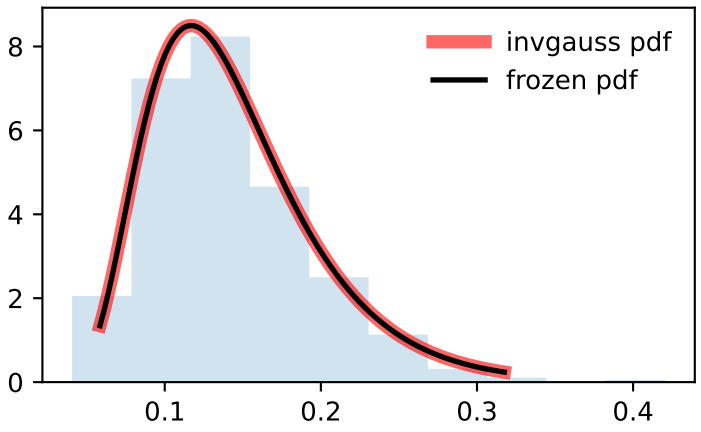
```
>>> vals = invgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], invgauss.cdf(vals, mu))
True
```

Generate random numbers:

```
>>> r = invgauss.rvs(mu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(mu, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, mu, loc=0, scale=1)	Probability density function.
logpdf(x, mu, loc=0, scale=1)	Log of the probability density function.
cdf(x, mu, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, mu, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, mu, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, mu, loc=0, scale=1)	Log of the survival function.
ppf(q, mu, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, mu, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, mu, loc=0, scale=1)	Non-central moment of order n
stats(mu, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(mu, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(mu,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(mu, loc=0, scale=1)	Median of the distribution.
mean(mu, loc=0, scale=1)	Mean of the distribution.
var(mu, loc=0, scale=1)	Variance of the distribution.
std(mu, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, mu, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.invweibull

scipy.stats.**invweibull = <scipy.stats._continuous_distns.invweibull_gen object>**

An inverted Weibull continuous random variable.

This distribution is also known as the Fréchet distribution or the type II extreme value distribution.

As an instance of the *rv_continuous* class, *invweibull* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *invweibull* is:

$$f(x, c) = cx^{-c-1} \exp(-x^{-c})$$

for $x > 0$, $c > 0$.

invweibull takes `c` as a shape parameter for c.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invweibull.pdf(x, c, loc, scale)` is identically equivalent to `invweibull.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location

of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

References

F.R.S. de Gusmao, E.M.M Ortega and G.M. Cordeiro, "The generalized inverse Weibull distribution", Stat. Papers, vol. 52, pp. 591-619, 2011.

Examples

```
>>> from scipy.stats import invweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 10.6
>>> mean, var, skew, kurt = invweibull.stats(c, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(invweibull.ppf(0.01, c),
...                 invweibull.ppf(0.99, c), 100)
>>> ax.plot(x, invweibull.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='invweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = invweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

```
>>> vals = invweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], invweibull.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = invweibull.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

std(c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.johnsonsb

scipy.stats.**johnsonsb = <scipy.stats._continuous_distns.johnsonsb_gen object>**

A Johnson SB continuous random variable.

As an instance of the *rv_continuous* class, *johnsonsb* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

johnsonsu

Notes

The probability density function for *johnsonsb* is:

$$f(x, a, b) = \frac{b}{x(1-x)}\phi(a + b\log\frac{x}{1-x})$$

where x, a, and b are real scalars; $b > 0$ and $x \in [0, 1]$. ϕ is the pdf of the normal distribution.

johnsonsb takes a and b as shape parameters.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `johnsonsb.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsb.pdf(y, a, b) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import johnsonsb
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 4.32, 3.18
>>> mean, var, skew, kurt = johnsonsb.stats(a, b, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(johnsonsb.ppf(0.01, a, b),
...                 johnsonsb.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsb.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='johnsonsb pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = johnsonsb(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

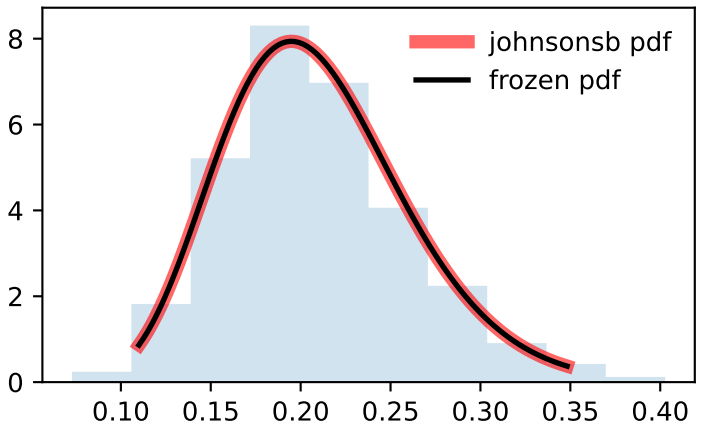
```
>>> vals = johnsonsb.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsb.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = johnsonsb.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(a, b, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, a, b, loc=0, scale=1)	Probability density function.
logpdf(x, a, b, loc=0, scale=1)	Log of the probability density function.
cdf(x, a, b, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, a, b, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, a, b, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, a, b, loc=0, scale=1)	Log of the survival function.
ppf(q, a, b, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, a, b, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, a, b, loc=0, scale=1)	Non-central moment of order n
stats(a, b, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(a, b, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(a, b, loc=0, scale=1)	Median of the distribution.
mean(a, b, loc=0, scale=1)	Mean of the distribution.
var(a, b, loc=0, scale=1)	Variance of the distribution.
std(a, b, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, a, b, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.johnsonsu

scipy.stats.**johnsonsu = <scipy.stats._continuous_distns.johnsonsu_gen object>**

A Johnson SU continuous random variable.

As an instance of the *rv_continuous* class, *johnsonsu* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

johnsonsb

Notes

The probability density function for *johnsonsu* is:

$$f(x, a, b) = \frac{b}{\sqrt{x^2 + 1}} \phi(a + b \log(x + \sqrt{x^2 + 1}))$$

where x, a, and b are real scalars; $b > 0$. ϕ is the pdf of the normal distribution.

johnsonsu takes a and b as shape parameters.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `johnsonsu.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsu.pdf(y, a, b) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import johnsonsu
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 2.55, 2.25
>>> mean, var, skew, kurt = johnsonsu.stats(a, b, moments='mvsk')
```

Display the probability density function (`pdf`):

```
>>> x = np.linspace(johnsonsu.ppf(0.01, a, b),
...                 johnsonsu.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsu.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='johnsonsu pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen `pdf`:

```
>>> rv = johnsonsu(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

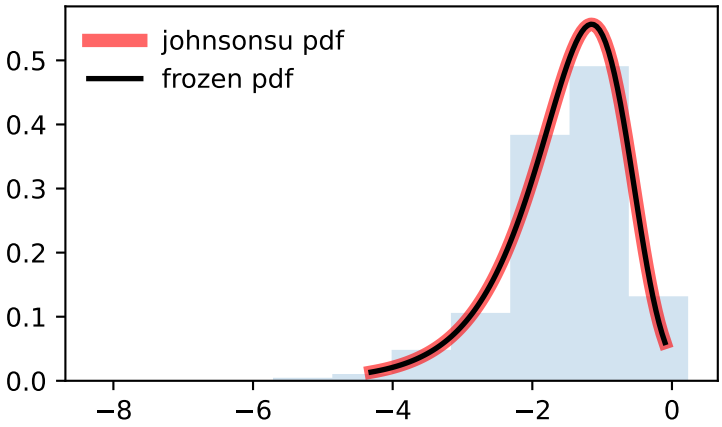
```
>>> vals = johnsonsu.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsu.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = johnsonsu.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```



Methods

rvs(a, b, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, a, b, loc=0, scale=1)	Probability density function.
logpdf(x, a, b, loc=0, scale=1)	Log of the probability density function.
cdf(x, a, b, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, a, b, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, a, b, loc=0, scale=1)	Survival function (also defined as `1 - cdf`, but *sf* is sometimes more accurate).
logsf(x, a, b, loc=0, scale=1)	Log of the survival function.
ppf(q, a, b, loc=0, scale=1)	Percent point function (inverse of `cdf` — percentiles).
isf(q, a, b, loc=0, scale=1)	Inverse survival function (inverse of `sf`).
moment(n, a, b, loc=0, scale=1)	Non-central moment of order n
stats(a, b, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(a, b, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(a, b, loc=0, scale=1)	Median of the distribution.
mean(a, b, loc=0, scale=1)	Mean of the distribution.
var(a, b, loc=0, scale=1)	Variance of the distribution.
std(a, b, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, a, b, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.kappa4

scipy.stats.**kappa4 = <scipy.stats._continuous_distns.kappa4_gen object>**

Kappa 4 parameter distribution.

As an instance of the *rv_continuous* class, *kappa4* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for kappa4 is:

$$f(x, h, k) = (1 - kx)^{1/k-1}(1 - h(1 - kx)^{1/k})^{1/h-1}$$

if h and k are not equal to 0.

If h or k are zero then the pdf can be simplified:

h = 0 and k != 0:

```
kappa4.pdf(x, h, k) = (1.0 - k*x)**(1.0/k - 1.0)*
                      exp(-(1.0 - k*x)**(1.0/k))
```

h != 0 and k = 0:

```
kappa4.pdf(x, h, k) = exp(-x)*(1.0 - h*exp(-x))**(1.0/h - 1.0)
```

h = 0 and k = 0:

```
kappa4.pdf(x, h, k) = exp(-x)*exp(-exp(-x))
```
